3. if the value \(j\) of \texttt{is\_placeholder_v<TD_i>} is not zero, the argument is \(\text{std::forward}<U_j>(u_j)\) and its type \(V_i\) is \(U_j\&\&\);
4. otherwise, the value is \(td_i\) and its type \(V_i\) is \(\text{cv} \ TD_i&\).

8 The value of the target argument \(v_{fd}\) is \(fd\) and its corresponding type \(V_{fd}\) is \(\text{cv} \ FD&\).

20.14.14 Placeholders

\[
\text{namespace std::placeholders} \{ \\
\quad // M is the implementation-defined number of placeholders \\
\quad \text{see below \_1;} \\
\quad \text{see below \_2;} \\
\quad \ldots \\
\quad \text{see below \_M;} \\
\}
\]

1 All placeholder types meet the \texttt{Cpp17DefaultConstructible} and \texttt{Cpp17CopyConstructible} requirements, and their default constructors and copy/move constructors are \texttt{constexpr} functions that do not throw exceptions. It is implementation-defined whether placeholder types meet the \texttt{Cpp17CopyAssignable} requirements, but if so, their copy assignment operators are \texttt{constexpr} functions that do not throw exceptions.

2 Placeholders should be defined as:

\[
\text{inline constexpr unspecified \_1;} \\
\]

If they are not, they are declared as:

\[
\text{extern unspecified \_1;} \\
\]

20.14.15 Function template \texttt{mem\_fn}

\[
\text{template<class R, class T> constexpr unspecified mem\_fn(R T::* pm) noexcept;} \\
\]

1 Returns: A simple call wrapper (20.14.2) \(fn\) with call pattern \(\text{invoke}(\text{pmd}, \text{call\_args}\ldots)\), where \(\text{pmd}\) is the target object of \(\text{fn}\) of type \(R\ T::*\) direct-non-list-initialized with \(\text{pm}\) and \(\text{call\_args}\) is an argument pack used in a function call expression (7.6.1.2) of \(\text{pm}\).

20.14.16 Polymorphic function wrappers

1 This subclause describes a polymorphic wrapper class that encapsulates arbitrary callable objects.

20.14.16.1 Class \texttt{bad\_function\_call}

1 An exception of type \texttt{bad\_function\_call} is thrown by \texttt{function::operator()} (20.14.16.2.4) when the function wrapper object has no target.
namespace std {
    class bad_function_call : public exception {
        public:
            // see 17.9.2 for the specification of the special member functions
            const char* what() const noexcept override;
    }
}

const char* what() const noexcept override;

Returns: An implementation-defined NTBS.

20.14.16.2 Class template function [func.wrap.func]

namespace std {
    template<class> class function;  // not defined

    template<class R, class... ArgTypes>
    class function<R(ArgTypes...)> {
        public:
            using result_type = R;
            // 20.14.16.2.1, construct/copy/destroy
            function() noexcept;
            function(nullptr_t) noexcept;
            function(const function&);
            function(function&&) noexcept;
            template<class F> function(F);
            function& operator=(const function&);
            function& operator=(function&&);
            function& operator=(nullptr_t) noexcept;
            template<class F> function& operator=(reference_wrapper<F>) noexcept;
            ~function();
            // 20.14.16.2.2, function modifiers
            void swap(function&) noexcept;
            // 20.14.16.2.3, function capacity
            explicit operator bool() const noexcept;
            // 20.14.16.2.4, function invocation
            R operator()(ArgTypes...) const;
            // 20.14.16.2.5, function target access
            const type_info& target_type() const noexcept;
            template<class T> T* target() noexcept;
            template<class T> const T* target() const noexcept;
    }

    template<class R, class... ArgTypes>
    function(R(*)(ArgTypes...)) -> function<R(ArgTypes...)>;
    template<class F> function(F) -> function<see below>;
    // 20.14.16.2.6, null pointer comparison functions
    template<class R, class... ArgTypes>
    bool operator==(const function<R(ArgTypes...)>&, nullptr_t) noexcept;
    // 20.14.16.2.7, specialized algorithms
    template<class R, class... ArgTypes>
    void swap(function<R(ArgTypes...)>&, function<R(ArgTypes...)>&) noexcept;
}

§ 20.14.2
The function class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (20.14.2), given a call signature (20.14.2), allowing functions to be first-class objects.

A callable type (20.14.2) \( F \) is \textit{Lvalue-Callable} for argument types \( \text{ArgTypes} \) and return type \( R \) if the expression \( \text{INVOKE}\, <R>(\text{declval}<F&>(), \text{declval}<\text{ArgTypes}>(), \ldots) \), considered as an unevaluated operand (7.2), is well-formed (20.14.3).

The function class template is a call wrapper (20.14.2) whose call signature (20.14.2) is \( R(\text{ArgTypes}...) \).

\[ \text{Note: The types deduced by the deduction guides for function may change in future versions of this International Standard. — end note} \]

### 20.14.16.2.1 Constructors and destructor

\[ \text{func.wrap.func.con} \]

\textbf{function()} noexcept;

\begin{verbatim}
    Postconditions: !*this.
\end{verbatim}

\textbf{function(nullptr_t) noexcept;}

\begin{verbatim}
    Postconditions: !*this.
\end{verbatim}

\textbf{function(const function& f);}

\begin{verbatim}
    Postconditions: !*this if !f; otherwise, *this targets a copy of f.target().
    Throws: Nothing if f’s target is a specialization of reference_wrapper or a function pointer. Otherwise, may throw bad_alloc or any exception thrown by the copy constructor of the stored callable object. [Note: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f’s target is an object holding only a pointer or reference to an object and a member function pointer. — end note]
\end{verbatim}

\textbf{function(function&& f) noexcept;}

\begin{verbatim}
    Postconditions: If !f, *this has no target; otherwise, the target of *this is equivalent to the target of f before the construction, and f is in a valid state with an unspecified value.
    [Note: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f’s target is an object holding only a pointer or reference to an object and a member function pointer. — end note]
\end{verbatim}

\textbf{template<class F> function(F f);}  

\begin{verbatim}
    Constraints: F is Lvalue-Callable (20.14.16.2) for argument types ArgTypes... and return type R.
    Preconditions: F meets the Cpp17CopyConstructible requirements.
    Postconditions: !*this if any of the following hold:
    \begin{enumerate}
      \item f is a null function pointer value.
      \item f is a null member pointer value.
      \item F is an instance of the function class template, and !f.
    \end{enumerate}
    Otherwise, *this targets a copy of f initialized with std::move(f). [Note: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f is an object holding only a pointer or reference to an object and a member function pointer. — end note]
    Throws: Nothing if f is a specialization of reference_wrapper or a function pointer. Otherwise, may throw bad_alloc or any exception thrown by F’s copy or move constructor.
\end{verbatim}

\textbf{template<class F> function(F) -> function<see below>;}

\begin{verbatim}
    Constraints: \&F::operator() is well-formed when treated as an unevaluated operand and decltype(\&F::operator()) is of the form R(G::*)(A...) \&opt noexcept_opt for a class type G.
    Remarks: The deduced type is function<R(A...)>.  
    [Example:
      void f() {
        int i{5};
    \end{verbatim}
function g = [k](double) { return i; };       // deduces function<int(double)>

— end example]

function& operator=(const function& f);
15 Effects: As if by function(f).swap(*this);
16 Returns: *this.

function& operator=(function&& f);
17 Effects: Replaces the target of *this with the target of f.
18 Returns: *this.

function& operator=(nullptr_t) noexcept;
19 Effects: If *this != nullptr, destroys the target of this.
20 Postconditions: !(*this).
21 Returns: *this.

template<class F> function& operator=(F&& f);
22 Constraints: decay_t<F> is Lvalue-Callable (20.14.16.2) for argument types ArgTypes... and return type R.
23 Effects: As if by: function(std::forward<F>(f)).swap(*this);
24 Returns: *this.

template<class F> function& operator=(reference_wrapper<F> f) noexcept;
25 Effects: As if by: function(f).swap(*this);
26 Returns: *this.

~function();
27 Effects: If *this != nullptr, destroys the target of this.

20.14.16.2.2 Modifiers

void swap(function& other) noexcept;
1 Effects: Interchanges the targets of *this and other.

20.14.16.2.3 Capacity

explicit operator bool() const noexcept;
1 Returns: true if *this has a target, otherwise false.

20.14.16.2.4 Invocation

R operator()(ArgTypes... args) const;
1 Returns: INVOKE<R>(f, std::forward<ArgTypes>(args)...) (20.14.3), where f is the target object (20.14.4) of *this.
2 Throws: bad_function_call if !*this; otherwise, any exception thrown by the wrapped callable object.

20.14.16.2.5 Target access

cast type_info& target_type() const noexcept;
1 Returns: If *this has a target of type T, typeid(T); otherwise, typeid(void).

template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;
2 Returns: If target_type() == typeid(T) a pointer to the stored function target; otherwise a null pointer.

§ 20.14.2.5
20.14.16.2.6 Null pointer comparison functions

```
template<class R, class... ArgTypes>
  bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
```

1. Returns: `!f`.

20.14.16.2.7 Specialized algorithms

```
template<class R, class... ArgTypes>
  void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;
```

1. Effects: As if by: `f1.swap(f2)`.

20.14.17 Searchers

This subclause provides function object types (20.14) for operations that search for a sequence `[pat_first, pat_last)` in another sequence `[first, last)` that is provided to the object's function call operator. The first sequence (the pattern to be searched for) is provided to the object's constructor, and the second (the sequence to be searched) is provided to the function call operator.

Each specialization of a class template specified in this subclause 20.14.17 shall meet the Cpp17CopyConstructible and Cpp17CopyAssignable requirements. Template parameters named

1. ForwardIterator,
2. ForwardIterator1,
3. ForwardIterator2,
4. RandomAccessIterator,
5. RandomAccessIterator1,
6. RandomAccessIterator2, and
7. BinaryPredicate

of templates specified in this subclause 20.14.17 shall meet the same requirements and semantics as specified in 25.1. Template parameters named Hash shall meet the Cpp17Hash requirements (Table 34).

The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

20.14.17.1 Class template default_searcher

```
template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
  class default_searcher {
    public:
      constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                               BinaryPredicate pred = BinaryPredicate());
      template<class ForwardIterator2>
      constexpr pair<ForwardIterator2, ForwardIterator2>
        operator()(ForwardIterator2 first, ForwardIterator2 last) const;
    private:
      ForwardIterator1 pat_first_;  // exposition only
      ForwardIterator1 pat_last_;   // exposition only
      BinaryPredicate pred_;        // exposition only
    };
```

```
constexpr default_searcher(ForwardIterator pat_first, ForwardIterator pat_last,
                           BinaryPredicate pred = BinaryPredicate());
```

1. Effects: Constructs a default_searcher object, initializing `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, and `pred_` with `pred`.

2. Throws: Any exception thrown by the copy constructor of `BinaryPredicate` or `ForwardIterator1`.

§ 20.14.17.1
```cpp
template<class ForwardIterator2>
constexpr pair<ForwardIterator2, ForwardIterator2>
operator()(ForwardIterator2 first, ForwardIterator2 last) const;
```

Effects: Returns a pair of iterators i and j such that

(3.1) \( i == \text{search}(\text{first}, \text{last}, \text{pat}_\text{first}_-, \text{pat}_\text{last}_-, \text{pred}_-) \), and

(3.2) if \( i == \text{last} \), then \( j == \text{last} \), otherwise \( j == \text{next}(i, \text{distance}(\text{pat}_\text{first}_-, \text{pat}_\text{last}_-)) \).

### 20.14.17.2 Class template boyer_moore_searcher

```cpp
template<class RandomAccessIterator1,
class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
class BinaryPredicate = equal_to<>>
class boyer_moore_searcher {
public:
    boyer_moore_searcher(RandomAccessIterator1 pat_first,
                         RandomAccessIterator1 pat_last,
                         Hash hf = Hash(),
                         BinaryPredicate pred = BinaryPredicate());

    template<class RandomAccessIterator2>
    pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

private:
    RandomAccessIterator1 pat_first_; // exposition only
    RandomAccessIterator1 pat_last_; // exposition only
    Hash hash_; // exposition only
    BinaryPredicate pred_; // exposition only
};
```

boyer_moore_searcher(RandomAccessIterator1 pat_first,
                      RandomAccessIterator1 pat_last,
                      Hash hf = Hash(),
                      BinaryPredicate pred = BinaryPredicate());

Preconditions: The value type of RandomAccessIterator1 meets the C++17DefaultConstructible requirements,
the C++17CopyConstructible requirements, and the C++17CopyAssignable requirements.

Let V be iterator_traits<RandomAccessIterator1>::value_type. For any two values A and B of type V,
if \( \text{pred}(A, B) == \text{true} \), then \( \text{hf}(A) == \text{hf}(B) \) is true.

Effects: Initializes \( \text{pat}_\text{first}_- \) with \( \text{pat}_\text{first} \), \( \text{pat}_\text{last}_- \) with \( \text{pat}_\text{last} \), \( \text{hash}_- \) with \( \text{hf} \), and \( \text{pred}_- \) with \( \text{pred} \).

Throws: Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default
constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1,
or the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc if additional
memory needed for internal data structures cannot be allocated.

```cpp
template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

Mandates: RandomAccessIterator1 and RandomAccessIterator2 have the same value type.

Effects: Finds a subsequence of equal values in a sequence.

Returns: A pair of iterators i and j such that

(7.1) \( i \) is the first iterator in the range \([\text{first}, \text{last} - (\text{pat}_\text{last}_- - \text{pat}_\text{first}_-)) \) such that for every non-negative integer n less than \( \text{pat}_\text{last}_- - \text{pat}_\text{first}_- \) the following condition holds: \( \text{pred}(*(i + n), *(\text{pat}_\text{first}_- + n)) \) != false, and

(7.2) \( j == \text{next}(i, \text{distance}(\text{pat}_\text{first}_-, \text{pat}_\text{last}_-)) \).

Returns make_pair(first, first) if \([\text{pat}_\text{first}_-, \text{pat}_\text{last}_-) \) is empty, otherwise returns make_pair(last, last) if no such iterator is found.

Complexity: At most \((\text{last} - \text{first}) \ast (\text{pat}_\text{last}_- - \text{pat}_\text{first}_-) \) applications of the predicate.

§ 20.14.17.2

20.14.17.3 Class template **boyer_moore_horspool_searcher**

```cpp
template<class RandomAccessIterator1,
         class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
         class BinaryPredicate = equal_to<>
         >
class boyer_moore_horspool_searcher {
public:
  boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                             RandomAccessIterator1 pat_last,
                             Hash hf = Hash(),
                             BinaryPredicate pred = BinaryPredicate());

  template<class RandomAccessIterator2>
  pair<RandomAccessIterator2, RandomAccessIterator2>
  operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

private:
  RandomAccessIterator1 pat_first_;  // exposition only
  RandomAccessIterator1 pat_last_;   // exposition only
  Hash hash_;                       // exposition only
  BinaryPredicate pred_;            // exposition only
};
```

```cpp
boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                              RandomAccessIterator1 pat_last,
                              Hash hf = Hash(),
                              BinaryPredicate pred = BinaryPredicate());
```

1. **Preconditions:** The value type of RandomAccessIterator1 meets the Cpp17DefaultConstructible, Cpp17CopyConstructible, and Cpp17CopyAssignable requirements.
2. Let $V$ be `iterator_traits<RandomAccessIterator1>::value_type`. For any two values $A$ and $B$ of type $V$, if $\text{pred}(A, B) == \text{true}$, then $\text{hf}(A) == \text{hf}(B)$ is true.
3. **Effects:** Initializes `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, `hash_` with `hf`, and `pred_` with `pred`.
4. **Throws:** Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1 or the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc if additional memory needed for internal data structures cannot be allocated.

```cpp
template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

5. **Mandates:** RandomAccessIterator1 and RandomAccessIterator2 have the same value type.
6. **Effects:** Finds a subsequence of equal values in a sequence.
7. **Returns:** A pair of iterators $i$ and $j$ such that
   - $i$ is the first iterator $i$ in the range $[\text{first}, \text{last} - (\text{pat_last_} - \text{pat_first_}))$ such that for every non-negative integer $n$ less than $\text{pat_last_} - \text{pat_first_}$ the following condition holds: $\text{pred}(*(i + n), *(\text{pat_first_} + n)) != \text{false}$, and
   - $j == \text{next}(i, \text{distance}(\text{pat_first_}, \text{pat_last_}))$.
   Returns `make_pair(first, first)` if $\text{pat_first_}$, $\text{pat_last_}$ is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.
8. **Complexity:** At most $(\text{last} - \text{first}) * (\text{pat_last_} - \text{pat_first_})$ applications of the predicate.

### 20.14.18 Class template **hash**

1. The unordered associative containers defined in 22.5 use specializations of the class template `hash` (20.14.1) as the default hash function.
2. Each specialization of `hash` is either enabled or disabled, as described below. [Note: Enabled specializations meet the Cpp17Hash requirements, and disabled specializations do not. — end note] Each header that declares the template `hash` provides enabled specializations of `hash` for `nullptr_t` and all cv-unqualified arithmetic, enumeration, and...
pointer types. For any type Key for which neither the library nor the user provides an explicit or partial specialization of the class template hash, hash<Key> is disabled.

3 If the library provides an explicit or partial specialization of hash<Key>, that specialization is enabled except as noted otherwise, and its member functions are noexcept except as noted otherwise.

4 If H is a disabled specialization of hash, these values are false: is_default_constructible_v<H>, is_copy_constructible_v<H>, is_move_constructible_v<H>, is_copyAssignable_v<H>, and is_move_Assignable_v<H>. Disabled specializations of hash are not function object types (20.14). [Note: This means that the specialization of hash exists, but any attempts to use it as a Cpp17Hash will be ill-formed. — end note]

An enabled specialization hash<Key> will:

(5.1) meet the Cpp17Hash requirements (Table 34), with Key as the function call argument type, the Cpp17DefaultConstructible requirements (Table 27), the Cpp17CopyAssignable requirements (Table 31),

(5.2) be swappable (16.5.3.2) for lvalues,

(5.3) meet the requirement that if k1 == k2 is true, h(k1) == h(k2) is also true, where h is an object of type hash<Key> and k1 and k2 are objects of type Key;

(5.4) meet the requirement that the expression h(k), where h is an object of type hash<Key> and k is an object of type Key, shall not throw an exception unless hash<Key> is a program-defined specialization that depends on at least one program-defined type.

20.15 Metaprogramming and type traits [meta]

This subclause describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimise template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.

1 All functions specified in this subclause are signal-safe (17.13.4).

20.15.1 Requirements [meta.rqmts]

1 A Cpp17UnaryTypeTrait describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be Cpp17DefaultConstructible, Cpp17CopyConstructible, and publicly and unambiguously derived, directly or indirectly, from its base characteristic, which is a specialization of the template integral_constant (20.15.3), with the arguments to the template integral_constant determined by the requirements for the particular property being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the Cpp17UnaryTypeTrait.

2 A Cpp17BinaryTypeTrait describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be Cpp17DefaultConstructible, Cpp17CopyConstructible, and publicly and unambiguously derived, directly or indirectly, from its base characteristic, which is a specialization of the template integral_constant (20.15.3), with the arguments to the template integral_constant determined by the requirements for the particular relationship being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the Cpp17BinaryTypeTrait.

3 A Cpp17TransformationTrait modifies a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the modification. It shall define a publicly accessible nested type named type, which shall be a synonym for the modified type.

4 Unless otherwise specified, the behavior of a program that adds specializations for any of the templates specified in this subclause 20.15 is undefined.

5 Unless otherwise specified, an incomplete type may be used to instantiate a template specified in this subclause. The behavior of a program is undefined if:

(5.1) an instantiation of a template specified in subclause 20.15 directly or indirectly depends on an incompletely-defined object type T, and

(5.2) that instantiation could yield a different result were T hypothetically completed.

// 20.15.10, constant evaluation context
constexpr bool is_constant_evaluated() noexcept;
}

20.15.3 Helper classes
namespace std {
template<class T, T v> struct integral_constant {
  static constexpr T value = v;

  using value_type = T;
  using type = integral_constant<T, v>;

  constexpr operator value_type() const noexcept { return value; }
  constexpr value_type operator()() const noexcept { return value; }
};
}

The class template integral_constant, alias template bool_constant, and its associated type names true_type and false_type are used as base classes to define the interface for various type traits.

20.15.4 Unary type traits
This subclause contains templates that may be used to query the properties of a type at compile time.

Each of these templates shall be a Cpp17UnaryTypeTrait (20.15.1) with a base characteristic of true_type if the corresponding condition is true, otherwise false_type.

§ 20.15.4
20.15.4.1 Primary type categories

The primary type categories correspond to the descriptions given in subclause 6.8 of the C++ standard. For any given type \( T \), the result of applying one of these templates to \( T \) and to \( cvT \) shall yield the same result. [Note: For any given type \( T \), exactly one of the primary type categories has a value member that evaluates to \text{true}. — end note]

Table 47: Primary type category predicates

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt; struct is_void;</td>
<td>( T ) is void</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_null_pointer;</td>
<td>( T ) is \text{nullptr_t} (6.8.1)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_integral;</td>
<td>( T ) is an integral type (6.8.1)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_floating_point;</td>
<td>( T ) is a floating-point type (6.8.1)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_array;</td>
<td>( T ) is an array type (6.8.2) of known or unknown extent</td>
<td>Class template array (22.3.7) is not an array type.</td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_pointer;</td>
<td>( T ) is a pointer type (6.8.2)</td>
<td>Includes pointers to functions but not pointers to non-static members.</td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_lvalue_reference;</td>
<td>( T ) is an lvalue reference type (9.3.3.2)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_rvalue_reference;</td>
<td>( T ) is an rvalue reference type (9.3.3.2)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_member_object_pointer;</td>
<td>( T ) is a pointer to data member</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_member_function_pointer;</td>
<td>( T ) is a pointer to member function</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_enum;</td>
<td>( T ) is an enumeration type (6.8.2)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_union;</td>
<td>( T ) is a union type (6.8.2)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_class;</td>
<td>( T ) is a non-union class type (6.8.2)</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct is_function;</td>
<td>( T ) is a function type (6.8.2)</td>
<td></td>
</tr>
</tbody>
</table>

20.15.4.2 Composite type traits

These templates provide convenient compositions of the primary type categories, corresponding to the descriptions given in subclause 6.8.

For any given type \( T \), the result of applying one of these templates to \( T \) and to \( cvT \) shall yield the same result.

Table 48: Composite type category predicates

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>

<td><code>struct is_member_pointer;</code></td>
<td>T is a pointer-to-member type (6.8.2)</td>
</tr>
</tbody>
</table>

20.15.4.3 Type properties

These templates provide access to some of the more important properties of types.

It is unspecified whether the library defines any full or partial specializations of any of these templates.

For all of the class templates X declared in this subclause, instantiating that template with a template-argument that is a class template specialization may result in the implicit instantiation of the template argument if and only if the semantics of X require that the argument is a complete type.

For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type T is considered to be a trivial (6.8, 11.4.3) function call that is not an odr-use (6.3) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 20.2.6.

Table 49: Type property predicates

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Preconditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>`template&lt;class T&gt;</td>
<td><code>struct is_const;</code></td>
<td>T is const-qualified (6.8.3)</td>
</tr>
<tr>
<td>`template&lt;class T&gt;</td>
<td><code>struct is_volatile;</code></td>
<td>T is volatile-qualified (6.8.3)</td>
</tr>

</tr>
<tr>
<td>template&lt;class T&gt; struct is_nothrow_destructible;</td>
<td>is_destructible_v&lt;T&gt; is true and the indicated destructor is known not to throw any exceptions (7.6.2.6).</td>
<td>T shall be a complete type, cv void, or an array of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class T&gt; struct has_virtual_destructor;</td>
<td>T has a virtual destructor (11.4.6)</td>
<td>If T is a non-union class type, T shall be a complete type.</td>
</tr>
<tr>
<td>template&lt;class T&gt; struct has_unique_object_representations;</td>
<td>For an array type T, the same result as has_unique_object_representations_v&lt;remove_all_extents_v&lt;T&lt;T&gt;&gt;, otherwise see below</td>
<td>T shall be a complete type, cv void, or an array of unknown bound.</td>
</tr>
</tbody>
</table>

5 **Example:**

- is_const_v<volatile int> //true
- is_const_v<const int*> //false
- is_const_v<const int&> //false
is_const_v<int[3]> // false
is_const_v<const int[3]> // true

— end example]

6 [Example:

```cpp
remove_const_t<const volatile int>  // volatile int
remove_const_t<const int* const>   // const int*
remove_const_t<const int&>         // const int&
```

— end example]

7 [Example:

```cpp
// Given:
struct P final { };
union U1 { };
union U2 final { };

// the following assertions hold:
static_assert(!is_final_v<int>);
static_assert(is_final_v<P>);
static_assert(!is_final_v<U1>);
static_assert(is_final_v<U2>);

— end example]

8 The predicate condition for a template specialization is_constructible<T, Args...> shall be satisfied if and only if the following variable definition would be well-formed for some invented variable t:

```
T t(declval<Args>()...);
```

[Note: These tokens are never interpreted as a function declaration. — end note] Access checking is performed as if in a context unrelated to T and any of the Args. Only the validity of the immediate context of the variable initialization is considered. [Note: The evaluation of the initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

9 The predicate condition for a template specialization has_unique_object_representations<T> shall be satisfied if and only if:

1. T is trivially copyable, and
2. any two objects of type T with the same value have the same object representation, where two objects of array or non-union class type are considered to have the same value if their respective sequences of direct subobjects have the same values, and two objects of union type are considered to have the same value if they have the same active member and the corresponding members have the same value.

The set of scalar types for which this condition holds is implementation-defined. [Note: If a type has padding bits, the condition does not hold; otherwise, the condition holds true for integral types. — end note]

20.15.5 Type property queries [meta.unary.prop.query]

This subclause contains templates that may be used to query properties of types at compile time.

<table>
<thead>
<tr>
<th>Template</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt;</td>
<td>alignof(T).</td>
</tr>
<tr>
<td>struct alignment_of;</td>
<td>Mandates: alignof(T) is a valid expression (7.6.2.5)</td>
</tr>
<tr>
<td>template&lt;class T&gt;</td>
<td>If T names an array type, an integer value representing the number of dimensions of T; otherwise, 0.</td>
</tr>
<tr>
<td>struct rank;</td>
<td>If T is not an array type, or if it has rank less than or equal to I, or if I is 0 and T has type &quot;array of unknown bound of U&quot;, then 0; otherwise, the bound (9.3.3.4) of the Ith dimension of T, where indexing of I is zero-based</td>
</tr>
<tr>
<td>template&lt;class T, unsigned I = 0&gt;</td>
<td>structural_extent;</td>
</tr>
</tbody>
</table>

§ 20.15.5
Example:

// the following assertions hold:
assert(rank_v<int> == 0);
assert(rank_v<int[2]> == 1);
assert(rank_v<int[2][4]> == 2);

— end example

Example:

// the following assertions hold:
assert(extent_v<int> == 0);
assert(extent_v<int[2]> == 2);
assert(extent_v<int[2][4]> == 2);
assert((extent_v<int, 1>) == 0);
assert((extent_v<int[2], 1>) == 0);
assert((extent_v<int[2][4], 1>) == 4);
assert((extent_v<int[][], 1>) == 4);

— end example

### 20.15.6 Relationships between types

This subclause contains templates that may be used to query relationships between types at compile time.

Each of these templates shall be a `Cpp17BinaryTypeTrait` (20.15.1) with a base characteristic of `true_type` if the corresponding condition is true, otherwise `false_type`.

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T, class U&gt; struct is_same;</code></td>
<td>T and U name the same type with the same cv-qualifications</td>
<td></td>
</tr>
<tr>
<td><code>template&lt;class Base, class Derived&gt; struct is_base_of;</code></td>
<td>Base is a base class of Derived (11.7) without regard to cv-qualifiers or Base and Derived are not unions and name the same class type without regard to cv-qualifiers</td>
<td>If Base and Derived are non-union class types and are not possibly cv-qualified versions of the same type, Derived shall be a complete type. [Note: Base classes that are private, protected, or ambiguous are, nonetheless, base classes. — end note]</td>
</tr>
<tr>
<td><code>template&lt;class From, class To&gt; struct is_convertible;</code></td>
<td><code>is_convertible_v&lt;From, To&gt;</code> is true and the conversion, as defined by <code>is_convertible</code>, is known not to throw any exceptions (7.6.2.6)</td>
<td>From and To shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td><code>template&lt;class From, class To&gt; struct is_nothrow_convertible;</code></td>
<td><code>is_nothrow_convertible_v&lt;From, To&gt;</code></td>
<td>From and To shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td><code>template&lt;class T, class U&gt; struct is_layout_compatible;</code></td>
<td>T and U are layout-compatible (6.8)</td>
<td>T and U shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td><code>template&lt;class Base, class Derived&gt; struct is_pointer_interconvertible_base_of;</code></td>
<td>Derived is unambiguously derived from Base without regard to cv-qualifiers, and each object of type Derived is pointer-interconvertible (6.8.2) with its Base subobject, or Base and Derived are not unions and name the same class type without regard to cv-qualifiers.</td>
<td>If Base and Derived are non-union class types and are not (possibly cv-qualified versions of) the same type, Derived shall be a complete type.</td>
</tr>
</tbody>
</table>
Table 51: Type relationship predicates (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class Fn, class... ArgTypes&gt; struct is_invocable;</td>
<td>The expression <code>INVOKEDeclval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...</code> is well-formed when treated as an unevaluated operand</td>
<td>Fn and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class R, class Fn, class... ArgTypes&gt; struct is_invocable_r;</td>
<td>The expression <code>INVOKER&lt;R&gt;(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is well-formed when treated as an unevaluated operand</td>
<td>Fn, R, and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class Fn, class... ArgTypes&gt; struct is_nothrow_invocable;</td>
<td><code>is_invocable_v&lt;Fn, ArgTypes...&gt;</code> is true and the expression <code>INVOKEDeclval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...</code> is known not to throw any exceptions (7.6.2.6)</td>
<td>Fn and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class R, class Fn, class... ArgTypes&gt; struct is_nothrow_invocable_r;</td>
<td><code>is_invocable_v&lt;R, Fn, ArgTypes...&gt;</code> is true and the expression <code>INVOKER&lt;R&gt;(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is known not to throw any exceptions (7.6.2.6)</td>
<td>Fn, R, and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
</tbody>
</table>

3 For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type T is considered to be a trivial (6.8, 11.4.3) function call that is not an odr-use (6.3) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 20.2.6.

4 [Example:

```
struct B {};  
struct B1 : B {};  
struct B2 : B {};  
struct D : private B1, private B2 {};  

is_base_of_v<B, D>    //true  
is_base_of_v<const B, D> //true  
is_base_of_v<B, const D> //true  
is_base_of_v<B, const B> //true  
is_base_of_v<D, B>     //false  
is_base_of_v<B&, D&>   //false  
is_base_of_v<B[3], D[3]> //false  
is_base_of_v<int, int> //false  
```

—end example]

5 The predicate condition for a template specialization `is_convertible<From, To>` shall be satisfied if and only if the return expression in the following code would be well-formed, including any implicit conversions to the return type of the function:

```
To test() {
    return declval<From>();
}
```

[Note: This requirement gives well-defined results for reference types, void types, array types, and function types. —end note] Access checking is performed in a context unrelated to To and From. Only the validity of the immediate context of the expression of the return statement (8.7.3) (including initialization of the returned object or reference) is considered. [Note: The initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. —end note]
20.15.7 Transformations between types [meta.trans]

This subclause contains templates that may be used to transform one type to another following some predefined rule.

20.15.7.1 Const-volatile modifications [meta.trans.cv]

Table 52: Const-volatile modifications [tab:meta.trans.cv]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
struct remove_const;
| The member typedef type names the same type as T except that any top-level const-qualifier has been removed. [Example: remove_const_t<const volatile int> evaluates to volatile int, whereas remove_const_t<const int*> evaluates to const int*. — end example] |
| template<class T>
struct remove_volatile;
| The member typedef type names the same type as T except that any top-level volatile-qualifier has been removed. [Example: remove_volatile_t<const volatile int> evaluates to const int, whereas remove_volatile_t<const volatile int*> evaluates to volatile int*. — end example] |
| template<class T>
struct remove_cv;
| The member typedef type shall be the same as T except that any top-level cv-qualifier has been removed. [Example: remove_cv_t<const volatile int> evaluates to int, whereas remove_cv_t<const volatile int*> evaluates to volatile int*. — end example] |
| template<class T>
struct add_const;
| If T is a reference, function, or top-level const-qualified type, then type names the same type as T, otherwise T const. |
| template<class T>
struct add_volatile;
| If T is a reference, function, or top-level volatile-qualified type, then type names the same type as T, otherwise T volatile. [Note: This rule reflects the semantics of reference collapsing (9.3.3.2).] |
| template<class T>
struct add_cv;
| The member typedef type names the same type as add_const_t<add_volatile_t<T>>. |

20.15.7.2 Reference modifications [meta.trans.ref]

Table 53: Reference modifications [tab:meta.trans.ref]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
struct remove_reference;
| If T has type "reference to T1" then the member typedef type names T1; otherwise, type names T. |
| template<class T>
struct add_lvalue_reference;
| If T names a referenceable type (16.3.23) then the member typedef type names T&; otherwise, type names T. [Note: This rule reflects the semantics of reference collapsing (9.3.3.2).] |
| template<class T>
struct add_rvalue_reference;
| If T names a referenceable type then the member typedef type names T&&; otherwise, type names T. [Note: This rule reflects the semantics of reference collapsing (9.3.3.2). For example, when a type T names a type T1&, the type add_rvalue_reference_t<T> is not an rvalue reference. — end note] |

20.15.7.3 Sign modifications [meta.trans.sign]

Table 54: Sign modifications [tab:meta.trans.sign]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
struct make_signed;
| If T names a (possibly cv-qualified) signed integer type (6.8.1) then the member typedef type names the type T; otherwise, if T names a (possibly cv-qualified) unsigned integer type then type names the corresponding signed integer type, with the same cv-qualifiers as T; otherwise, type names the signed integer type with smallest rank (6.8.4) for which sizeof(T) == sizeof(type), with the same cv-qualifiers as T. Mandates: T is an integral or enumeration type other than cv bool. |

§ 20.15.7.3 689
### Table 54: Sign modifications (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt; struct make_unsigned;</td>
<td>If ( T ) names a (possibly cv-qualified) unsigned integer type (6.8.1) then the member typedef( \text{type} ) names the type ( T ); otherwise, if ( T ) names a (possibly cv-qualified) signed integer type then ( \text{type} ) names the corresponding unsigned integer type, with the same cv-qualifiers as ( T ); otherwise, ( \text{type} ) names the unsigned integer type with smallest rank (6.8.4) for which ( \text{sizeof}(T) = \text{sizeof}(\text{type}) ), with the same cv-qualifiers as ( T ). <em>Mandates:</em> ( T ) is an integral or enumeration type other than cv bool.</td>
</tr>
</tbody>
</table>

### 20.15.7.4 Array modifications

#### Table 55: Array modifications  
[tab:meta.trans.arr]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt; struct remove_extent;</td>
<td>If ( T ) names a type &quot;array of ( U )“, the member typedef( \text{type} ) shall be ( U ), otherwise ( T ). [Note: For multidimensional arrays, only the first array dimension is removed. For a type &quot;array of const ( U )“, the resulting type is const ( U ). — end note]</td>
</tr>
<tr>
<td>template&lt;class T&gt; struct remove_all_extents;</td>
<td>If ( T ) is &quot;multi-dimensional array of ( U )“, the resulting member typedef( \text{type} ) is ( U ), otherwise ( T ).</td>
</tr>
</tbody>
</table>

1 [Example:

```
// the following assertions hold:
assert((is_same_v<remove_extent_t<int>, int>));
assert((is_same_v<remove_extent_t<int[2], int>));
assert((is_same_v<remove_extent_t<int[2][3], int[3]>>));
assert((is_same_v<remove_extent_t<int[3], int[3]>>));
```

— end example]

2 [Example:

```
// the following assertions hold:
assert((is_same_v<remove_all_extents_t<int>, int>));
assert((is_same_v<remove_all_extents_t<int[2], int>));
assert((is_same_v<remove_all_extents_t<int[2][3], int>>));
assert((is_same_v<remove_all_extents_t<int[3], int>>));
```

— end example]

### 20.15.7.5 Pointer modifications

#### Table 56: Pointer modifications  
[tab:meta.trans.ptr]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt; struct remove_pointer;</td>
<td>If ( T ) has type &quot;(possibly cv-qualified) pointer to ( T1 )&quot; then the member typedef( \text{type} ) names ( T1 ); otherwise, it names ( T ).</td>
</tr>
<tr>
<td>template&lt;class T&gt; struct add_pointer;</td>

| template<
| size_t Len,
| size_t Align
| = default-alignment>
| struct aligned_storage;                                                 | The value of default-alignment shall be the most stringent alignment requirement for any object type whose size is no greater than Len (6.8). The member typedef type shall be a trivial standard-layout type suitable for use as uninitialized storage for any object whose size is at most Len and whose alignment is a divisor of Align. Mandates: Len is not zero. Align is equal to alignof(T) for some type T or to default-alignment. |
| template<size_t Len,
| class... Types>
| struct aligned_union;                                                  | The member typedef type shall be a trivial standard-layout type suitable for use as uninitialized storage for any object whose type is listed in Types; its size shall be at least Len. The static member alignment_value shall be an integral constant of type size_t whose value is the strictest alignment of all types listed in Types. Mandates: At least one type is provided. Each type in the template parameter pack Types is a complete object type. |
| template<class T>                                                       | The member typedef type names the same type as remove_cv_t<remove_reference_t<T>>.                                                       |
| template<class T>                                                       | Let U be remove_reference_t<T>. If is_array_v<U> is true, the member typedef type equals remove_extent_t<U>*. If is_function_v<U> is true, the member typedef type equals add_pointer_t<U>. Otherwise the member typedef type equals remove_cv_t<U>. [Note: This behavior is similar to the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) conversions applied when an lvalue is used as an rvalue, but also strips cv-qualifiers from class types in order to more closely model by-value argument passing. — end note] |
| template<bool B, class T = void> struct enable_if;                     | If B is true, the member typedef type shall equal T; otherwise, there shall be no member type.                                          |
| template<bool B, class T, class F> struct conditional;                 | If B is true, the member typedef type shall equal T. If B is false, the member typedef type shall equal F.                            |
| template<class... T> struct common_type;                               | Unless this trait is specialized (as specified in Note B, below), the member type is defined or omitted as specified in Note A, below. If it is omitted, there shall be no member type. Each type in the template parameter pack T shall be complete, cv void, or an array of unknown bound. |
| template<class, class, template<class> class, template<class> class> struct basic_common_reference; | Unless this trait is specialized (as specified in Note D, below), there shall be no member type.                                    |
| template<class... T> struct common_reference;                          | The member typedef-name type is defined or omitted as specified in Note C, below. Each type in the parameter pack T shall be complete or cv void. |
| template<class T>                                                     | If T is an enumeration type, the member typedef type names the underlying type of T (9.7.1); otherwise, there is no member type. Mandates: T is not an incomplete enumeration type. |
### Table 57: Other transformations (continued)

</tr>
</tbody>
</table>

1 [Note: A typical implementation would define `aligned_storage` as:]

```cpp
template<size_t Len, size_t Alignment>
struct aligned_storage {
  typedef struct {
    alignas(Alignment) unsigned char __data[Len];
  } type;
};
```

— end note]

2 In addition to being available via inclusion of the `<type_traits>` header, the templates `unwrap_reference`, `unwrap_ref_decay`, `unwrap_reference_t`, and `unwrap_ref_decay_t` are available when the header `<functional>` (20.14.1) is included.

3 Let:

- `CREF(A)` be `add_lvalue_reference_t<const remove_reference_t<A>>`,
- `XREF(A)` denote a unary alias template T such that T<T> denotes the same type as U with the addition of A’s cv and reference qualifiers, for a non-reference cv-unqualified type U.
- `COPYCV(FROM, TO)` be an alias for type TO with the addition of FROM’s top-level cv-qualifiers. [Example: `COPYCV(const int, volatile short)` is an alias for const volatile short. — end example]
- `COND-RES(X, Y)` be `decltype(false ? declval<X(&)()>()() : declval<Y(&)()>()())`.

Given types A and B, let X be `remove_reference_t<A>`, let Y be `remove_reference_t<B>`, and let `COMMON-REF(A, B)` be:

- If A and B are both lvalue reference types, `COMMON-REF(A, B)` is `COND-RES(COPYCV(X, Y) & & COPYCV(Y, X) &)` if that type exists and is a reference type.
- Otherwise, let C be `remove_reference_t<COMMON-REF(X, Y) & & C>`.
- Otherwise, let D be `COMMON-REF(const X&, Y&)`. If A is an rvalue reference and B is an lvalue reference and D is well-formed and `is_convertible_v<A, C> & & is_convertible_v<B, C>` is true, then `COMMON-REF(A, B)` is C.
- Otherwise, `COMMON-REF(A, B)` is ill-formed. If any of the types computed above is ill-formed, then `COMMON-REF(A, B)` is ill-formed.
4 Note A: For the common_type trait applied to a template parameter pack \( T \) of types, the member type shall be either defined or not present as follows:

\[\text{If } \text{sizeof...}(T) \text{ is zero, there shall be no member type.}\]

\[\text{If } \text{sizeof...}(T) \text{ is one, let } T_0 \text{ denote the sole type constituting the pack } T. \text{ The member typedef-name type shall denote the same type, if any, as } \text{common_type_t}<T_0, T_0>; \text{ otherwise there shall be no member type.}\]

\[\text{If } \text{sizeof...}(T) \text{ is two, let the first and second types constituting } T \text{ be denoted by } T_1 \text{ and } T_2, \text{ respectively, and let } D_1 \text{ and } D_2 \text{ denote the same types as } \text{decay_t}<T_1> \text{ and } \text{decay_t}<T_2>, \text{ respectively.}\]

\[\text{If } \text{is_same_v}<T_1, D_1> \text{ is false or } \text{is_same_v}<T_2, D_2> \text{ is false, let } C \text{ denote the same type, if any, as } \text{common_type_t}<D_1, D_2>.\]

\[\text{Otherwise, if } \text{decay_t}<\text{decltype}(false ? declval<D1>() : declval<D2>())> \text{ denotes a valid type, let } C \text{ denote that type.}\]

\[\text{Otherwise, if } \text{COND-RES}(\text{CREF}(D_1), \text{CREF}(D_2)) \text{ denotes a type, let } C \text{ denote the type } \text{decay_t}<\text{COND-RES}(\text{CREF}(D_1), \text{CREF}(D_2))>.\]

\[\text{In either case, the member typedef-name type shall denote the same type, if any, as } C. \text{ Otherwise, there shall be no member type.}\]

\[\text{If } \text{sizeof...}(T) \text{ is greater than two, let } T_1, T_2, \text{ and } R, \text{ respectively, denote the first, second, and (pack of) remaining types constituting } T. \text{ Let } C \text{ denote the same type, if any, as } \text{common_type_t}<T_1, T_2>. \text{ If there is such a type } C, \text{ the member typedef-name type shall denote the same type, if any, as } \text{common_type_t}<C, R, \ldots>. \text{ Otherwise, there shall be no member type.}\]

5 Note B: Notwithstanding the provisions of 20.15.2, and pursuant to 16.5.4.2.1, a program may specialize \text{common_type} for types \( T_1 \) and \( T_2 \) such that \text{is_same_v}<T_1, \text{decay_t}<T_1>> \text{ and } \text{is_same_v}<T_2, \text{decay_t}<T_2>> \text{ are each true}. [Note: Such specializations are needed when only explicit conversions are desired between the template arguments. — end note] Such a specialization need not have a member named type, but if it does, that member shall be a \text{typedef-name} for an accessible and unambiguous cv-unqualified non-reference type \( C \) to which each of the types \( T_1 \) and \( T_2 \) is explicitly convertible. Moreover, \text{common_type_t}<T_1, T_2> shall denote the same type, if any, as \text{common_type_t}<T_1, T_2, T_1>. No diagnostic is required for a violation of this Note’s rules.

6 Note C: For the common_reference trait applied to a parameter pack \( T \) of types, the member type shall be either defined or not present as follows:

\[\text{If } \text{sizeof...}(T) \text{ is zero, there shall be no member type.}\]

\[\text{Otherwise, if } \text{sizeof...}(T) \text{ is one, let } T_0 \text{ denote the sole type in the pack } T. \text{ The member typedef type shall denote the same type as } T_0.\]

\[\text{Otherwise, if } \text{sizeof...}(T) \text{ is two, let } T_1 \text{ and } T_2 \text{ denote the two types in the pack } T. \text{ Then}\]

\[\text{If } T_1 \text{ and } T_2 \text{ are reference types and } \text{COMMON-REF}(T_1, T_2) \text{ is well-formed, then the member typedef type denotes that type.}\]

\[\text{Otherwise, if } \text{basic_common_reference<remove_cvref_t<T1>>, remove_cvref_t<T2>>, XREF(T1), XREF(T2)>>::type \text{ is well-formed, then the member typedef type denotes that type.}\]

\[\text{Otherwise, if } \text{COND-RES}(T_1, T_2) \text{ is well-formed, then the member typedef type denotes that type.}\]

\[\text{Otherwise, if } \text{common_type_t}<T_1, T_2> \text{ is well-formed, then the member typedef type denotes that type.}\]

\[\text{Otherwise, there shall be no member type.}\]

\[\text{Otherwise, if } \text{sizeof...}(T) \text{ is greater than two, let } T_1, T_2, \text{ and } \text{Rest}, \text{ respectively, denote the first, second, and (pack of) remaining types comprising } T. \text{ Let } C \text{ be the type } \text{common_reference_t}<T_1, T_2>. \text{ Then:}\]

\[\text{If there is such a type } C, \text{ the member typedef type shall denote the same type, if any, as } \text{common_reference_t}<C, \text{Rest}>.\]

\[\text{Otherwise, there shall be no member type.}\]

7 Note D: Notwithstanding the provisions of 20.15.2, and pursuant to 16.5.4.2.1, a program may partially specialize \text{basic_common_reference<T, U, TQual, UQual>} for types \( T \) and \( U \) such that \text{is_same_v<T, decay_t}<T>> \text{ and } \text{is_same_v<U, decay_t}<U>> \text{ are each true}. [Note: Such specializations can be used to influence the result of
common_reference, and are needed when only explicit conversions are desired between the template arguments.

— end note] Such a specialization need not have a member named type, but if it does, that member shall be a typedef-name for an accessible and unambiguous type C to which each of the types TQual<T> and UQual<U> is convertible. Moreover, basic_common_reference<T, U, TQual, UQual>::type shall denote the same type, if any, as does basic_common_reference<U, T, UQual, TQual>::type. No diagnostic is required for a violation of these rules.

8 [Example: Given these definitions:

```cpp
using PF1 = bool (&)();
using PF2 = short (*)(long);

struct S {
  operator PF2() const;
  double operator() (char, int&);
  void fn(long) const;
  char data;
};

using PMF = void (S::*)(long) const;
using PMD = char S::*;
```

the following assertions will hold:

- static_assert(is_same_v<invoke_result_t<S, int>, short>);
- static_assert(is_same_v<invoke_result_t<S&, unsigned char, int&>, double>);
- static_assert(is_same_v<invoke_result_t<PF1>, bool>);
- static_assert(is_same_v<invoke_result_t<PMF, unique_ptr<S>, int>, void>);
- static_assert(is_same_v<invoke_result_t<PMD, S>, char&&>);
- static_assert(is_same_v<invoke_result_t<PMD, const S*>, const char&>);

— end example]

20.15.8 Logical operator traits [meta.logical]

1 This subclause describes type traits for applying logical operators to other type traits.

```cpp
template<class... B> struct conjunction : see below { };  
```

2 The class template conjunction forms the logical conjunction of its template type arguments.

3 For a specialization conjunction<B_1, ..., B_N>, if there is a template type argument B_i for which bool(B_i::value) is false, then instantiating conjunction<B_1, ..., B_N>::value does not require the instantiation of B_j::value for j > i. [Note: This is analogous to the short-circuiting behavior of the built-in operator &&. — end note]

4 Every template type argument for which B_i::value is instantiated shall be usable as a base class and shall have a member value which is convertible to bool, is not hidden, and is unambiguously available in the type.

5 The specialization conjunction<B_1, ..., B_N> has a public and unambiguous base that is either

5.1 — the first type B_1 in the list true_type, B_1, ..., B_N for which bool(B_i::value) is false, or

5.2 — if there is no such B_i, the last type in the list.

[Note: This means a specialization of conjunction does not necessarily inherit from either true_type or false_type. — end note]

6 The member names of the base class, other than conjunction and operator=, shall not be hidden and shall be unambiguously available in conjunction.

```cpp
template<class... B> struct disjunction : see below { };  
```

7 The class template disjunction forms the logical disjunction of its template type arguments.

8 For a specialization disjunction<B_1, ..., B_N>, if there is a template type argument B_i for which bool(B_i::value) is true, then instantiating disjunction<B_1, ..., B_N>::value does not require the instantiation of B_j::value for j > i. [Note: This is analogous to the short-circuiting behavior of the built-in operator ||. — end note]

9 Every template type argument for which B_i::value is instantiated shall be usable as a base class and shall have a member value which is convertible to bool, is not hidden, and is unambiguously available in the type.

10 The specialization disjunction<B_1, ..., B_N> has a public and unambiguous base that is either

§ 20.15.8 694
— the first type \(B_i\) in the list \(\text{false}_\text{type}, B_1, \ldots, B_N\) for which \(\text{bool}(B_i::\text{value})\) is true, or
— if there is no such \(B_i\), the last type in the list.

[Note: This means a specialization of \(\text{disjunction}\) does not necessarily inherit from either \(\text{true}_\text{type}\) or \(\text{false}_\text{type}. \) — end note]

The member names of the base class, other than \(\text{disjunction}\) and \(\text{operator=}\), shall not be hidden and shall be unambiguously available in \(\text{disjunction}\).

\[
\text{template<class B> struct negation : see below { }};
\]

The class template \(\text{negation}\) forms the logical negation of its template type argument. The type \(\text{negation}\langle B\rangle\) is a \(\text{Cpp17UnaryTypeTrait}\) with a base characteristic of \(\text{bool}_\text{constant}!<\text{bool}(B::\text{value})>\).

### 20.15.9 Member relationships

[meta.member]

\[
\text{template<class S, class M>}
\]

\[
\text{constexpr bool is_pointer_interconvertible_with_class}(M S::*m) \text{ noexcept};
\]

1. \textit{Mandates:} \(S\) is a complete type.
2. \textit{Returns:} \(true\) if and only if \(S\) is a standard-layout type, \(M\) is an object type, \(m\) is not null, and each object \(s\) of type \(S\) is pointer-interconvertible (6.8.2) with its subobject \(s.*m\).

\[
\text{template<class S1, class S2, class M1, class M2>}
\]

\[
\text{constexpr bool is_corresponding_member}(M1 S1::*m1, M2 S2::*m2) \text{ noexcept};
\]

3. \textit{Mandates:} \(S1\) and \(S2\) are complete types.
4. \textit{Returns:} \(true\) if and only if \(S1\) and \(S2\) are standard-layout types, \(M1\) and \(M2\) are object types, \(m1\) and \(m2\) are not null, and \(m1\) and \(m2\) point to corresponding members of the common initial sequence (11.4) of \(S1\) and \(S2\).

[Note: The type of a pointer-to-member expression \&C::b is not always a pointer to member of \(C\), leading to potentially surprising results when using these functions in conjunction with inheritance. [Example:

```cpp
struct A { int a; }; // a standard-layout class
struct B { int b; }; // a standard-layout class
struct C: public A, public B { }; // not a standard-layout class

static_assert( is_pointer_interconvertible_with_class( \&C::b ) ); // Succeeds because, despite its appearance, \&C::b has type
// "pointer to member of \(B\) of type int".
static_assert( is_pointer_interconvertible_with_class\langle\&C::b\rangle( \&C::b ) ); // Forces the use of class \(C\), and fails.

static_assert( is_corresponding_member( \&C::a, \&C::b ) ); // Succeeds because, despite its appearance, \&C::a and \&C::b have types
// "pointer to member of \(A\) of type int" and
// "pointer to member of \(B\) of type int", respectively.
static_assert( is_corresponding_member\langle C, \&C::a, \&C::b \rangle( \&C::a, \&C::b ) ); // Forces the use of class \(C\), and fails.
```

— end example] — end note]

### 20.15.10 Constant evaluation context

[meta.const.eval]

\[
\text{constexpr bool is_constant_evaluated()} \text{ noexcept;}
\]

1. \textit{Returns:} \(true\) if and only if evaluation of the call occurs within the evaluation of an expression or conversion that is manifestly constant-evaluated (7.7).
2. \textit{[Example:]}

```cpp
constexpr void f(unsigned char *p, int n) {
  if (std::is_constant_evaluated()) {
    // should not be a constexpr if statement
    for (int k = 0; k<n; ++k) p[k] = 0;
  } else {
    memset(p, 0, n); // not a core constant expression
  }
}
```

§ 20.15.10 695
20.16 Compile-time rational arithmetic

20.16.1 In general

Subclause 20.16 describes the ratio library. It provides a class template `ratio` which exactly represents any finite rational number with a numerator and denominator representable by compile-time constants of type `intmax_t`.

Throughout subclause 20.16, the names of template parameters are used to express type requirements. If a template parameter is named `R1` or `R2`, and the template argument is not a specialization of the `ratio` template, the program is ill-formed.

20.16.2 Header `<ratio>` synopsis

```cpp
namespace std {
    // 20.16.3, class template ratio
    template<intmax_t N, intmax_t D = 1> class ratio;
    // 20.16.4, ratio arithmetic
    template<class R1, class R2> using ratio_add = see below;
    template<class R1, class R2> using ratio_subtract = see below;
    template<class R1, class R2> using ratio_multiply = see below;
    template<class R1, class R2> using ratio_divide = see below;
    // 20.16.5, ratio comparison
    template<class R1, class R2> struct ratio_equal;
    template<class R1, class R2> struct ratio_not_equal;
    template<class R1, class R2> struct ratio_less;
    template<class R1, class R2> struct ratio_less_equal;
    template<class R1, class R2> struct ratio_greater;
    template<class R1, class R2> struct ratio_greater_equal;
    template<class R1, class R2>
        inline constexpr bool ratio_equal_v = ratio_equal<R1, R2>::value;
    template<class R1, class R2>
        inline constexpr bool ratio_not_equal_v = ratio_not_equal<R1, R2>::value;
    template<class R1, class R2>
        inline constexpr bool ratio_less_v = ratio_less<R1, R2>::value;
    template<class R1, class R2>
        inline constexpr bool ratio_less_equal_v = ratio_less_equal<R1, R2>::value;
    template<class R1, class R2>
        inline constexpr bool ratio_greater_v = ratio_greater<R1, R2>::value;
    template<class R1, class R2>
        inline constexpr bool ratio_greater_equal_v = ratio_greater_equal<R1, R2>::value;
    // 20.16.6, convenience SI typedefs
    using yocto = ratio<1, 1'000'000'000'000'000'000'000'000'000'000';
    using zepto = ratio<1, 1'000'000'000'000'000'000'000'000'000'000';
    using atto = ratio<1, 1'000'000'000'000'000'000';
    using femto = ratio<1, 1'000'000'000';
    using pico = ratio<1, 1'000'000';
    using nano = ratio<1, 1'000';
    using micro = ratio<1, 1';
    using milli = ratio<1, 100';
    using centi = ratio<1, 10';
    using deci = ratio<1, 10';
    using hecto = ratio<1, 100';
    using kilo = ratio<1, 1000';
    using mega = ratio<1, 10000';
    using giga = ratio<1, 100000';
    using tera = ratio<1, 1000000';
    using peta = ratio<1, 10000000';
    using exa = ratio<1, 100000000';
    using zetta = ratio<1, 1000000000';
```

§ 20.16.2
using yotta = ratio<1'000'000'000'000'000'000'000'000, 1>;  // see below
}

20.16.3 Class template ratio

namespace std {
    template<intmax_t N, intmax_t D = 1> class ratio {
    public:
        static constexpr intmax_t num;
        static constexpr intmax_t den;
        using type = ratio<num, den>;
    };
}

1 If the template argument D is zero or the absolute values of either of the template arguments N and D is not representable by type intmax_t, the program is ill-formed. [Note: These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. This excludes the most negative value. — end note]

2 The static data members num and den shall have the following values, where gcd represents the greatest common divisor of the absolute values of N and D:

(2.1) num shall have the value sign(N) * sign(D) * abs(N) / gcd.
(2.2) den shall have the value abs(D) / gcd.

20.16.4 Arithmetic on ratios

1 Each of the alias templates ratio_add, ratio_subtract, ratio_multiply, and ratio_divide denotes the result of an arithmetic computation on two ratios R1 and R2. With X and Y computed (in the absence of arithmetic overflow) as specified by Table 58, each alias denotes a ratio<U, V> such that U is the same as ratio<X, Y>::num and V is the same as ratio<X, Y>::den.

2 If it is not possible to represent U or V with intmax_t, the program is ill-formed. Otherwise, an implementation should yield correct values of U and V. If it is not possible to represent X or Y with intmax_t, the program is ill-formed unless the implementation yields correct values of U and V.

Table 58: Expressions used to perform ratio arithmetic

<table>
<thead>
<tr>
<th>Type</th>
<th>Value of X</th>
<th>Value of Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>ratio_add&lt;R1, R2&gt;</td>
<td>R1::num * R2::den + R1::den * R2::den</td>
<td>R2::num * R1::den</td>
</tr>
<tr>
<td>ratio_subtract&lt;R1, R2&gt;</td>
<td>R1::num * R2::den - R1::den * R2::den</td>
<td>R2::num * R1::den</td>
</tr>
<tr>
<td>ratio_multiply&lt;R1, R2&gt;</td>
<td>R1::num * R2::num</td>
<td>R1::den * R2::den</td>
</tr>
<tr>
<td>ratio_divide&lt;R1, R2&gt;</td>
<td>R1::num * R2::den</td>
<td>R1::den * R2::num</td>
</tr>
</tbody>
</table>

3 [Example:

static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::num == 1, "1/3+1/6 == 1/2");
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::num == 1, "1/3*3/2 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::den == 2, "1/3*3/2 == 1/2");

// The following cases may cause the program to be ill-formed under some implementations
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::num == 2, "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::den == INT_MAX, "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::num == 1, "1/MAX * MAX/2 == 1/2");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::den == 2, "1/MAX * MAX/2 == 1/2");

—end example]
20.16.5 Comparison of ratios

```cpp
template<class R1, class R2>
struct ratio_equal : bool_constant<R1::num == R2::num && R1::den == R2::den> { };

template<class R1, class R2>
struct ratio_not_equal : bool_constant!<ratio_equal_v<R1, R2>> { };

template<class R1, class R2>
struct ratio_less : bool_constant<see below> { };

If R1::num \times R2::den is less than R2::num \times R1::den, ratio_less<R1, R2> shall be derived from bool_constant<true>; otherwise it shall be derived from bool_constant<false>. Implementations may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program is ill-formed.

template<class R1, class R2>
struct ratio_less_equal : bool_constant!<ratio_less_v<R2, R1>> { };

template<class R1, class R2>
struct ratio_greater : bool_constant<ratio_less_v<R2, R1>> { };

template<class R1, class R2>
struct ratio_greater_equal : bool_constant!<ratio_less_v<R1, R2>> { };
```

20.16.6 SI types for ratio

```cpp
1 For each of the typedef-names yocto, zepto, zetta, and yotta, if both of the constants used in its specification are representable by intmax_t, the typedef is defined; if either of the constants is not representable by intmax_t, the typedef is not defined.
```

20.17 Class type_index

20.17.1 Header <typeindex> synopsis

```cpp
#include <compare> // see 17.11.1

namespace std {
    class type_index;
    template<class T> struct hash;
    template<> struct hash<type_index>;
}
```

20.17.2 type_index overview

```cpp
namespace std {
    class type_index {
        public:
            type_index(const type_info& rhs) noexcept;
            bool operator==(const type_index& rhs) const noexcept;
            bool operator< (const type_index& rhs) const noexcept;
            bool operator> (const type_index& rhs) const noexcept;
            bool operator<=(const type_index& rhs) const noexcept;
            bool operator>=(const type_index& rhs) const noexcept;
            strong_ordering operator<=>(const type_index& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;

        private:
            const type_info* target; // exposition only
            // Note that the use of a pointer here, rather than a reference,
            // means that the default copy/move constructor and assignment
            // operators will be provided and work as expected.
    };
}
```

The class type_index provides a simple wrapper for type_info which can be used as an index type in associative containers (22.4) and in unordered associative containers (22.5).
20.17.3  type_index members

```cpp
type_index(const type_info& rhs) noexcept;
```

**Effects:** Constructs a type_index object, the equivalent of target = &rhs.

```cpp
bool operator==(const type_index& rhs) const noexcept;
```

**Returns:** *target == *rhs.target.

```cpp
bool operator<(const type_index& rhs) const noexcept;
```

**Returns:** target->before(*rhs.target).

```cpp
bool operator>(const type_index& rhs) const noexcept;
```

**Returns:** rhs.target->before(*target).

```cpp
bool operator<=(const type_index& rhs) const noexcept;
```

**Returns:** !rhs.target->before(*target).

```cpp
bool operator>=(const type_index& rhs) const noexcept;
```

**Returns:** !target->before(*rhs.target).

```cpp
strong_ordering operator<=>(const type_index& rhs) const noexcept;
```

**Effects:** Equivalent to:
- if (*target == *rhs.target) return strong_ordering::equal;
- if (target->before(*rhs.target)) return strong_ordering::less;
- return strong_ordering::greater;

```cpp
size_t hash_code() const noexcept;
```

**Returns:** target->hash_code().

```cpp
const char* name() const noexcept;
```

**Returns:** target->name().

20.17.4  Hash support

```cpp
template<> struct hash<type_index>;
```

For an object index of type type_index, hash<type_index>(index) shall evaluate to the same result as index.hash_code().

20.18  Execution policies

20.18.1  In general

Subclause 20.18 describes classes that are execution policy types. An object of an execution policy type indicates the kinds of parallelism allowed in the execution of an algorithm and expresses the consequent requirements on the element access functions. [Example:
- using namespace std;
- vector<int> v = /* ... */;

  // standard sequential sort
  sort(v.begin(), v.end());

  // explicitly sequential sort
  sort(execution::seq, v.begin(), v.end());

  // permitting parallel execution
  sort(execution::par, v.begin(), v.end());

  // permitting vectorization as well
  sort(execution::par_unseq, v.begin(), v.end());
```
Note: Because different parallel architectures may require idiosyncratic parameters for efficient execution, implementations may provide additional execution policies to those described in this standard as extensions.

20.18.2 Header `<execution>` synopsis

```cpp
namespace std {
    // 20.18.3, execution policy type trait
    template<class T> struct is_execution_policy;
    template<class T> inline constexpr bool is_execution_policy_v = is_execution_policy<T>::value;
}
namespace std::execution {
    // 20.18.4, sequenced execution policy
    class sequenced_policy;
    // 20.18.5, parallel execution policy
    class parallel_policy;
    // 20.18.6, parallel and unsequenced execution policy
    class parallel_unsequenced_policy;
    // 20.18.7, unsequenced execution policy
    class unsequenced_policy;
    // 20.18.8, execution policy objects
    inline constexpr sequenced_policy seq{ unspecified };
    inline constexpr parallel_policy par{ unspecified };
    inline constexpr parallel_unsequenced_policy par_unseq{ unspecified };
    inline constexpr unsequenced_policy unseq{ unspecified };
}
```

20.18.3 Execution policy type trait

```
template<class T> struct is_execution_policy { see below };
```

1. `is_execution_policy` can be used to detect execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.

2. `is_execution_policy<T>` is a `Cpp17UnaryTypeTrait` with a base characteristic of `true_type` if `T` is the type of a standard or implementation-defined execution policy, otherwise `false_type`.

[Note: This provision reserves the privilege of creating non-standard execution policies to the library implementation. — end note]

3. The behavior of a program that adds specializations for `is_execution_policy` is undefined.

20.18.4 Sequenced execution policy

```
class execution::sequenced_policy { unspecified };
```

1. The class `execution::sequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be parallelized.

2. During the execution of a parallel algorithm with the `execution::sequenced_policy` policy, if the invocation of an element access function exits via an uncaught exception, `terminate()` is called.

20.18.5 Parallel execution policy

```
class execution::parallel_policy { unspecified };
```

1. The class `execution::parallel_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized.

2. During the execution of a parallel algorithm with the `execution::parallel_policy` policy, if the invocation of an element access function exits via an uncaught exception, `terminate()` is called.
20.18.6 Parallel and unsequenced execution policy

```cpp
class execution::parallel_unsequenced_policy { unspecified; }
```

1. The class `execution::parallel_unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized and vectorized.

2. During the execution of a parallel algorithm with the `execution::parallel_unsequenced_policy` policy, if the invocation of an element access function exits via an uncaught exception, `terminate()` is called.

20.18.7 Unsequenced execution policy

```cpp
class execution::unsequenced_policy { unspecified; }
```

1. The class `unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be vectorized, e.g., executed on a single thread using instructions that operate on multiple data items.

2. During the execution of a parallel algorithm with the `execution::unsequenced_policy` policy, if the invocation of an element access function exits via an uncaught exception, `terminate()` is called.

20.18.8 Execution policy objects

```cpp
inline constexpr execution::sequenced_policy execution::seq{ unspecified; }
inline constexpr execution::parallel_policy execution::par{ unspecified; }
inline constexpr execution::parallel_unsequenced_policy execution::par_unseq{ unspecified; }
inline constexpr execution::unsequenced_policy execution::unseq{ unspecified; }
```

1. The header `<execution>` declares global objects associated with each type of execution policy.

20.19 Primitive numeric conversions

20.19.1 Header `<charconv>` synopsis

```cpp
namespace std {

    // floating-point format for primitive numerical conversion
    enum class chars_format {
        scientific = unspecified,
        fixed = unspecified,
        hex = unspecified,
        general = fixed | scientific
    };

    // primitive numerical output conversion
    struct to_chars_result {
        char* ptr;
        errc ec;
        friend bool operator==(const to_chars_result& l, const to_chars_result& r) = default;
    };

    to_chars_result to_chars(char* first, char* last, see below value, int base = 10);
    to_chars_result to_chars(char* first, char* last, bool value, int base = 10) = delete;
    to_chars_result to_chars(char* first, char* last, float value);
    to_chars_result to_chars(char* first, char* last, double value);
    to_chars_result to_chars(char* first, char* last, long double value);
    to_chars_result to_chars(char* first, char* last, float value, chars_format fmt);
    to_chars_result to_chars(char* first, char* last, double value, chars_format fmt);
    to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt);
    to_chars_result to_chars(char* first, char* last, float value, chars_format fmt, int precision);
    to_chars_result to_chars(char* first, char* last, double value, chars_format fmt, int precision);
    to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt, int precision);
```

§ 20.19.1
// 20.19.3, primitive numerical input conversion
struct from_chars_result {
    const char* ptr;
    errc ec;
    friend bool operator==(const from_chars_result&, const from_chars_result&) = default;
};

from_chars_result from_chars(const char* first, const char* last,
    see below& value, int base = 10);

from_chars_result from_chars(const char* first, const char* last, float& value,
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value,
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value,
    chars_format fmt = chars_format::general);
}

1 The type chars_format is a bitmask type (16.4.2.2.4) with elements scientific, fixed, and hex.
2 The types to_chars_result and from_chars_result have the data members and special members specified above. They have no base classes or members other than those specified.

20.19.2 Primitive numeric output conversion

All functions named to_chars convert value into a character string by successively filling the range [first, last), where [first, last) is required to be a valid range. If the member ec of the return value is such that the value is equal to the value of a value-initialized errc, the conversion was successful and the member ptr is the one-past-the-end pointer of the characters written. Otherwise, the member ec has the value errc::value-too-large, the member ptr has the value last, and the contents of the range [first, last) are unspecified.

The functions that take a floating-point value but not a precision parameter ensure that the string representation consists of the smallest number of characters such that there is at least one digit before the radix point (if present) and parsing the representation using the corresponding from_chars function recovers value exactly. [Note: This guarantee applies only if to_chars and from_chars are executed on the same implementation. — end note] If there are several such representations, the representation with the smallest difference from the floating-point argument value is chosen, resolving any remaining ties using rounding according to round_to_nearest (17.3.4.1).

The functions taking a chars_format parameter determine the conversion specifier for printf as follows: The conversion specifier is f if fmt is chars_format::fixed, e if fmt is chars_format::scientific, a (without leading "0x" in the result) if fmt is chars_format::hex, and g if fmt is chars_format::general.

to_chars_result to_chars(char* first, char* last, see below value, int base = 10);

4 Preconditions: base has a value between 2 and 36 (inclusive).
5 Effects: The value of value is converted to a string of digits in the given base (with no redundant leading zeroes). Digits in the range 10..35 (inclusive) are represented as lowercase characters a..z. If value is less than zero, the representation starts with ' - '.
6 Throws: Nothing.
7 Remarks: The implementation shall provide overloads for all signed and unsigned integer types and char as the type of the parameter value.

to_chars_result to_chars(char* first, char* last, float value);
to_chars_result to_chars(char* first, char* last, double value);
to_chars_result to_chars(char* first, char* last, long double value);
8 Effects: value is converted to a string in the style of printf in the "C" locale. The conversion specifier is f or e, chosen according to the requirement for a shortest representation (see above); a tie is resolved in favor of f.
9 Throws: Nothing.

to_chars_result to_chars(char* first, char* last, float value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt);

**Preconditions:** fmt has the value of one of the enumerators of chars_format.

**Effects:** value is converted to a string in the style of printf in the "C" locale.

**Throws:** Nothing.

to_chars_result to_chars(char* first, char* last, float value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt, int precision);

**Preconditions:** fmt has the value of one of the enumerators of chars_format.

**Effects:** value is converted to a string in the style of printf in the "C" locale with the given precision.

**Throws:** Nothing.

SEE ALSO: ISO C 7.21.6.1

### 20.19.3 Primitive numeric input conversion  

All functions named from_chars analyze the string (first, last) for a pattern, where (first, last) is required to be a valid range. If no characters match the pattern, value is unmodified, the member ptr of the return value is first and the member ec is equal to errc::invalid_argument. [Note: If the pattern allows for an optional sign, but the string has no digit characters following the sign, no characters match the pattern. — end note] Otherwise, the characters matching the pattern are interpreted as a representation of a value of the type of value. The member ptr of the return value points to the first character not matching the pattern, or has the value last if all characters match. If the parsed value is not in the range representable by the type of value, value is unmodified and the member ec of the return value is equal to errc::result_out_of_range. Otherwise, value is set to the parsed value, after rounding according to round_to_nearest (17.3.4.1), and the member ec is value-initialized.

from_chars_result from_chars(const char* first, const char* last, int base = 10);

**Preconditions:** base has a value between 2 and 36 (inclusive).

**Effects:** The pattern is the expected form of the subject sequence in the "C" locale for the given nonzero base, as described for strtol, except that no "0x" or "0X" prefix shall appear if the value of base is 16, and except that ‘-' is the only sign that may appear, and only if value has a signed type.

**Throws:** Nothing.

**Remarks:** The implementation shall provide overloads for all signed and unsigned integer types and char as the referenced type of the parameter value.

from_chars_result from_chars(const char* first, const char* last, float& value, chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value, chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value, chars_format fmt = chars_format::general);

**Preconditions:** fmt has the value of one of the enumerators of chars_format.

**Effects:** The pattern is the expected form of the subject sequence in the "C" locale, as described for strtod, except that

- the sign ‘+’ may only appear in the exponent part;
- if fmt has chars_format::scientific set but not chars_format::fixed, the otherwise optional exponent part shall appear;
- if fmt has chars_format::fixed set but not chars_format::scientific, the optional exponent part shall not appear; and
- if fmt is chars_format::hex, the prefix "0x" or "0X" is assumed. [Example: The string 0x123 is parsed to have the value 0 with remaining characters x123. — end example]
In any case, the resulting value is one of at most two floating-point values closest to the value of the string matching the pattern.

Throws: Nothing.

format_args_t<type_identity_t<Out>, wchar_t> args);

template<class Out> struct format_to_n_result {
    Out out;
    iter_difference_t<Out> size;
};

§ 20.20.1
The class template `format_to_n_result` has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

20.20.2 Format string

20.20.2.1 In general

A format string for arguments `args` is a (possibly empty) sequence of replacement fields, escape sequences, and characters other than `{` and `}`. Let `charT` be the character type of the format string. Each character that is not part of a replacement field or an escape sequence is copied unchanged to the output. An escape sequence is one of `{{` or `}}`. It is replaced with `{` or `}`, respectively, in the output. The syntax of replacement fields is as follows:
replacement-field:
   { arg-id_opt format-specifier_opt }

arg-id:
   0
   positive-integer
positive-integer:
   nonzero-digit
   positive-integer digit
nonnegative-integer:
   digit
   nonnegative-integer digit
nonzero-digit: one of
   1 2 3 4 5 6 7 8 9
digit: one of
   0 1 2 3 4 5 6 7 8 9
format-specifier:
   : format-spec
format-spec:
   as specified by the formatter specialization for the argument type

2 The arg-id field specifies the index of the argument in args whose value is to be formatted and inserted into the output instead of the replacement field. If there is no argument with the index arg-id in args, the string is not a format string for args. The optional format-specifier field explicitly specifies a format for the replacement value.

3 [Example:
   string s = format("{0}"-{", "}, 8); // value of s is "8-"
   — end example]

4 If all arg-ids in a format string are omitted (including those in the format-spec, as interpreted by the corresponding formatter specialization), argument indices 0, 1, 2, … will automatically be used in that order. If some arg-ids are omitted and some are present, the string is not a format string. [Note: A format string cannot contain a mixture of automatic and manual indexing. — end note] [Example:
   string s0 = format("{1}" to {}, "a", "b"); // OK, automatic indexing
   string s1 = format("{0}" to {0}, "a", "b"); // OK, manual indexing
   string s2 = format("{0}" to {}", "a", "b"); // not a format string (mixing automatic and manual indexing),
   // throws format_error
   string s3 = format("{1}" to {1}"", "a", "b"); // not a format string (mixing automatic and manual indexing),
   // throws format_error
   — end example]

5 The format-spec field contains format specifications that define how the value should be presented. Each type can define its own interpretation of the format-spec field. If format-spec does not conform to the format specifications for the argument type referred to by arg-id, the string is not a format string for args. [Example:
   (5.1) For arithmetic, pointer, and string types the format-spec is interpreted as a std-format-spec as described in (20.20.2.2).
   (5.2) For chrono types the format-spec is interpreted as a chrono-format-spec as described in (27.12).
   (5.3) For user-defined formatter specializations, the behavior of the parse member function determines how the format-spec is interpreted.
   — end example]

20.20.2.2 Standard format specifiers

[format.string.std]

1 Each formatter specializations described in 20.20.5.2 for fundamental and string types interprets format-spec as a std-format-spec. [Note: The format specification can be used to specify such details as field width, alignment, padding, and decimal precision. Some of the formatting options are only supported for arithmetic types. — end note] The syntax of format specifications is as follows:

std-format-spec:
   fill-and-align_opt sign_opt #_opt 0_opt width_opt precision_opt L_opt type_opt
fill-and-align:
  fill_opt align

fill:
  any character other than { or }

align: one of
  < > ~

sign: one of
  + - space

width:
  positive-integer
  { arg-id_opt }

precision:
  . nonnegative-integer
  . { arg-id_opt }

type: one of
  a A b B c d e E f F g G o p s x X

2 [Note: The fill character can be any character other than { or }. The presence of a fill character is signaled by the character following it, which must be one of the alignment options. If the second character of std-format-spec is not a valid alignment option, then it is assumed that both the fill character and the alignment option are absent. — end note]

3 The align specifier applies to all argument types. The meaning of the various alignment options is as specified in Table 59. [Example:

```c
char c = 120;
string s0 = format("{:6}", 42); // value of s0 is " 42"
string s1 = format("{:6}", 'x'); // value of s1 is "x "
string s2 = format("{:<6}", 'x'); // value of s2 is "******"
string s3 = format("{:>6}", 'x'); // value of s3 is "*****x"
string s4 = format("{:*<6}", 'x'); // value of s4 is "x*****"
string s5 = format("{:*^6}", 'x'); // value of s5 is "**x***"
string s6 = format("{:6d}", c); // value of s6 is " 120"
string s7 = format("{:6}", true); // value of s6 is "true "
```
— end example] [Note: Unless a minimum field width is defined, the field width is determined by the size of the content and the alignment option has no effect. — end note]

Table 59: Meaning of align options  [tab:format.align]

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>Forces the field to be aligned to the start of the available space. This is the default for non-arithmetic types, charT, and bool, unless an integer presentation type is specified.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Forces the field to be aligned to the end of the available space. This is the default for arithmetic types other than charT and bool or when an integer presentation type is specified.</td>
</tr>
<tr>
<td>~</td>
<td>Forces the field to be centered within the available space by inserting ( \lfloor \frac{n}{2} \rfloor ) characters before and ( \lceil \frac{n}{2} \rceil ) characters after the value, where ( n ) is the total number of fill characters to insert.</td>
</tr>
</tbody>
</table>

4 The sign option is only valid for arithmetic types other than charT and bool or when an integer presentation type is specified. The meaning of the various options is as specified in Table 60.

5 The sign option applies to floating-point infinity and NaN. [Example:

```c
double inf = numeric_limits<double>::infinity();
double nan = numeric_limits<double>::quiet_NaN();
string s0 = format("{0},{0:+},{0:-},{0: }", 1); // value of s0 is "1,+1,1, 1"
string s1 = format("{0},{0:+},{0:-},{0: }", -1); // value of s1 is "+-1,-1,-1,1"
string s2 = format("{0},{0:+},{0:-},{0: }", inf); // value of s2 is "inf,+inf,inf , inf"
string s3 = format("{0},{0:+},{0:-},{0: }", nan); // value of s3 is "nan,+nan,nan, nan"
```
— end example]

6 The # option causes the alternate form to be used for the conversion. This option is valid for arithmetic types other than charT and bool or when an integer presentation type is specified, and not otherwise. For integral types, the
Table 60: Meaning of sign options  [tab:format.sign]

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Indicates that a sign should be used for both non-negative and negative numbers. The + sign is inserted before the output of to_chars for non-negative numbers other than negative zero. [Note: For negative numbers and negative zero the output of to_chars will already contain the sign so no additional transformation is performed. — end note]</td>
</tr>
<tr>
<td>-</td>
<td>Indicates that a sign should be used for negative numbers and negative zero only (this is the default behavior).</td>
</tr>
<tr>
<td>space</td>
<td>Indicates that a leading space should be used for non-negative numbers other than negative zero, and a minus sign for negative numbers and negative zero.</td>
</tr>
</tbody>
</table>

The alternate form inserts the base prefix (if any) specified in Table 62 into the output after the sign character (possibly space) if there is one, or before the output of to_chars otherwise. For floating-point types, the alternate form causes the result of the conversion of finite values to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for g and G conversions, trailing zeros are not removed from the result.

7 If { arg-id-opt } is used in a width or precision, the value of the corresponding formatting argument is used in its place. If the corresponding formatting argument is not of integral type, or its value is negative for precision or non-positive for width, an exception of type format_error is thrown.

8 The positive-integer in width is a decimal integer defining the minimum field width. If width is not specified, there is no minimum field width, and the field width is determined based on the content of the field.

9 The width of a string is defined as the estimated number of column positions appropriate for displaying it in a terminal. [Note: This is similar to the semantics of the POSIX wcswidth function. — end note]

10 For the purposes of width computation, a string is assumed to be in a locale-independent, implementation-defined encoding. Implementations should use a Unicode encoding on platforms capable of displaying Unicode text in a terminal. [Note: This is the case for Windows-based and many POSIX-based operating systems. — end note]

11 For a string in a Unicode encoding, implementations should estimate the width of a string as the sum of estimated widths of the first code points in its extended grapheme clusters. The extended grapheme clusters of a string are defined by UAX #29. The estimated width of the following code points is 2:

- U+1100-U+115F
- U+2329-U+232A
- U+2E80-U+303E
- U+3040-U+A4CF
- U+AC00-U+D7A3
- U+F900-U+FAFF
- U+FE10-U+FE19
- U+FE30-U+FE6F
- U+FF00-U+FF60
- U+FFE0-U+FFE6
- U+1F300-U+1F64F
- U+1F900-U+1F9FF
- U+20000-U+2FFFD
- U+30000-U+3FFFD

The estimated width of other code points is 1.

12 For a string in a non-Unicode encoding, the width of a string is unspecified.

13 A zero (0) character preceding the width field pads the field with leading zeros (following any indication of sign or base) to the field width, except when applied to an infinity or NaN. This option is only valid for arithmetic types.
other than `charT` and `bool` or when an integer presentation type is specified. If the `0` character and an `align` option both appear, the `0` character is ignored. [Example:

```cpp
char c = 120;
string s1 = format("{:+06d}", c); // value of s1 is "+00120"
string s2 = format("{:06x}", 0xa); // value of s2 is "0x000a"
string s3 = format("{:<06}", -42); // value of s3 is "-42 " (0 is ignored because of < alignment)
```

--- end example]

The `nonnegative-integer` in `precision` is a decimal integer defining the precision or maximum field size. It can only be used with floating-point and string types. For floating-point types this field specifies the formatting precision. For string types, this field provides an upper bound for the estimated width of the prefix of the input string that is copied into the output. For a string in a Unicode encoding, the formatter copies to the output the longest prefix of whole extended grapheme clusters whose estimated width is no greater than the precision.

When the L option is used, the form used for the conversion is called the `locale-specific form`. The L option is only valid for arithmetic types, and its effect depends upon the type.

(15.1) - For integral types, the locale-specific form causes the context’s locale to be used to insert the appropriate digit group separator characters.

(15.2) - For floating-point types, the locale-specific form causes the context’s locale to be used to insert the appropriate digit group and radix separator characters.

(15.3) - For the textual representation of `bool`, the locale-specific form causes the context’s locale to be used to insert the appropriate string as if obtained with `numpunct::truename` or `numpunct::falsename`.

The `type` determines how the data should be presented.

The available string presentation types are specified in Table 61.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none, s</td>
<td>Copies the string to the output.</td>
</tr>
</tbody>
</table>

The meaning of some non-string presentation types is defined in terms of a call to `to_chars`. In such cases, let `{first, last)` be a range large enough to hold the `to_chars` output and `value` be the formatting argument value. Formatting is done as if by calling `to_chars` as specified and copying the output through the output iterator of the format context. [Note: Additional padding and adjustments are performed prior to copying the output through the output iterator as specified by the format specifiers. — end note]

The available integer presentation types for integral types other than `bool` and `charT` are specified in Table 62.

[Example:

```cpp
string s0 = format("{}", 42); // value of s0 is "42"
string s1 = format("{0:b} {0:d} {0:o} {0:x}", 42); // value of s1 is "101010 42 52 2a"
string s2 = format("{0:*} {0:*x}", 42); // value of s2 is "0x2a 0X2A"
string s3 = format("{:L}", 1234); // value of s3 might be "1,234" (depending on the locale)
```

--- end example]

The available `charT` presentation types are specified in Table 63.

The available `bool` presentation types are specified in Table 64.

The available floating-point presentation types and their meanings for values other than infinity and NaN are specified in Table 65. For lower-case presentation types, infinity and NaN are formatted as `inf` and `nan`, respectively. For upper-case presentation types, infinity and NaN are formatted as `INF` and `NAN`, respectively. [Note: In either case, a sign is included if indicated by the `sign` option. — end note]

The available pointer presentation types and their mapping to `to_chars` are specified in Table 66. [Note: Pointer presentation types also apply to `nullptr_t`. — end note]

20.20.3 Error reporting [format.err.report]

Formatting functions throw format_error if an argument fmt is passed that is not a format string for args. They propagate exceptions thrown by operations of formatter specializations and iterators. Failure to allocate storage is reported by throwing an exception as described in 16.5.5.13.

20.20.4 Formatting functions [format.functions]

In the description of the functions, operator + is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of a + n are the same as in 25.2.

```cpp
template<class... Args>
string format(string_view fmt, const Args&... args);
```

Effects: Equivalent to:
```
return vformat(fmt, make_format_args(args...));
```

```cpp
template<class... Args>
wstring format(wstring_view fmt, const Args&... args);
```

Effects: Equivalent to:
```
return vformat(fmt, make_wformat_args(args...));
```

```cpp
template<class... Args>
string format(const locale& loc, string_view fmt, const Args&... args);
```

Effects: Equivalent to:
```
return vformat(loc, fmt, make_format_args(args...));
```

```cpp
template<class... Args>
wstring format(const locale& loc, wstring_view fmt, const Args&... args);
```

Effects: Equivalent to:
```
return vformat(loc, fmt, make_wformat_args(args...));
```

```cpp
string vformat(string_view fmt, format_args args);
```

Returns: A string object holding the character representation of formatting arguments provided by args formatted according to specifications given in fmt. If present, loc is used for locale-specific formatting.

Throws: As specified in 20.20.3.

```cpp
template<class Out, class... Args>
Out format_to(Out out, string_view fmt, const Args&... args);
```

```cpp
template<class Out, class... Args>
Out format_to(Out out, wstring_view fmt, const Args&... args);
```

Effects: Equivalent to:
```
using context = basic_format_context<Out, decltype(fmt)::value_type>;
return vformat_to(out, fmt, make_format_args<context>(args...));
```

```cpp
template<class Out, class... Args>
Out format_to(Out out, const locale& loc, string_view fmt, const Args&... args);
```

```cpp
template<class Out, class... Args>
Out format_to(Out out, const locale& loc, wstring_view fmt, const Args&... args);
```

Effects: Equivalent to:

§ 20.20.4
using context = basic_format_context<Out, decltype(fmt)::value_type>;
return vformat_to(out, loc, fmt, make_format_args<context>(args...));

template<class Out>
Out vformat_to(Out out, string_view fmt,
format_args_t<type_identity_t<Out>, char> args);

template<class Out>
Out vformat_to(Out out, wstring_view fmt,
format_args_t<type_identity_t<Out>, wchar_t> args);

template<class Out>
Out vformat_to(Out out, const locale& loc, string_view fmt,
format_args_t<type_identity_t<Out>, char> args);

template<class Out>
Out vformat_to(Out out, const locale& loc, wstring_view fmt,
format_args_t<type_identity_t<Out>, wchar_t> args);

Let charT be decltype(fmt)::value_type.

Constraints: Out satisfies output_iterator<const charT&>.

Preconditions: Out models output_iterator<const charT&>.

Effects: Places the character representation of formatting the arguments provided by args, formatted according to the specifications given in fmt, into the range [out, out + N), where N is formatted_size(fmt, args...) for the functions without a loc parameter and formatted_size(loc, fmt, args...) for the functions with a loc parameter. If present, loc is used for locale-specific formatting.

Returns: out + N.

Throws: As specified in 20.20.3.

template<class Out, class... Args>
format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
string_view fmt, const Args&... args);

template<class Out, class... Args>
format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
wstring_view fmt, const Args&... args);

template<class Out, class... Args>
format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
const locale& loc, string_view fmt,
const Args&... args);

template<class Out, class... Args>
format_to_n_result<Out> format_to_n(Out out, iter_difference_t<Out> n,
const locale& loc, wstring_view fmt,
const Args&... args);

Let

(16.1) charT be decltype(fmt)::value_type,
(16.2) N be formatted_size(fmt, args...) for the functions without a loc parameter and formatted_size(loc, fmt, args...) for the functions with a loc parameter, and
(16.3) M be clamp(n, 0, N).

Constraints: Out satisfies output_iterator<const charT&>.

Preconditions: Out models output_iterator<const charT&> and formatter<Ti, charT> meets the Formatter requirements (20.20.5.1) for each Ti in Args.

Effects: Places the first M characters of the character representation of formatting the arguments provided by args, formatted according to the specifications given in fmt, into the range [out, out + M). If present, loc is used for locale-specific formatting.

Returns: {out + M, N}.

Throws: As specified in 20.20.3.

template<class... Args>
size_t formatted_size(string_view fmt, const Args&... args);

template<class... Args>
size_t formatted_size(wstring_view fmt, const Args&... args);
template<class... Args>
size_t formatted_size(const locale& loc, string_view fmt, const Args&... args);

Let charT be decltype(fmt)::value_type.

Preconditions: formatter<T_i, charT> meets the Formatter requirements (20.20.5.1) for each T_i in Args.

Returns: The number of characters in the character representation of formatting arguments args formatted according to specifications given in fmt. If present, loc is used for locale-specific formatting.

Throws: As specified in 20.20.3.

20.20.5 Formatter [format.formatter]

20.20.5.1 Formatter requirements [formatter.requirements]

1 A type F meets the Formatter requirements if:

   (1.1) — it meets the

   (1.1.1) — Cpp17DefaultConstructible (Table 27),
   (1.1.2) — Cpp17CopyConstructible (Table 29),
   (1.1.3) — Cpp17CopyAssignable (Table 31), and
   (1.1.4) — Cpp17Destructible (Table 32)

   requirements,

   (1.2) — it is swappable (16.5.3.2) for lvalues, and

   (1.3) — the expressions shown in Table 67 are valid and have the indicated semantics.

2 Given character type charT, output iterator type Out, and formatting argument type T, in Table 67:

   (2.1) — f is a value of type F,
   (2.2) — u is an lvalue of type T,
   (2.3) — t is a value of a type convertible to (possibly const) T,
   (2.4) — PC is basic_format_parse_context<charT>,
   (2.5) — FC is basic_format_context<Out, charT>,
   (2.6) — pc is an lvalue of type PC, and
   (2.7) — fc is an lvalue of type FC.

   pc.begin() points to the beginning of the format-spec (20.20.2) of the replacement field being formatted in the format string. If format-spec is empty then either pc.begin() == pc.end() or *pc.begin() == '}'. [Note: This allows formatters to emit meaningful error messages. — end note] Stores the parsed format specifiers in *this and returns an iterator past the end of the parsed range.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>f.parse(pc)</td>
<td>PC::iterator</td>
<td>Parses format-spec (20.20.2) for type T in the range [pc.begin(), pc.end()) until the first unmatched character. Throws format_error unless the whole range is parsed or the unmatched character is '}.</td>
</tr>
<tr>
<td>f.format(t, fc)</td>
<td>FC::iterator</td>
<td>Formats t according to the specifiers stored in *this, writes the output to fc.out() and returns an iterator past the end of the output range. The output shall only depend on t, fc.locale(), and the range [pc.begin(), pc.end()) from the last call to f.parse(pc).</td>
</tr>
<tr>
<td>f.format(u, fc)</td>
<td>FC::iterator</td>
<td>As above, but does not modify u.</td>
</tr>
</tbody>
</table>
20.20.5.2 Formatter specializations

The functions defined in 20.20.4 use specializations of the class template formatter to format individual arguments.

Let charT be either char or wchar_t. Each specialization of formatter is either enabled or disabled, as described below. [Note: Enabled specializations meet the Formatter requirements, and disabled specializations do not. — end note] Each header that declares the template formatter provides the following enabled specializations:

(2.1) The specializations

```cpp
    template<> struct formatter<char, char>;
    template<> struct formatter<char, wchar_t>;
    template<> struct formatter<wchar_t, wchar_t>;
```

(2.2) For each charT, the string type specializations

```cpp
    template<> struct formatter<charT*, charT>;
    template<> struct formatter<const charT*, charT>;
    template<size_t N> struct formatter<const charT[N], charT>;
    template<class traits, class Allocator>
      struct formatter<basic_string<charT, traits, Allocator>, charT>;
    template<class traits>
      struct formatter<basic_string_view<charT, traits>, charT>;
```

(2.3) For each charT, for each cv-unqualified arithmetic type ArithmeticT other than char, wchar_t, char8_t, char16_t, or char32_t, a specialization

```cpp
    template<> struct(formatter<ArithmeticT, charT>;
```

(2.4) For each charT, the pointer type specializations

```cpp
    template<> struct(formatter<nullptr_t, charT>;
    template<> struct(formatter<void*, charT>;
    template<> struct(formatter<const void*, charT>;
```

The parse member functions of these formatters interpret the format specification as a std-format-spec as described in 20.20.2.2. [Note: Specializations such as formatter<wchar_t, char> and formatter<const char*, wchar_t> that would require implicit multibyte / wide string or character conversion are disabled. — end note] 3 For any types T and charT for which neither the library nor the user provides an explicit or partial specialization of the class template formatter<T, charT> is disabled.

4 If the library provides an explicit or partial specialization of formatter<T, charT>, that specialization is enabled except as noted otherwise.

5 If F is a disabled specialization of formatter, these values are false:

```cpp
    (5.1) - is_default_constructible_v<F>,
    (5.2) - is_copy_constructible_v<F>,
    (5.3) - is_move_constructible_v<F>,
    (5.4) - is_copyAssignable_v<F>, and
    (5.5) - is_moveAssignable_v<F>.
```

6 An enabled specialization formatter<T, charT> meets the Formatter requirements (20.20.5.1). [Example:

```cpp
#include <format>

enum color { red, green, blue };
const char* color_names[] = { "red", "green", "blue" };

    template<> struct std::formatter<color> : std::formatter<const char*> {
        auto format(color c, format_context& ctx) {
            return formatter<const char*>::format(color_names[c], ctx);
        }
    };

    struct err {};

    std::string s0 = std::format("{}", 42); // OK, library-provided formatter
    std::string s1 = std::format("{}", L"foo"); // error: disabled formatter
    std::string s2 = std::format("{}", red); // OK, user-provided formatter
```
std::string s3 = std::format("{}", err{});  // error: disabled formatter

--- end example

### § 20.20.5.3 Class template `basic_format_parse_context`

```cpp
namespace std {
    template<class charT>
    class basic_format_parse_context {
        public:
            using char_type = charT;
            using const_iterator = typename basic_string_view<charT>::const_iterator;
            using iterator = const_iterator;

            private:
                iterator begin_;  // exposition only
                iterator end_;    // exposition only
                enum indexing { unknown, manual, automatic };  // exposition only
                indexing indexing_;  // exposition only
                size_t next_arg_id_;  // exposition only
                size_t num_args_;  // exposition only

            public:
                constexpr explicit basic_format_parse_context(basic_string_view<charT> fmt, 
                    size_t num_args = 0) noexcept;
                basic_format_parse_context(const basic_format_parse_context&) = delete;
                basic_format_parse_context& operator=(const basic_format_parse_context&) = delete;
                constexpr const_iterator begin() const noexcept;
                constexpr const_iterator end() const noexcept;
                constexpr void advance_to(const_iterator it);
                constexpr size_t next_arg_id();
                constexpr void check_arg_id(size_t id);
            }
        }
```
constexpr void check_arg_id(size_t id);

Effects: If indexing_ != automatic, equivalent to:
   if (indexing_ == unknown)
      indexing_ = manual;

Throws: format_error if indexing_ == automatic which indicates mixing of automatic and manual argument indexing.

Remarks: Call expressions where id >= num_args_ are not core constant expressions (7.7).

20.20.5.4 Class template basic_format_context

namespace std {
   template<class Out, class charT>
   class basic_format_context {
      basic_format_args<basic_format_context> args_;  // exposition only
      Out out_;                                        // exposition only

   public:
      using iterator = Out;
      using char_type = charT;
      template<class T> using formatter_type = formatter<T, charT>;

      basic_format_arg<basic_format_context> arg(size_t id) const;
      std::locale locale();
      iterator out();
      void advance_to(iterator it);
   }
}

An instance of basic_format_context holds formatting state consisting of the formatting arguments and the output iterator.

Out shall model output_iterator<const charT&>.

format_context is an alias for a specialization of basic_format_context with an output iterator that appends to string, such as back_insert_iterator<string>. Similarly, wformat_context is an alias for a specialization of basic_format_context with an output iterator that appends to wstring.

[Note: For a given type charT, implementations are encouraged to provide a single instantiation of basic_format_context for appending to basic_string<charT>, vector<charT>, or any other container with contiguous storage by wrapping those in temporary objects with a uniform interface (such as a span<charT>) and polymorphic reallocation. — end note]

basic_format_arg<basic_format_context> arg(size_t id) const;

   Returns: args_.get(id).

std::locale locale();

   Returns: The locale passed to the formatting function if the latter takes one, and std::locale() otherwise.

iterator out();

   Returns: out_.

void advance_to(iterator it);

Effects: Equivalent to: out_ = it;

[Example:
   struct S { int value; }; 

   template<> struct std::formatter<S> {
      size_t width_arg_id = 0; 
}
// Parses a width argument id in the format \{ digit \}.
constexpr auto parse(format_parse_context& ctx) {
  auto iter = ctx.begin();
  auto get_char = [&]() { return iter != ctx.end() ? *iter : 0; };
  if (get_char() != '{')
    return iter;
  ++iter;
  char c = get_char();
  if (!isdigit(c) || (++iter, get_char()) != '}
    throw format_error("invalid format");
  width_arg_id = c - '0';
  ctx.check_arg_id(width_arg_id);
  return ++iter;
}

// Formats an S with width given by the argument width_arg_id.
auto format(S s, format_context& ctx) {
  int width = visit_format_arg(
    [](auto value) -> int {
      if constexpr (!is_integral_v<decltype(value)>)
        throw format_error("width is not integral");
      else if (value < 0 || value > numeric_limits<int>::max())
        throw format_error("invalid width");
      else
        return value;
    },
    ctx.arg(width_arg_id));
  return format_to(ctx.out(), "{0:x<{1}}", s.value, width);
};

std::string s = std::format("{0:{1}}", S{42}, 10); // value of s is "xxxxxxxxx42"
explicit basic_format_arg(nullptr_t) noexcept;  // exposition only

template<class T>
explicit basic_format_arg(const T* p) noexcept;  // exposition only

public:
    basic_format_arg() noexcept;
    explicit operator bool() const noexcept;
};

1 An instance of `basic_format_arg` provides access to a formatting argument for user-defined formatters.

2 The behavior of a program that adds specializations of `basic_format_arg` is undefined.

    basic_format_arg() noexcept;

    Postconditions: !(*this).

    template<class T> explicit basic_format_arg(const T& v) noexcept;

    Constraints: The template specialization

        typename Context::template formatter_type<T>

    meets the `Formatter` requirements (20.20.5.1). The extent to which an implementation determines that the specialization meets the `Formatter` requirements is unspecified, except that as a minimum the expression

        typename Context::template formatter_type<T>()

        .format(declval<const T&>(), declval<Context&>())

    shall be well-formed when treated as an unevaluated operand.

    Effects:

    (5.1) if `T` is `bool` or `char_type`, initializes `value` with `v`;

    (5.2) otherwise, if `T` is `char` and `char_type` is `wchar_t`, initializes `value` with `static_cast<wchar_t>(v)`;

    (5.3) otherwise, if `T` is a signed integer type (6.8.1) and `sizeof(T) <= sizeof(int)`, initializes `value` with `static_cast<int>(v)`;

    (5.4) otherwise, if `T` is an unsigned integer type and `sizeof(T) <= sizeof(unsigned int)`, initializes `value` with `static_cast<unsigned int>(v)`;

    (5.5) otherwise, if `T` is a signed integer type and `sizeof(T) <= sizeof(long long int)`, initializes `value` with `static_cast<long long int>(v)`;

    (5.6) otherwise, if `T` is an unsigned integer type and `sizeof(T) <= sizeof(unsigned long long int)`, initializes `value` with `static_cast<unsigned long long int>(v)`;

    (5.7) otherwise, initializes `value` with `handle(v)`.

    explicit basic_format_arg(float n) noexcept;
    explicit basic_format_arg(double n) noexcept;
    explicit basic_format_arg(long double n) noexcept;

    Effects: Initializes `value` with `n`.

    explicit basic_format_arg(const char_type* s);

    Preconditions: `s` points to a NTCTS (16.3.18).

    Effects: Initializes `value` with `s`.

    template<class traits>
    explicit basic_format_arg(basic_string_view<char_type, traits> s) noexcept;

    Effects: Initializes `value` with `s`.

    template<class traits, class Allocator>
    explicit basic_format_arg(
        const basic_string<char_type, traits, Allocator>& s) noexcept;

    Effects: Initializes `value` with `basic_string_view<char_type>(s.data(), s.size())`. 

§ 20.20.6.1

718
explicit basic_format_arg(nullptr_t) noexcept;

Effects: Initializes value with static_cast<const void*>(nullptr).

template<class T> explicit basic_format_arg(const T* p) noexcept;

Constraints: is_void_v<T> is true.

Effects: Initializes value with p.

[Note: Constructing basic_format_arg from a pointer to a member is ill-formed unless the user provides an enabled specialization of formatter for that pointer to member type. — end note]

explicit operator bool() const noexcept;

Returns: !holds_alternative<monostate>(value).

The class handle allows formatting an object of a user-defined type.

namespace std {
    template<class Context>
    class basic_format_arg<Context>::handle {
    
    public:
        void format(basic_format_parse_context<char_type>&, Context& ctx) const;
    
    template<class T> explicit handle(const T& val) noexcept;
    
    friend class basic_format_arg<Context>;
    
    void format(basic_format_parse_context<char_type>& parse_ctx, Context& format_ctx) const;
    
    template<class Visitor, class Context>
    see below visit_format_arg(Visitor&& vis, basic_format_arg<Context> arg);
    
    Effects: Equivalent to: format_(parse_ctx, format_ctx, ptr_);
    
    template<
class T> explicit handle(const T& val) noexcept;
    
    Effects: Initializes ptr_ with addressof(val) and format_ with

    [](basic_format_parse_context<char_type>& parse_ctx,
            Context& format_ctx, const void* ptr) {
        typename Context::template formatter_type<T> f;
        parse_ctx.advance_to(f.parse(parse_ctx));
        format_ctx.advance_to(f.format(*static_cast<const T*>(ptr), format_ctx));
    }

    void format(basic_format_parse_context<char_type>& parse_ctx, Context& format_ctx) const;
    
    Effects: Equivalent to: format_(parse_ctx, format_ctx, ptr_);
    
    template<class Visitor, class Context>
    see below visit_format_arg(Visitor&& vis, basic_format_arg<Context> arg);
    
    Effects: Equivalent to: return visit(forward<Visitor>(vis), arg.value);

    20.20.6.2 Class template format-arg-store

    namespace std {
        template<class Context = format_context, class... Args>
        struct format-arg-store {
            array<basic_format_arg<Context>, sizeof...(Args)> args;
        };
    }

    An instance of format-arg-store stores formatting arguments.

    template<class Context = format_context, class... Args>
    format-arg-store<Context, Args...> make_format_args(const Args&... args);

    Preconditions: The type typename Context::template formatter_type<T_i> meets the Formatter requirements (20.20.5.1) for each T_i in Args.

    Returns: {basic_format_arg<Context>(args)...}.
template<class... Args>
format-arg-store<wformat_context, Args...> make_wformat_args(const Args&... args);

Effects: Equivalent to: return make_format_args<wformat_context>(args...);

20.20.6.3 Class template basic_format_args

namespace std {

template<class Context>
class basic_format_args {

size_t size_; // exposition only
const basic_format_arg<Context>* data_; // exposition only

public:

basic_format_args() noexcept;

template<class... Args>
basic_format_args(const format-arg-store<Context, Args...>& store) noexcept;

basic_format_arg<Context> get(size_t i) const noexcept;

};

} // namespace std

An instance of basic_format_args provides access to formatting arguments.

basic_format_args() noexcept;

Effects: Initializes size_ with 0.

template<class... Args>
basic_format_args(const format-arg-store<Context, Args...>& store) noexcept;

Effects: Initializes size_ with sizeof...(Args) and data_ with store.args.data().

basic_format_arg<Context> get(size_t i) const noexcept;

Returns: i < size_ ? data_[i] : basic_format_arg<Context>().

[Note: Implementations are encouraged to optimize the representation of basic_format_args for small number of formatting arguments by storing indices of type alternatives separately from values and packing the former. — end note]

20.20.7 Class format_error

namespace std {

class format_error : public runtime_error {

public:

explicit format_error(const string& what_arg);
explicit format_error(const char* what_arg);

};

} // namespace std

The class format_error defines the type of objects thrown as exceptions to report errors from the formatting library.

format_error(const string& what_arg);

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

format_error(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.
21 Strings library

21.1 General

1. This Clause describes components for manipulating sequences of any non-array trivial standard-layout (6.8) type. Such types are called char-like types, and objects of char-like types are called char-like objects or simply characters.

2. The following subclauses describe a character traits class, string classes, and null-terminated sequence utilities, as summarized in Table 68.

<table>
<thead>
<tr>
<th>Subclause Head</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.2 Character traits</td>
<td>&lt;string&gt;</td>
</tr>
<tr>
<td>21.3 String classes</td>
<td>&lt;string_view&gt;</td>
</tr>
<tr>
<td>21.4 String view classes</td>
<td>&lt;ccctype&gt;, &lt;cstring&gt;, &lt;uchar&gt;, &lt;wchar&gt;, &lt;cwctype&gt;</td>
</tr>
<tr>
<td>21.5 Null-terminated sequence utilities</td>
<td>&lt;cstring&gt;</td>
</tr>
</tbody>
</table>

21.2 Character traits

1. This subclause defines requirements on classes representing character traits, and defines a class template `char_traits<charT>`, along with five specializations, `char_traits<char>`, `char_traits<char8_t>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`, that meet those requirements.

2. Most classes specified in 21.3, 21.4, and Clause 29 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by each such template. This subclause defines the semantics of these members.

3. To specialize those templates to generate a string, string view, or iostream class to handle a particular character container type (16.3.3) C, that and its related character traits class X are passed as a pair of parameters to the string, string view, or iostream template as parameters `charT` and `traits`. If `X::char_type` is not the same type as `C`, the program is ill-formed.

21.2.1 Character traits requirements

1. In Table 69, X denotes a traits class defining types and functions for the character container type C; c and d denote values of type C; p and q denote values of type const C*; s denotes a value of type C*; n, i and j denote values of type size_t; e and f denote values of type X::int_type; pos denotes a value of type X::pos_type; and r denotes an lvalue of type C. Operations on X shall not throw exceptions.

<td>constant</td>
</tr>
<tr>
<td><code>X::eof()</code></td>
<td><code>X::int_type</code></td>
<td>Returns: a value ( e ) such that ( X::eq_int_type(e,X::to_int_type(c)) ) is false for all values ( c ).</td>
<td>constant</td>
</tr>
</tbody>
</table>
The class template

```cpp
template<class charT> struct char_traits;
```

is provided in the header `<string>` as a basis for explicit specializations.

### 21.2.2 Traits typedefs

```cpp
using int_type = see below;
```

1. **Preconditions**: `int_type` shall be able to represent all of the valid characters converted from the corresponding `char_type` values, as well as an end-of-file value, `eof()`.

```cpp
using state_type = see below;
```

2. **Preconditions**: `state_type` meets the Cpp17Destructible (Table 32), Cpp17CopyAssignable (Table 31), Cpp17CopyConstructible (Table 29), and Cpp17DefaultConstructible (Table 27) requirements.

### 21.2.3 char_traits specializations

```cpp
namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;
        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}
```

1. The type `mbstate_t` is defined in `<cwchar>` and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

2. The two-argument member `assign` is defined identically to the built-in operator `=`. The two-argument members `eq` and `lt` are defined identically to the built-in operators `==` and `<` for type `unsigned char`.

---

221) If `eof()` can be held in `char_type` then some iostreams operations can give surprising results.
The member `eof()` returns EOF.

21.2.3.2 struct char_traits<char8_t>

```cpp
namespace std {
    template<> struct char_traits<char8_t> {
        using char_type = char8_t;
        using int_type = unsigned int;
        using off_type = streamoff;
        using pos_type = u8streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                               const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}
```

1. The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<` respectively.

2. The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-8 code unit.

21.2.3.3 struct char_traits<char16_t>

```cpp
namespace std {
    template<> struct char_traits<char16_t> {
        using char_type = char16_t;
        using int_type = uint_least16_t;
        using off_type = streamoff;
        using pos_type = u16streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                               const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}
```
The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<`, respectively.

The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

1. The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<`, respectively.

2. The member `eof()` returns an implementation-defined constant that cannot appear as a Unicode code point.

21.2.3.4 `struct char_traits<char32_t>`

```cpp
namespace std {
    template<> struct char_traits<char32_t> {
        using char_type = char32_t;
        using int_type = uint_least32_t;
        using off_type = streamoff;
        using pos_type = u32streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}
```

§ 21.2.3.5 725
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;
}

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and <, respectively.

2 The member eof() returns WEOF.

21.3 String classes

1 The header `<string>` defines the basic_string class template for manipulating varying-length sequences of char-like objects and five typedef-names, string, u8string, u16string, u32string, and wstring, that name the specializations basic_string<char>, basic_string<char8_t>, basic_string<char16_t>, basic_string<char32_t>, and basic_string<wchar_t>, respectively.

21.3.1 Header `<string>` synopsis

```cpp
#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.1
namespace std {

    // 21.2, character traits
    template<class charT> struct char_traits;
    template<> struct char_traits<char>;
    template<> struct char_traits<char8_t>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;

    // 21.3.2, basic_string
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
    class basic_string;

    template<class charT, class traits, class Allocator>
    constexpr basic_string<charT, traits, Allocator>
    operator+(const basic_string<charT, traits, Allocator>& lhs,
               const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
    constexpr basic_string<charT, traits, Allocator>
    operator+(const basic_string<charT, traits, Allocator>&& lhs,
               const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
    constexpr basic_string<charT, traits, Allocator>
    operator+(const charT* lhs,
               const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
    constexpr basic_string<charT, traits, Allocator>
    operator+(const charT* lhs,
               const basic_string<charT, traits, Allocator>&& rhs);
```

§ 21.3.1 726

namespace pmr {
    template<class charT, class traits = char_traits<charT>>
    using basic_string = std::basic_string<charT, traits, polymorphic_allocator<charT>>;
}

§ 21.3.1
The class template `basic_string` describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also called a "string" if the type of the char-like objects that it holds is clear from context. In the rest of this Clause, the type of the char-like objects held in a `basic_string` object is designated by `charT`.

A specialization of `basic_string` is a contiguous container (22.2.1).

In all cases, `data()`, `data() + size()` is a valid range, `data() + size()` points at an object with value `charT()` (a "null terminator"), and `size() <= capacity()` is true.

```c++
namespace std {
  template<class charT, class traits = char_traits<charT>,
           class Allocator = allocator<charT>>
  class basic_string {
    public:
      // types
      using traits_type = traits;
      using value_type = charT;
      using allocator_type = Allocator;
      using size_type = typename allocator_traits<Allocator>::size_type;
      using difference_type = typename allocator_traits<Allocator>::difference_type;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;
      using reference = value_type&;
      using const_reference = const value_type&;

      using iterator = implementation-defined; // see 22.2
      using const_iterator = implementation-defined; // see 22.2
      using reverse_iterator = std::reverse_iterator<iterator>;
      using const_reverse_iterator = std::reverse_iterator<const_iterator>;
      static const size_type npos = -1;
  }

template<class InputIterator,
class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
basic_string(InputIterator, InputIterator, Allocator = Allocator())
-> basic_string<typename iterator_traits<InputIterator>::value_type,
char_traits<typename iterator_traits<InputIterator>::value_type>,
Allocator>;

template<class charT,
class traits,
class Allocator = allocator<charT>>
explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;
template<class charT,
class traits,
class Allocator = allocator<charT>>
basic_string(basic_string_view<charT, traits>,
typename see below::size_type, typename see below::size_type,
const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;
}

A size_type parameter type in a basic_string deduction guide refers to the size_type member type of the type deduced by the deduction guide.

21.3.2.1 General requirements

1 If any operation would cause size() to exceed max_size(), that operation throws an exception object of type length_error.

2 If any member function or operator of basic_string throws an exception, that function or operator has no other effect on the basic_string object.

3 In every specialization basic_string<charT, traits, Allocator>, the type allocator_traits<Allocator>::value_type shall name the same type as charT. Every object of type basic_string<charT, traits, Allocator> uses an object of type Allocator to allocate and free storage for the contained charT objects as needed. The Allocator object used is obtained as described in 22.2.1. In every specialization basic_string<charT, traits, Allocator>, the type traits shall meet the character traits requirements (21.2). [Note: The program is ill-formed if traits::char_type is not the same type as charT. —end note]

4 References, pointers, and iterators referring to the elements of a basic_string sequence may be invalidated by the following uses of that basic_string object:

---

21.3.2.2 Constructors and assignment operators

constexpr explicit basic_string(const Allocator& a) noexcept;

Postconditions: size() is equal to 0.

constexpr basic_string(const basic_string& str);
constexpr basic_string(basic_string&& str) noexcept;

Effects: Constructs an object whose value is that of str prior to this call.

Remarks: In the second form, str is left in a valid but unspecified state.

constexpr basic_string(const basic_string& str, size_type pos,
const Allocator& a = Allocator());
constexpr basic_string(const basic_string& str, size_type pos, size_type n,
const Allocator& a = Allocator());

Effects: Let n be npos for the first overload. Equivalent to:

basic_string(basic_string_view<charT, traits> (str).substr(pos, n), a)

template<class T>
constexpr basic_string(const T& t, size_type pos, size_type n, const Allocator& a = Allocator());

Constraints: is_convertible_v<const T&, basic_string_view<charT, traits>> is true.

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then behaves the same as:

basic_string(sv.substr(pos, n), a);

---

222) For example, as an argument to non-member functions swap() (21.3.3.3), operator>>() (21.3.3.4), and getline() (21.3.3.4), or as an argument to basic_string::swap().

§ 21.3.2.2
template<class T>
    constexpr explicit basic_string(const T& t, const Allocator& a = Allocator());

    Constraints:
    — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
    — is_convertible_v<const T&, const charT*> is false.

    Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then behaves
    the same as basic_string(sv.data(), sv.size(), a).

    constexpr basic_string(const charT* s, size_type n, const Allocator& a = Allocator());

    Preconditions: [s, s + n) is a valid range.

    Effects: Constructs an object whose initial value is the range [s, s + n).

    Postconditions: size() is equal to n, and traits::compare(data(), s, n) is equal to 0.

    constexpr basic_string(const charT* s, const Allocator& a = Allocator());

    Constraints: Allocator is a type that qualifies as an allocator (22.2.1). [Note: This affects class template
    argument deduction. — end note]

    Effects: Equivalent to: basic_string(s, traits::length(s), a).

    constexpr basic_string(size_type n, charT c, const Allocator& a = Allocator());

    Constraints: Allocator is a type that qualifies as an allocator (22.2.1). [Note: This affects class template
    argument deduction. — end note]

    Effects: Constructs an object whose value consists of n copies of c.

    template<class InputIterator>
    constexpr basic_string(InputIterator begin, InputIterator end, const Allocator& a = Allocator());

    Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).

    Effects: Constructs a string from the values in the range [begin, end), as indicated in Table 77.

    constexpr basic_string(initializer_list<charT> il, const Allocator& a = Allocator());

    Effects: Equivalent to basic_string(il.begin(), il.end(), a).

    constexpr basic_string(const basic_string& str, const Allocator& alloc);
    constexpr basic_string(basic_string&& str, const Allocator& alloc);

    Effects: Constructs an object whose value is that of str prior to this call. The stored allocator is constructed
    from alloc. In the second form, str is left in a valid but unspecified state.

    Throws: The second form throws nothing if alloc == str.get_allocator().

    template<class InputIterator, 
    class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
    basic_string(InputIterator, InputIterator, Allocator = Allocator())
    -> basic_string<typename iterator_traits<InputIterator>::value_type, 
    char_traits<typename iterator_traits<InputIterator>::value_type>, 
    Allocator>;

    Constraints: InputIterator is a type that qualifies as an input iterator, and Allocator is a type that qualifies
    as an allocator (22.2.1).

    template<class charT, 
    class traits, 
    class Allocator = allocator<charT>>
    explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())
    -> basic_string<charT, traits, Allocator>;

    template<class charT, 
    class traits, 
    class Allocator = allocator<charT>>
    basic_string(basic_string_view<charT, traits>,
    typename see below::size_type, typename see below::size_type,
const Allocator& = Allocator();
-> basic_string<charT, traits, Allocator>;

Constraints: Allocator is a type that qualifies as an allocator (22.2.1).

constexpr basic_string& operator=(const basic_string& str);

Effects: If *this and str are the same object, has no effect. Otherwise, replaces the value of *this with a copy of str.
Returns: *this.

constexpr basic_string& operator=(basic_string&& str)
noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
allocation_traits<Allocator>::is_always_equal::value);

Effects: Move assigns as a sequence container (22.2), except that iterators, pointers and references may be invalidated.
Returns: *this.

template<class T>
constexpr basic_string& operator=(const T& t);

Constraints:
(27.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(27.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
basic_string_view<charT, traits> sv = t;
return assign(sv);

constexpr basic_string& operator=(const charT* s);

Effects: Equivalent to: return *this = basic_string_view<charT, traits>(s);

constexpr basic_string& operator=(charT c);

Effects: Equivalent to:
return *this = basic_string_view<charT, traits>(addressof(c), 1);

constexpr basic_string& operator=(initializer_list<charT> il);

Effects: Equivalent to:
return *this = basic_string_view<charT, traits>(il.begin(), il.size());

21.3.2.3 Iterator support

constexpr iterator begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;

Returns: An iterator referring to the first character in the string.

constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;

Returns: An iterator which is the past-the-end value.

constexpr reverse_iterator rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(end()).

constexpr reverse_iterator rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(begin()).
21.3.2.4 Capacity

```cpp
constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;
```

1. **Returns:** A count of the number of char-like objects currently in the string.
2. **Complexity:** Constant time.

```cpp
constexpr size_type max_size() const noexcept;
```

3. **Returns:** The largest possible number of char-like objects that can be stored in a basic_string.
4. **Complexity:** Constant time.

```cpp
constexpr void resize(size_type n, charT c);
```

5. **Effects:** Alters the value of *this as follows:
6. 1. If \( n \leq \text{size()} \), erases the last \( \text{size()} - n \) elements.
7. 2. If \( n > \text{size()} \), appends \( n - \text{size()} \) copies of \( c \).

```cpp
constexpr void resize(size_type n);
```

8. **Effects:** Equivalent to `resize(n, charT())`.

```cpp
constexpr size_type capacity() const noexcept;
```

7. **Returns:** The size of the allocated storage in the string.
8. **Complexity:** Constant time.

```cpp
constexpr void reserve(size_type res_arg);
```

9. **Effects:** A directive that informs a basic_string of a planned change in size, so that the storage allocation can be managed accordingly. After reserve(), capacity() is greater or equal to the argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of reserve().
10. **Throws:** length_error if \( \text{res_arg} > \text{max_size()} \) or any exceptions thrown by allocator_traits<Allocator>::allocate.

```cpp
constexpr void shrink_to_fit();
```

11. **Effects:** shrink_to_fit is a non-binding request to reduce capacity() to size(). [Note: The request is non-binding to allow latitude for implementation-specific optimizations. — end note] It does not increase capacity() by causing reallocation.
12. **Complexity:** If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.
13. **Remarks:** Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. [Note: If no reallocation happens, they remain valid. — end note]
14. **Effects:** Equivalent to: `erase(begin(), end());`
15. **Effects:** Equivalent to: `return size() == 0;`

21.3.2.5 Element access

```cpp
constexpr const_reference operator[](size_type pos) const;
constexpr reference operator[](size_type pos);
```

1. **Preconditions:** \( \text{pos} \leq \text{size()} \).
2. **Returns:** *(begin() + pos)* if \( \text{pos} < \text{size()} \). Otherwise, returns a reference to an object of type charT with value charT(), where modifying the object to any value other than charT() leads to undefined behavior.
3. **Throws:** Nothing.
4. **Complexity:** Constant time.
constexpr const_reference at(size_type pos) const;
constexpr reference at(size_type pos);

Returns: operator[](pos).

Throws: out_of_range if pos >= size().

constexpr const charT& front() const;
constexpr charT& front();

Preconditions: !empty().

Effects: Equivalent to: return operator[](0);

constexpr const charT& back() const;
constexpr charT& back();

Preconditions: !empty().

Effects: Equivalent to: return operator[](size() - 1);

21.3.2.6 Modifiers

21.3.2.6.1 basic_string::operator+=

constexpr basic_string& operator+=(const basic_string& str);

Effects: Equivalent to: return append(str);

template<class T>
constexpr basic_string& operator+=(const T& t);

Constraints:
1. is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
2. is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
basic_string_view<charT, traits> sv = t;
return append(sv);

constexpr basic_string& operator+=(const charT* s);

Effects: Equivalent to: return append(s);

constexpr basic_string& operator+=(charT c);

Effects: Equivalent to: return append(size_type{1}, c);

constexpr basic_string& operator+=(initializer_list<charT> il);

Effects: Equivalent to: return append(il);

21.3.2.6.2 basic_string::append

constexpr basic_string& append(const basic_string& str);

Effects: Equivalent to: return append(str.data(), str.size());

constexpr basic_string& append(const basic_string& str, size_type pos, size_type n = npos);

Effects: Equivalent to:
return append(basic_string_view<charT, traits>(str).substr(pos, n));

template<class T>
constexpr basic_string& append(const T& t);

Constraints:
1. is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
2. is_convertible_v<const T&, const charT*> is false.
Effects: Equivalent to:
```cpp
basic_string_view<charT, traits> sv = t;
return append(sv.data(), sv.size());
```

```cpp
template<class T>
constexpr basic_string& append(const T& t, size_type pos, size_type n = npos);
```

Constraints:
- is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
- is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
```cpp
basic_string_view<charT, traits> sv = t;
return append(sv.substr(pos, n));
```

```cpp
constexpr basic_string& append(const charT* s, size_type n);
```

Preconditions: \([s, s + n)\) is a valid range.

Effects: Appends a copy of the range \([s, s + n)\) to the string.

Returns: *this.

```cpp
constexpr basic_string& append(const charT* s);
```

Effects: Equivalent to: return append(s, traits::length(s));

```cpp
constexpr basic_string& append(size_type n, charT c);
```

Effects: Appends n copies of c to the string.

Returns: *this.

```cpp
template<class InputIterator>
constexpr basic_string& append(InputIterator first, InputIterator last);
```

Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).

Effects: Equivalent to: return append(basic_string(first, last, get_allocator()));

```cpp
constexpr basic_string& append(initializer_list<charT> il);
```

Effects: Equivalent to: return append(il.begin(), il.size());

```cpp
constexpr void push_back(charT c);
```

Effects: Equivalent to append(size_type{1}, c).

21.3.2.6.3 basic_string::assign

```cpp
constexpr basic_string& assign(const basic_string& str);
```

Effects: Equivalent to: return *this = str;

```cpp
constexpr basic_string& assign(basic_string&& str)
    noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
              allocator_traits<Allocator>::is_always_equal::value);
```

Effects: Equivalent to: return *this = std::move(str);

```cpp
constexpr basic_string& assign(const basic_string& str, size_type pos, size_type n = npos);
```

Effects: Equivalent to:
```cpp
return assign(basic_string_view<charT, traits>(str).substr(pos, n));
```

```cpp
template<class T>
constexpr basic_string& assign(const T& t);
```

Constraints:
- is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
- is_convertible_v<const T&, const charT*> is false.
Effects: Equivalent to:

```cpp
basic_string_view<charT, traits> sv = t;
return assign(sv.data(), sv.size());
```

template<class T>
constexpr basic_string& assign(const T& t, size_type pos, size_type n = npos);

Constraints:
(6.1)  
— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and

(6.2)  
— is_convertible_v<const T&, const charT*>> is false.

Effects: Equivalent to:

```cpp
basic_string_view<charT, traits> sv = t;
return assign(sv.substr(pos, n));
```

constexpr basic_string& assign(const charT* s, size_type n);

Preconditions: [s, s + n) is a valid range.

Effects: Replaces the string controlled by *this with a copy of the range [s, s + n).

Returns: *this.

constexpr basic_string& assign(const charT* s);

Effects: Equivalent to: return assign(s, traits::length(s));

constexpr basic_string& assign(initializer_list<charT> il);

Effects: Equivalent to: return assign(il.begin(), il.size());

constexpr basic_string& assign(size_type n, charT c);

Effects: Equivalent to:

```cpp
  clear();
  resize(n, c);
```

return *this;

```cpp
constexpr basic_string& assign(InputIterator first, InputIterator last);
```

Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).

Effects: Equivalent to: return assign(basic_string(first, last, get_allocator()));

21.3.2.6.4 basic_string::insert

```cpp
constexpr basic_string& insert(size_type pos, const basic_string& str);
```

Effects: Equivalent to: return insert(pos, str.data(), str.size());

```cpp
constexpr basic_string& insert(size_type pos1, const basic_string& str,
size_type pos2, size_type n = npos);
```

Effects: Equivalent to:

```cpp
  return insert(pos1, basic_string_view<charT, traits>(str), pos2, n);
```

```cpp
template<class T>
constexpr basic_string& insert(size_type pos, const T& t);
```

Constraints:
(3.1)  
— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and

(3.2)  
— is_convertible_v<const T&, const charT*>> is false.

Effects: Equivalent to:

```cpp
basic_string_view<charT, traits> sv = t;
return insert(pos, sv.data(), sv.size());
```
template<class T>
    constexpr basic_string& insert(size_type pos1, const T& t,
        size_type pos2, size_type n = npos);

Constraints:

(5.1)  
    is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(5.2)  
    is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

    basic_string_view<charT, traits> sv = t;
    return insert(pos1, sv.substr(pos2, n));

constexpr basic_string& insert(size_type pos, const charT* s, size_type n);

Preconditions:

[s, s + n) is a valid range.

Effects:

Inserts a copy of the range [s, s + n) immediately before the character at position pos if pos < size(), or otherwise at the end of the string.

Returns: *this.

Throws:

(10.1)  
    out_of_range if pos > size(),
(10.2)  
    length_error if n > max_size() - size(), or
(10.3)  
    any exceptions thrown by allocator_traits<Allocator>::allocate.

constexpr basic_string& insert(size_type pos, const charT* s);

Effects: Equivalent to: return insert(pos, s, traits::length(s));

constexpr basic_string& insert(size_type pos, size_type n, charT c);

Effects: Inserts n copies of c before the character at position pos if pos < size(), or otherwise at the end of the string.

Returns: *this.

Throws:

(14.1)  
    out_of_range if pos > size(),
(14.2)  
    length_error if n > max_size() - size(), or
(14.3)  
    any exceptions thrown by allocator_traits<Allocator>::allocate.

constexpr iterator insert(const_iterator p, charT c);

Preconditions: p is a valid iterator on *this.

Effects: Inserts a copy of c at the position p.

Returns: An iterator which refers to the inserted character.

constexpr iterator insert(const_iterator p, size_type n, charT c);

Preconditions: p is a valid iterator on *this.

Effects: Inserts n copies of c at the position p.

Returns: An iterator which refers to the first inserted character, or p if n == 0.

template<class InputIterator>
    constexpr iterator insert(const_iterator p, InputIterator first, InputIterator last);

Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).

Preconditions: p is a valid iterator on *this.

Effects: Equivalent to insert(p - begin(), basic_string(first, last, get_allocator())).

Returns: An iterator which refers to the first inserted character, or p if first == last.

constexpr iterator insert(const_iterator p, initializer_list<charT> il);

Effects: Equivalent to: return insert(p, il.begin(), il.end());
21.3.2.6.5 basic_string::erase

`constexpr basic_string& erase(size_type pos = 0, size_type n = npos);`

**Effects:** Determines the effective length xlen of the string to be removed as the smaller of n and `size() - pos`. Removes the characters in the range `[begin() + pos, begin() + pos + xlen)`.

**Returns:** `*this`.

**Throws:** `out_of_range` if `pos > size()`.

`constexpr iterator erase(const_iterator p);`

**Preconditions:** p is a valid dereferenceable iterator on `*this`.

**Effects:** Removes the character referred to by `p`.

**Returns:** An iterator which points to the element immediately following `p` prior to the element being erased. If no such element exists, `end()` is returned.

**Throws:** Nothing.

`constexpr iterator erase(const_iterator first, const_iterator last);`

**Preconditions:** `first` and `last` are valid iterators on `*this`. `[first, last)` is a valid range.

**Effects:** Removes the characters in the range `[first, last)`.

**Returns:** An iterator which points to the element pointed to by `last` prior to the other elements being erased. If no such element exists, `end()` is returned.

**Throws:** Nothing.

`constexpr void pop_back();`

**Preconditions:** `!empty()`.

**Effects:** Equivalent to `erase(end() - 1)`.

**Throws:** Nothing.

21.3.2.6.6 basic_string::replace

`constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str);`

**Effects:** Equivalent to: return `replace(pos1, n1, str.data(), str.size());`

`constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str, size_type pos2, size_type n2 = npos);`

**Effects:** Equivalent to:

```
return replace(pos1, n1, basic_string_view<charT, traits>((str).substr(pos2, n2));
```

**Constraints:**

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.

**Effects:** Equivalent to:

```
basic_string_view<charT, traits> sv = t;
return replace(pos1, n1, sv.data(), sv.size());
```

**Constraints:**

- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- `is_convertible_v<const T&, const charT*>` is false.
Effects: Equivalent to:
    basic_string_view<charT, traits> sv = t;
    return replace(pos1, n1, sv.substr(pos2, n2));

constexpr basic_string& replace(size_type pos1, size_type n1, const charT* s, size_type n2);

Preconditions: [s, s + n2) is a valid range.

Effects: Determines the effective length xlen of the string to be removed as the smaller of n1 and size() - pos1. If size() - xlen >= max_size() - n2 throws length_error. Otherwise, the function replaces the characters in the range [begin() + pos1, begin() + pos1 + xlen) with a copy of the range [s, s + n2).

Returns: *this.

Throws:

  - out_of_range if pos1 > size(),
  - length_error if the length of the resulting string would exceed max_size(), or
  - any exceptions thrown by allocator_traits<Allocator>::allocate.

constexpr basic_string& replace(size_type pos, size_type n, const charT* s);

Effects: Equivalent to: return replace(pos, n, s, traits::length(s));

constexpr basic_string& replace(size_type pos1, size_type n1, size_type n2, charT c);

Effects: Determines the effective length xlen of the string to be removed as the smaller of n1 and size() - pos1. If size() - xlen >= max_size() - n2 throws length_error. Otherwise, the function replaces the characters in the range [begin() + pos1, begin() + pos1 + xlen) with n2 copies of c.

Returns: *this.

Throws:

  - out_of_range if pos1 > size(),
  - length_error if the length of the resulting string would exceed max_size(), or
  - any exceptions thrown by allocator_traits<Allocator>::allocate.

constexpr basic_string& replace(const_iterator i1, const_iterator i2, const basic_string& str);

Effects: Equivalent to: return replace(i1, i2, basic_string_view<charT, traits>(str));

template<class T>
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const T& t);

Constraints:

  - is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
  - is_convertible_v<const T&, const charT*> is false.

Preconditions: [begin(), i1) and [i1, i2) are valid ranges.

Effects: Equivalent to:
    basic_string_view<charT, traits> sv = t;
    return replace(i1 - begin(), i2 - i1, sv.data(), sv.size());

constexpr basic_string& replace(const_iterator i1, const_iterator i2, const charT* s, size_type n);

Effects: Equivalent to: return replace(i1, i2, basic_string_view<charT, traits>(s, n));

constexpr basic_string& replace(const_iterator i1, const_iterator i2, const charT* s);

Effects: Equivalent to: return replace(i1, i2, basic_string_view<charT, traits>(s));

constexpr basic_string& replace(const_iterator i1, const_iterator i2, size_type n, charT c);

Preconditions: [begin(), i1) and [i1, i2) are valid ranges.

Effects: Equivalent to: return replace(i1 - begin(), i2 - i1, n, c);
template<class InputIterator>
constexpr basic_string& replace(const_iterator i1, const_iterator i2, InputIterator j1, InputIterator j2);

Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).

Effects: Equivalent to: return replace(i1, i2, basic_string(j1, j2, get_allocator()));

constexpr basic_string& replace(const_iterator i1, const_iterator i2, initializer_list<charT> il);

Effects: Equivalent to: return replace(i1, i2, il.begin(), il.size());

21.3.2.6.7 basic_string::copy
constexpr size_type copy(charT* s, size_type n, size_type pos = 0) const;

Effects: Equivalent to: return basic_string_view<charT, traits>(*this).copy(s, n, pos); [Note: This does not terminate s with a null object. — end note]

21.3.2.6.8 basic_string::swap
constexpr void swap(basic_string& s) noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
allocator_traits<Allocator>::is_always_equal::value);

Preconditions: allocator_traits<Allocator>::propagate_on_container_swap::value is true or get_allocator() == s.get_allocator().

Postconditions: *this contains the same sequence of characters that was in s, s contains the same sequence of characters that was in *this.

Throws: Nothing.

Complexity: Constant time.

21.3.2.7 String operations

21.3.2.7.1 Accessors
constexpr const charT* c_str() const noexcept;
constexpr const charT* data() const noexcept;

Returns: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()].

Complexity: Constant time.

Remarks: The program shall not modify any of the values stored in the character array; otherwise, the behavior is undefined.

constexpr charT* data() noexcept;

Returns: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()].

Complexity: Constant time.

Remarks: The program shall not modify the value stored at p + size() to any value other than charT(); otherwise, the behavior is undefined.

constexpr operator basic_string_view<charT, traits>() const noexcept;

Effects: Equivalent to: return basic_string_view<charT, traits>(data(), size());

constexpr allocator_type get_allocator() const noexcept;

Returns: A copy of the Allocator object used to construct the string or, if that allocator has been replaced, a copy of the most recent replacement.

21.3.2.7.2 Searching
Let $F$ be one of find, rfind, find_first_of, find_last_of, find_first_not_of, and find_last_not_of.

Each member function of the form

```cpp
constexpr size_type F(const basic_string& str, size_type pos) const noexcept;
```

has effects equivalent to: return $F$($this$.view<charT, traits>(), pos);
— Each member function of the form
  constexpr size_type F(const charT* s, size_type pos) const;
has effects equivalent to:
  return F(basic_string_view<charT, traits>(s), pos);

— Each member function of the form
  constexpr size_type F(const charT* s, size_type pos, size_type n) const;
has effects equivalent to:
  return F(basic_string_view<charT, traits>(s, n), pos);

— Each member function of the form
  constexpr size_type F(charT c, size_type pos) const noexcept;
has effects equivalent to:
  return F(basic_string_view<charT, traits>(addressof(c), 1), pos);

template<class T>
  constexpr size_type find(const T& t, size_type pos = 0) const noexcept;
template<class T>
  constexpr size_type rfind(const T& t, size_type pos = npos) const noexcept;
template<class T>
  constexpr size_type find_first_of(const T& t, size_type pos = 0) const noexcept;
template<class T>
  constexpr size_type find_last_of(const T& t, size_type pos = npos) const noexcept;
template<class T>
  constexpr size_type find_first_not_of(const T& t, size_type pos = 0) const noexcept;
template<class T>
  constexpr size_type find_last_not_of(const T& t, size_type pos = npos) const noexcept;

2 Constraints:
— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*> is false.

3 Effects: Let G be the name of the function. Equivalent to:
  basic_string_view<charT, traits> s = *this, sv = t;
  return s.G(sv, pos);

4 Remarks: The expression inside noexcept is equivalent to is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>.

21.3.2.7.3 basic_string::substr

constexpr basic_string substr(size_type pos = 0, size_type n = npos) const;

1 Effects: Determines the effective length rlen of the string to copy as the smaller of n and size() - pos.
2 Returns: basic_string(data()+pos, rlen).
3 Throws: out_of_range if pos > size().

21.3.2.7.4 basic_string::compare

template<class T>
  constexpr int compare(const T& t) const noexcept;
template<class T>
  constexpr int compare(size_type pos1, size_type n1, const T& t) const;

1 Constraints:
— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*> is false.

2 Effects: Equivalent to: return basic_string_view<charT, traits>(*this).compare(t);
3 Remarks: The expression inside noexcept is equivalent to is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>.

§ 21.3.2.7.4 745
— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

```cpp
return basic_string_view<charT, traits>(*this).substr(pos1, n1).compare(t);
```

template<class T>
constexpr int compare(size_type pos1, size_type n1, const T& t,
  size_type pos2, size_type n2 = npos) const;

Constraints:
— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

```cpp
basic_string_view<charT, traits> s = *this, sv = t;
return s.substr(pos1, n1).compare(sv.substr(pos2, n2));
```

constexpr int compare(const basic_string& str) const noexcept;

Effects: Equivalent to:

```cpp
return compare(basic_string_view<charT, traits>(str));
```

custom int compare(size_type pos1, size_type n1, const basic_string& str) const;

Effects: Equivalent to:

```cpp
return compare(pos1, n1, basic_string_view<charT, traits>(str));
```

custom int compare(size_type pos1, size_type n1, const basic_string& str,
  size_type pos2, size_type n2 = npos) const;

Effects: Equivalent to:

```cpp
return compare(pos1, n1, basic_string_view<charT, traits>(str), pos2, n2);
```

custom int compare(const charT* s) const;

Effects: Equivalent to:

```cpp
return compare(basic_string_view<charT, traits>(s));
```

custom int compare(size_type pos, size_type n1, const charT* s) const;

Effects: Equivalent to:

```cpp
return compare(pos, n1, basic_string_view<charT, traits>(s));
```

custom int compare(size_type pos, size_type n1, const charT* s, size_type n2) const;

Effects: Equivalent to:

```cpp
return compare(pos, n1, basic_string_view<charT, traits>(s, n2));
```

### 21.3.2.7.5 basic_string::starts_with

```cpp
constexpr bool starts_with(basic_string_view<charT, traits> x) const noexcept;
custom bool starts_with(charT x) const noexcept;
custom bool starts_with(const charT* x) const;
```

Effects: Equivalent to:

```cpp
return basic_string_view<charT, traits>(data(), size()).starts_with(x);
```

### 21.3.2.7.6 basic_string::ends_with

```cpp
constexpr bool ends_with(basic_string_view<charT, traits> x) const noexcept;
custom bool ends_with(charT x) const noexcept;
custom bool ends_with(const charT* x) const;
```

Effects: Equivalent to:

```cpp
return basic_string_view<charT, traits>(data(), size()).ends_with(x);
```

### 21.3.3 Non-member functions

#### 21.3.3.1 operator+

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
  operator+(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs);
```

§ 21.3.3.1
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

1  Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = lhs;
   r.append(rhs);
   return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, const charT* rhs);

2  Effects: Equivalent to:
   lhs.append(rhs);
   return std::move(lhs);

   except that both lhs and rhs are left in valid but unspecified states. [Note: If lhs and rhs have equal allocators,
the implementation may move from either.  — end note]

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, basic_string<charT, traits, Allocator>&& rhs);

3  Effects: Equivalent to:
   lhs.append(rhs);
   return std::move(lhs);

   template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, basic_string<charT, traits, Allocator>&& rhs);

4  Effects: Equivalent to:
   rhs.insert(0, lhs);
   return std::move(rhs);

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, basic_string<charT, traits, Allocator>&& rhs);

5  Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = rhs;
   r.insert(0, lhs);
   return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, const basic_string<charT, traits, Allocator>& rhs);

6  Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = rhs;
   r.insert(r.begin(), lhs);
   return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, basic_string<charT, traits, Allocator>&& rhs);

**Effects:** Equivalent to:
```cpp
rhs.insert(rhs.begin(), lhs);
return std::move(rhs);
```

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, charT rhs);
```

**Effects:** Equivalent to:
```cpp
basic_string<charT, traits, Allocator> r = lhs;
r.push_back(rhs);
return r;
```

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, charT rhs);
```

**Effects:** Equivalent to:
```cpp
lhs.push_back(rhs);
return std::move(lhs);
```

### 21.3.3.2 Non-member comparison functions

```cpp
template<class charT, class traits, class Allocator>
constexpr bool
operator==(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

```cpp
template<class charT, class traits, class Allocator>
constexpr bool operator==(const basic_string<charT, traits, Allocator>& lhs,
            const charT* rhs);
```

```cpp
template<class charT, class traits, class Allocator>
constexpr
 operator<=>(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

```cpp
template<class charT, class traits, class Allocator>
constexpr
 operator<=>(const basic_string<charT, traits, Allocator>& lhs,
            const charT* rhs);
```

**Effects:** Let `op` be the operator. Equivalent to:
```cpp
return basic_string_view<charT, traits>(lhs) op basic_string_view<charT, traits>(rhs);
```

### 21.3.3.3 swap

```cpp
template<class charT, class traits, class Allocator>
constexpr void
swap(basic_string<charT, traits, Allocator>& lhs,
     basic_string<charT, traits, Allocator>& rhs) noexcept(noexcept(lhs.swap(rhs)));
```

**Effects:** Equivalent to `lhs.swap(rhs)`.

### 21.3.3.4 Inserters and extractors

```cpp
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>&& is, basic_string<charT, traits, Allocator>& str);
```

**Effects:** Behaves as a formatted input function (29.7.4.2.1). After constructing a sentry object, if the sentry converts to true, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)`. If `is.width()` is greater than zero, the maximum number `n` of characters appended is `is.width()`; otherwise `n` is `str.max_size()`. Characters are extracted and appended until any of the following occurs:

1. `n` characters are stored;
2. end-of-file occurs on the input sequence;
— isspace(c, is.getloc()) is true for the next available input character c.

After the last character (if any) is extracted, is.width(0) is called and the sentry object is destroyed.

If the function extracts no characters, it calls is.setstate(ios_base::failbit), which may throw ios_base::failure (29.5.5.4).

Returns: is.

template<class charT, class traits, class Allocator>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const basic_string<charT, traits, Allocator>& str);

Effects: Equivalent to: return os << basic_string_view<charT, traits>(str);

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
gline(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str, charT delim);
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
gline(basic_istream<charT, traits>&& is, basic_string<charT, traits, Allocator>& str, charT delim);

Effects: Behaves as an unformatted input function (29.7.4.3), except that it does not affect the value returned by subsequent calls to basic_istream::gcount(). After constructing a sentry object, if the sentry converts to true, calls str.erase() and then extracts characters from is and appends them to str as if by calling str.append(1, c) until any of the following occurs:

— end-of-file occurs on the input sequence (in which case, the getline function calls is.setstate(ios_base::eofbit)).

— traits::eq(c, delim) for the next available input character c (in which case, c is extracted but not appended) (29.5.5.4)

— str.max_size() characters are stored (in which case, the function calls is.setstate(ios_base::failbit)) (29.5.5.4)

The conditions are tested in the order shown. In any case, after the last character is extracted, the sentry object is destroyed.

Returns: is.

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
gline(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str);

Returns: getline(is, str, is.widen(’\n’)).
template<class charT, class traits, class Allocator, class Predicate>
constexpr typename basic_string<charT, traits, Allocator>::size_type
erase_if(basic_string<charT, traits, Allocator>& c, Predicate pred);

Effects: Equivalent to:
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

21.3.4 Numeric conversions

int stoi(const string& str, size_t* idx = nullptr, int base = 10);
long stol(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const string& str, size_t* idx = nullptr, int base = 10);
long long stoll(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const string& str, size_t* idx = nullptr, int base = 10);

Effects: The first two functions call strtol(str.c_str(), ptr, base), and the last three functions call
stoul(str.c_str(), ptr, base), stoll(str.c_str(), ptr, base), and stoull(str.c_str(),
ptr, base), respectively. Each function returns the converted result, if any. The argument ptr designates a
pointer to an object internal to the function that is used to determine what to store at *idx. If the function does
not throw an exception and idx != nullptr, the function stores in *idx the index of the first unconverted
element of str.

Returns: The converted result.

float stof(const string& str, size_t* idx = nullptr);
double stod(const string& str, size_t* idx = nullptr);
long double stold(const string& str, size_t* idx = nullptr);

Effects: These functions call strtof(str.c_str(), ptr), strtod(str.c_str(), ptr), and strtold(
str.c_str(), ptr), respectively. Each function returns the converted result, if any. The argument ptr
designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the
function does not throw an exception and idx != nullptr, the function stores in *idx the index of the first
unconverted element of str.

Returns: The converted result.

float stof(const wstring& str, size_t* idx = nullptr);
double stod(const wstring& str, size_t* idx = nullptr);
long double stold(const wstring& str, size_t* idx = nullptr);

21.3.4 Numeric conversions

§ 21.3.4 750

string to_string(int val);
string to_string(unsigned val);
string to_string(long val);
string to_string(unsigned long val);
string to_string(long long val);
string to_string(float val);
string to_string(double val);

Returns: Each function returns a string object holding the character representation of the value of its argument
that would be generated by calling sprintf(buf, fmt, val) with a format specifier of "%d", "%u", "%ld",
"%lu", "%lld", "%llu", "%f", "%e", or "%f", respectively, where buf designates an internal character buffer of
sufficient size.

int stoi(const wstring& str, size_t* idx = nullptr, int base = 10);
long stol(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const wstring& str, size_t* idx = nullptr, int base = 10);
long long stoll(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const wstring& str, size_t* idx = nullptr, int base = 10);

Effects: The first two functions call wcstol(str.c_str(), ptr, base), and the last three functions call wcstoul(str.c_str(), ptr, base), wcstoll(str.c_str(), ptr, base), and wcstoull(str.c_str(), ptr, base), respectively. Each function returns the converted result, if any. The argument ptr designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != nullptr, the function stores in *idx the index of the first unconverted element of str.

Returns: The converted result.

Throws: invalid_argument if wcstol, wcstoul, wcstoll, or wcstoull reports that no conversion could be performed. Throws out_of_range if the converted value is outside the range of representable values for the return type.

float stof(const wstring& str, size_t* idx = nullptr);
double stod(const wstring& str, size_t* idx = nullptr);
long double stold(const wstring& str, size_t* idx = nullptr);

Effects: These functions call wcstof(str.c_str(), ptr), wcstod(str.c_str(), ptr), and wcstold(str.c_str(), ptr), respectively. Each function returns the converted result, if any. The argument ptr designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != nullptr, the function stores in *idx the index of the first unconverted element of str.

Returns: The converted result.

Throws: invalid_argument if wcstof, wcstod, or wcstold reports that no conversion could be performed. Throws out_of_range if wcstof, wcstod, or wcstold sets errno to ERANGE.

wstring to_wstring(int val);
wstring to_wstring(unsigned val);
wstring to_wstring(long val);
wstring to_wstring(unsigned long val);
wstring to_wstring(long long val);
wstring to_wstring(float val);
wstring to_wstring(double val);
wstring to_wstring(long double val);

Returns: Each function returns a wstring object holding the character representation of the value of its argument that would be generated by calling swprintf(buf, buffsz, fmt, val) with a format specifier of L"%d", L"%u", L"%ld", L"%lu", L"%lld", L"%llu", L"%f", L"%e", or L"%Lf", respectively, where buf designates an internal character buffer of sufficient size buffsz.

21.3.5 Hash support

template<> struct hash<string>;
template<> struct hash<u8string>;
template<> struct hash<u16string>;
template<> struct hash<u32string>;
template<> struct hash<wstring>;
template<> struct hash<pmr::string>;
template<> struct hash<pmr::u8string>;
template<> struct hash<pmr::u16string>;
template<> struct hash<pmr::u32string>;
template<> struct hash<pmr::wstring>;

If S is one of these string types, SV is the corresponding string view type, and s is an object of type S, then hash<S>()(s) == hash<SV>()(SV(s)).

21.3.6 Suffix for basic_string literals

constexpr string operator"s(const char* str, size_t len);

Returns: string(str, len).
constexpr u8string operator""s(const char8_t* str, size_t len);

2 Returns: u8string{str, len}.

constexpr u16string operator""s(const char16_t* str, size_t len);

Returns: u16string{str, len}.

constexpr u32string operator""s(const char32_t* str, size_t len);

Returns: u32string{str, len}.

constexpr wstring operator""s(const wchar_t* str, size_t len);

Returns: wstring{str, len}.

[Note: The same suffix s is used for chrono::duration literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note]

21.4 String view classes

1 The class template basic_string_view describes an object that can refer to a constant contiguous sequence of char-like (21.1) objects with the first element of the sequence at position zero. In the rest of this subclause, the type of the char-like objects held in a basic_string_view object is designated by charT.

2 [Note: The library provides implicit conversions from const charT* and std::basic_string<charT, ...> to std::basic_string_view<charT, ...> so that user code can accept just std::basic_string_view<charT> as a non-templated parameter wherever a sequence of characters is expected. User-defined types should define their own implicit conversions to std::basic_string_view in order to interoperate with these functions. — end note]

21.4.1 Header <string_view> synopsis

#include <compare> // see 17.11.1

namespace std {
    // 21.4.2, class template basic_string_view
    template<class charT, class traits = char_traits<charT>>
    class basic_string_view;

    template<class charT, class traits>
    inline constexpr bool ranges::enable_view<basic_string_view<charT, traits>> = true;

    template<class charT, class traits>
    inline constexpr bool ranges::enable_borrowed_range<basic_string_view<charT, traits>> = true;

    // 21.4.4, non-member comparison functions
    template<class charT, class traits>
    constexpr bool operator==(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;

    template<class charT, class traits>
    constexpr see below operator<=>(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;

    // see 21.4.4, sufficient additional overloads of comparison functions

    // 21.4.5, inserters and extractors
    template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<=(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);

    // basic_string_view typedef names
    using string_view = basic_string_view<char>;
    using u8string_view = basic_string_view<char8_t>;
    using u16string_view = basic_string_view<char16_t>;
    using u32string_view = basic_string_view<char32_t>;
    using wstring_view = basic_string_view<wchar_t>;

§ 21.4.1
The function templates defined in 20.2.2 and 23.7 are available when `<string_view>` is included.

21.4.2 Class template `basic_string_view`  

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_string_view {
public:
    // types
    using traits_type = traits;
    using value_type = charT;
    using pointer = value_type*;
    using const_pointer = const value_type*;
    using reference = value_type&;
    using const_reference = const value_type&;
    using const_iterator = implementation-defined; // see 21.4.2.2
    using iterator = const_iterator;
    using const_reverse_iterator = reverse_iterator<const_iterator>
    using reverse_iterator = const_reverse_iterator;
    using size_type = size_t;
    using difference_type = ptrdiff_t;
    static constexpr size_type npos = size_type(-1);

    // 21.4.2.1, construction and assignment
    constexpr basic_string_view() noexcept;
    constexpr basic_string_view(const basic_string_view&) noexcept = default;
    constexpr basic_string_view& operator=(const basic_string_view&) noexcept = default;
    constexpr basic_string_view(const charT* str);
    constexpr basic_string_view(const charT* str, size_type len);
    template<class It, class End>
    constexpr basic_string_view(It begin, End end);

    // 21.4.2.2, iterator support
    constexpr const_iterator begin() const noexcept;
    constexpr const_iterator end() const noexcept;
    constexpr const_iterator cbegin() const noexcept;
    constexpr const_iterator cend() const noexcept;
    constexpr const_reverse_iterator rbegin() const noexcept;
    constexpr const_reverse_iterator rend() const noexcept;
    constexpr const_reverse_iterator crbegin() const noexcept;
    constexpr const_reverse_iterator crend() const noexcept;

```

223) Because `basic_string_view` refers to a constant sequence, `iterator` and `const_iterator` are the same type.
// 21.4.2.3, capacity
constexpr size_type() const noexcept;
constexpr size_type length() const noexcept;
constexpr size_type max_size() const noexcept;
[[nodiscard]] constexpr bool empty() const noexcept;

// 21.4.2.4, element access
constexpr const_reference operator[](size_type pos) const;
constexpr const_reference at(size_type pos) const;

constexpr size_type find_first_of(charT c, size_type pos = 0) const noexcept;
constexpr size_type find_first_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_first_of(const charT* s, size_type pos = 0) const;
constexpr size_type find_last_of(basic_string_view s, size_type pos = npos) const noexcept;
constexpr size_type find_last_of(charT c, size_type pos = npos) const noexcept;
constexpr size_type find_last_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_last_of(const charT* s, size_type pos = npos) const;
constexpr size_type find_first_not_of(basic_string_view s, size_type pos = 0) const noexcept;
constexpr size_type find_first_not_of(charT c, size_type pos = 0) const noexcept;
constexpr size_type find_first_not_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_first_not_of(const charT* s, size_type pos = 0) const;
constexpr size_type find_last_not_of(basic_string_view s, size_type pos = npos) const noexcept;
constexpr size_type find_last_not_of(charT c, size_type pos = npos) const noexcept;
constexpr size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_last_not_of(const charT* s, size_type pos = npos) const;

private:
    const_pointer data_;  // exposition only
    size_type size_;       // exposition only
};

// 21.4.3, deduction guide
template<class It, class End>
    basic_string_view(It, End) -> basic_string_view<iter_value_t<It>>;

1 In every specialization basic_string_view<charT, traits>, the type traits shall meet the character traits requirements (21.2). [Note: The program is ill-formed if traits::char_type is not the same type as charT. — end note]

2 For a basic_string_view str, any operation that invalidates a pointer in the range [str.data(), str.data() + str.size()) invalidates pointers, iterators, and references returned from str’s member functions.

3 The complexity of basic_string_view member functions is Θ(1) unless otherwise specified.

21.4.2.1 Construction and assignment [string.view.cons]

constexpr basic_string_view() noexcept;
1 Postconditions: size_ == 0 and data_ == nullptr.

constexpr basic_string_view(const charT* str);
2 Preconditions: [str, str + traits::length(str)) is a valid range.
3 Effects: Constructs a basic_string_view, initializing data_ with str and initializing size_ with traits::length(str).
4 Complexity: Θ(traits::length(str)).

constexpr basic_string_view(const charT* str, size_type len);
5 Preconditions: [str, str + len) is a valid range.
6 Effects: Constructs a basic_string_view, initializing data_ with str and initializing size_ with len.

template<class It, class End>
    constexpr basic_string_view(It begin, End end);
7 Constraints:
(7.1) — It satisfies contiguous_iterator.
(7.2) — End satisfies sized_sentinel_for<It>.
(7.3) — is_same_v<iter_value_t<It>, charT> is true.
(7.4) — is_convertible_v<End, size_type> is false.
8 Preconditions:
(8.1) — [begin, end) is a valid range.
(8.2) — It models contiguous_iterator.
(8.3) — End models sized_sentinel_for<It>.
9 Effects: Initializes data_ with to_address(begin) and initializes size_ with end - begin.

21.4.2.2 Iterator support [string.view.iterators]

using const_iterator = implementation-defined;
1 A type that meets the requirements of a constant Cpp17RandomAccessIterator (23.3.5.6), models contiguous_iterator (23.3.4.14), and meets the constexpr iterator requirements (23.3.1), whose value_type is the template parameter charT.
2 All requirements on container iterators (22.2) apply to basic_string_view::const_iterator as well.

§ 21.4.2.2 755
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;

Returns: An iterator such that
- if !empty(), 
  addressof(*begin()) == data_,
- otherwise, an unspecified value such that [begin(), end()) is a valid range.

constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;

Returns: begin() + size().

constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;

Returns: const_reverse_iterator(end()).

constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

Returns: const_reverse_iterator(begin()).

21.4.2.3 Capacity

constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;

Returns: size_.

constexpr size_type max_size() const noexcept;

Returns: The largest possible number of char-like objects that can be referred to by a basic_string_view.
[[nodiscard]] constexpr bool empty() const noexcept;

Returns: size_ == 0.

21.4.2.4 Element access

constexpr const_reference operator[](size_type pos) const;

Preconditions: pos < size().
Returns: data_[pos].
Throws: Nothing.

[Note: Unlike basic_string::operator[], basic_string_view::operator[](size()) has undefined behavior instead of returning charT(). — end note]

constexpr const_reference at(size_type pos) const;

Returns: data_[pos].
Throws: out_of_range if pos >= size().

constexpr const_reference front() const;
Preconditions: !empty().
Returns: data_[0].
Throws: Nothing.

constexpr const_reference back() const;
Preconditions: !empty().
Returns: data_[size() - 1].
Throws: Nothing.

constexpr const_pointer data() const noexcept;

Returns: data_.
[Note: Unlike basic_string::data() and string-literals, data() may return a pointer to a buffer that is not null-terminated. Therefore it is typically a mistake to pass data() to a function that takes just a const charT* and expects a null-terminated string. — end note]

21.4.2.5 Modifiers

```cpp
constexpr void remove_prefix(size_type n);
```

1
Preconditions: n <= size().

2
Effects: Equivalent to: data_ += n; size_ -= n;

```cpp
constexpr void remove_suffix(size_type n);
```

3
Preconditions: n <= size().

4
Effects: Equivalent to: size_ -= n;

```cpp
constexpr void swap(basic_string_view& s) noexcept;
```

5
Effects: Exchanges the values of *this and s.

21.4.2.6 String operations

```cpp
constexpr size_type copy(charT* s, size_type n, size_type pos = 0) const;
```

1
Let rlen be the smaller of n and size() - pos.

2
Preconditions: [s, s + rlen) is a valid range.

3
Effects: Equivalent to traits::copy(s, data() + pos, rlen).

4
Returns: rlen.

5
Throws: out_of_range if pos > size().

6
Complexity: $O(rlen)$.

```cpp
constexpr basic_string_view substr(size_type pos = 0, size_type n = npos) const;
```

7
Let rlen be the smaller of n and size() - pos.

8
Effects: Determines rlen, the effective length of the string to reference.

9
Returns: basic_string_view(data() + pos, rlen).

10
 Throws: out_of_range if pos > size().

11
Complexity: $\Theta(rlen)$.

```cpp
constexpr int compare(basic_string_view str) const noexcept;
```

12
Let rlen be the smaller of size() and str.size().

13
Effects: Determines rlen, the effective length of the strings to compare. The function then compares the two strings by calling traits::compare(data(), str.data(), rlen).

14
Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 70.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; str.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == str.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; str.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

15
Complexity: $O(rlen)$.

```cpp
constexpr int compare(size_type pos1, size_type n1, basic_string_view str) const;
```

16
Effects: Equivalent to: return substr(pos1, n1).compare(str);

```cpp
constexpr int compare(size_type pos1, size_type n1, basic_string_view str, size_type pos2, size_type n2) const;
```

17
Effects: Equivalent to: return substr(pos1, n1).compare(str.substr(pos2, n2));
constexpr int compare(const charT* s) const;

Effects: Equivalent to: return compare(basic_string_view(s));

constexpr int compare(size_type pos1, size_type n1, const charT* s) const;

Effects: Equivalent to: return substr(pos1, n1).compare(basic_string_view(s));

constexpr int compare(size_type pos1, size_type n1, const charT* s, size_type n2) const;

Effects: Equivalent to: return substr(pos1, n1).compare(basic_string_view(s, n2));

constexpr bool starts_with(basic_string_view x) const noexcept;

Effects: Equivalent to: return substr(0, x.size()) == x;

constexpr bool starts_with(charT x) const noexcept;

Effects: Equivalent to: return !empty() && traits::eq(front(), x);

constexpr bool starts_with(const charT* x) const;

Effects: Equivalent to: return starts_with(basic_string_view(x));

constexpr bool ends_with(basic_string_view x) const noexcept;

Effects: Equivalent to:
return size() >= x.size() && compare(size() - x.size(), npos, x) == 0;

constexpr bool ends_with(charT x) const noexcept;

Effects: Equivalent to: return !empty() && traits::eq(back(), x);

constexpr bool ends_with(const charT* x) const;

Effects: Equivalent to: return ends_with(basic_string_view(x));

21.4.2.7 Searching [string.view.find]

Member functions in this subclause have complexity $O(size() \ast str.size())$ at worst, although implementations should do better.

Let $F$ be one of find, rfind, find_first_of, find_last_of, find_first_not_of, and find_last_not_of.

1. Each member function of the form
   - constexpr return-type $F$(const charT* s, size_type pos) const;
   - has effects equivalent to: return $F$(basic_string_view(s), pos);

2. Each member function of the form
   - constexpr return-type $F$(const charT* s, size_type pos, size_type n) const;
   - has effects equivalent to: return $F$(basic_string_view(s, n), pos);

3. Each member function of the form
   - constexpr return-type $F$(charT c, size_type pos) const noexcept;
   - has effects equivalent to: return $F$(basic_string_view(addressof(c), 1), pos);

   constexpr size_type find(basic_string_view str, size_type pos = 0) const noexcept;

4. Let xpos be the lowest position, if possible, such that the following conditions hold:

   - pos <= xpos
   - xpos + str.size() <= size()
   - traits::eq(at(xpos + I), str.at(I)) for all elements I of the string referenced by str.

   Effects: Determines xpos.

   Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

5. Let xpos be the highest position, if possible, such that the following conditions hold:

   - xpos <= pos

§ 21.4.2.7 758
7 Effects: Determines xpos.
8 Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_first_of(basic_string_view str, size_type pos = 0) const noexcept;

Let xpos be the lowest position, if possible, such that the following conditions hold:

- pos <= xpos
- xpos < size()
- traits::eq(at(xpos), str.at(I)) for some element I of the string referenced by str.

Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_last_of(basic_string_view str, size_type pos = npos) const noexcept;

Let xpos be the highest position, if possible, such that the following conditions hold:

- xpos <= pos
- xpos < size()
- traits::eq(at(xpos), str.at(I)) for some element I of the string referenced by str.

Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_first_not_of(basic_string_view str, size_type pos = 0) const noexcept;

Let xpos be the lowest position, if possible, such that the following conditions hold:

- pos <= xpos
- xpos < size()
- traits::eq(at(xpos), str.at(I)) for no element I of the string referenced by str.

Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_last_not_of(basic_string_view str, size_type pos = npos) const noexcept;

Let xpos be the highest position, if possible, such that the following conditions hold:

- xpos <= pos
- xpos < size()
- traits::eq(at(xpos), str.at(I)) for no element I of the string referenced by str.

Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

21.4.3 Deduction guide

template<class It, class End>
basic_string_view(It, End) -> basic_string_view<iter_value_t<It>>;

Constraints:
- It satisfies contiguous_iterator.
- End satisfies sized_sentinel_for<It>.

21.4.4 Non-member comparison functions

Let S be basic_string_view<charT, traits>, and sv be an instance of S. Implementations shall provide sufficient additional overloads marked constexpr and noexcept so that an object t with an implicit conversion to S can be compared according to Table 71.

[Example: A sample conforming implementation for operator== would be:
Table 71: Additional basic_string_view comparison overloads  

<table>
<thead>
<tr>
<th>Expression</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>t == sv</td>
<td>S(t) == sv</td>
</tr>
<tr>
<td>sv == t</td>
<td>sv == S(t)</td>
</tr>
<tr>
<td>t != sv</td>
<td>S(t) != sv</td>
</tr>
<tr>
<td>sv != t</td>
<td>sv != S(t)</td>
</tr>
<tr>
<td>t &lt; sv</td>
<td>S(t) &lt; sv</td>
</tr>
<tr>
<td>sv &lt; t</td>
<td>sv &lt; S(t)</td>
</tr>
<tr>
<td>t &gt; sv</td>
<td>S(t) &gt; sv</td>
</tr>
<tr>
<td>sv &gt; t</td>
<td>sv &gt; S(t)</td>
</tr>
<tr>
<td>t &lt;= sv</td>
<td>S(t) &lt;= sv</td>
</tr>
<tr>
<td>sv &lt;= t</td>
<td>sv &lt;= S(t)</td>
</tr>
<tr>
<td>t &gt;= sv</td>
<td>S(t) &gt;= sv</td>

<tr>
<td>sv &gt;= t</td>
<td>sv &gt;= S(t)</td>
</tr>
<tr>
<td>t &lt;=&gt; sv</td>
<td>S(t) &lt;=&gt; sv</td>
</tr>
<tr>
<td>sv &lt;=&gt; t</td>
<td>sv &lt;=&gt; S(t)</td>
</tr>
</tbody>
</table>

```
template<class charT, class traits>  
constexpr bool operator==(basic_string_view<charT, traits> lhs,  
basic_string_view<charT, traits> rhs) noexcept {  
  return lhs.compare(rhs) == 0;  
}  
```  

```
template<class charT, class traits>  
constexpr bool operator==(basic_string_view<charT, traits> lhs,  
type_identity_t<basic_string_view<charT, traits>> rhs) noexcept {  
  return lhs.compare(rhs) == 0;  
}  
```  

— end example]

```
template<class charT, class traits>  
constexpr bool operator==(basic_string_view<charT, traits> lhs,  
basic_string_view<charT, traits> rhs) noexcept;
```  

2 Returns: lhs.compare(rhs) == 0.

```
template<class charT, class traits>  
constexpr see below operator<=>(basic_string_view<charT, traits> lhs,  
basic_string_view<charT, traits> rhs) noexcept;
```  

3 Let R denote the type traits::comparison_category if it exists, otherwise R is weak_ordering.

4 Returns: static_cast<R>(lhs.compare(rhs) <=> 0).

21.4.5 Inserters and extractors  

```
template<class charT, class traits>  
basic_ostream<charT, traits>&  
operator<<(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);
```  

1 Effects: Behaves as a formatted output function (29.7.5.2.1) of os. Forms a character sequence seq, initially consisting of the elements defined by the range [str.begin(), str.end()). Determines padding for seq as described in 29.7.5.2.1. Then inserts seq as if by calling os.rdbuf()->sputn(seq, n), where n is the larger of os.width() and str.size(); then calls os.width(0).

2 Returns: os

21.4.6 Hash support  

```
template<> struct hash<string_view>;  
template<> struct hash<u8string_view>;  
template<> struct hash<u16string_view>;  
template<> struct hash<u32string_view>;
```
template<> struct hash<wstring_view>;

The specialization is enabled (20.14.18). [Note: The hash value of a string view object is equal to the hash value of the corresponding string object (21.3.5). — end note]

21.4.7 Suffix for basic_string_view literals [string.view.literals]

```cpp
constexpr string_view operator"sv(const char* str, size_t len) noexcept; 1
    Returns: string_view{str, len}.

constexpr u8string_view operator"sv(const char8_t* str, size_t len) noexcept; 2
    Returns: u8string_view{str, len}.

constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept; 3
    Returns: u16string_view{str, len}.

constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept; 4
    Returns: u32string_view{str, len}.

constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept; 5
    Returns: wstring_view{str, len}.
```

21.5 Null-terminated sequence utilities [c.strings]

21.5.1 Header <cctype> synopsis [cctype.syn]

```cpp
namespace std {
    int isalnum(int c);
    int isalpha(int c);
    int isblank(int c);
    int iscntrl(int c);
    int isdigit(int c);
    int isgraph(int c);
    int islower(int c);
    int isprint(int c);
    int ispunct(int c);
    int isspace(int c);
    int isupper(int c);
    int isxdigit(int c);
    int tolower(int c);
    int toupper(int c);
}
```

The contents and meaning of the header <cctype> are the same as the C standard library header <ctype.h>.

21.5.2 Header <cwctype> synopsis [cwctype.syn]

```cpp
namespace std {
    using wint_t = see below;
    using wctrans_t = see below;
    using wctype_t = see below;

    int iswalnum(wint_t wc);
    int iswalpha(wint_t wc);
    int iswblank(wint_t wc);
    int iswcntrl(wint_t wc);
    int iswdigit(wint_t wc);
    int iswgraph(wint_t wc);
    int iswlower(wint_t wc);
    int iswprint(wint_t wc);
    int iswpunct(wint_t wc);
    int iswspace(wint_t wc);
    int iswupper(wint_t wc);
    int iswxdigit(wint_t wc);
```

```cpp
int iswctype(wint_t wc, wctype_t desc);
wctype_t wctype(const char* property);
wint_t towlower(wint_t wc);
wint_t toupper(wint_t wc);
wint_t towctrans(wint_t wc, wctrans_t desc);
wctrans_t wctrans(const char* property);
```

#define WEOF see below

1 The contents and meaning of the header `<cwctype>` are the same as the C standard library header `<wctype.h>`.

21.5.3 Header `<cstring` synopsis

```cpp
namespace std {
    using size_t = see 17.2.4;
    using mbstate_t = see below;
    using wint_t = see below;
    namespace std {
        void* memcpy(void* s1, const void* s2, size_t n);
        void* memmove(void* s1, const void* s2, size_t n);
        char* strpcpy(char* s1, const char* s2);
        char* strncpy(char* s1, const char* s2, size_t n);
        char* strcat(char* s1, const char* s2);
        char* strncat(char* s1, const char* s2, size_t n);
        int memcmp(const void* s1, const void* s2, size_t n);
        int strcmp(const char* s1, const char* s2);
        int strcoll(const char* s1, const char* s2);
        int strncmp(const char* s1, const char* s2, size_t n);
        size_t strxfrm(char* s1, const char* s2, size_t n);
        const void* memchr(const void* s, int c, size_t n);
        // see 16.2
        void* memchr(void* s, int c, size_t n);
        // see 16.2
        const char* strchr(const char* s, int c);
        // see 16.2
        char* strchr(char* s, int c);
        // see 16.2
        size_t strcspn(const char* s1, const char* s2);
        const char* strpbrk(const char* s1, const char* s2);
        // see 16.2
        char* strpbrk(char* s1, const char* s2);
        // see 16.2
        const char* strstr(const char* s1, const char* s2);
        char* strstr(char* s1, const char* s2);
        // see 16.2
        size_t strlen(const char* s);
    }
}
```

#define NULL see 17.2.3

1 The contents and meaning of the header `<cstring>` are the same as the C standard library header `<string.h>`.

2 The functions `strerror` and `strtok` are not required to avoid data races (16.5.5.10).

3 The functions `memcpy` and `memmove` are signal-safe (17.13.4). Both functions implicitly create objects (6.7.2) in the destination region of storage immediately prior to copying the sequence of characters to the destination.

4 [Note: The functions `strchr`, `strpbrk`, `strrchr`, `strstr`, and `memchr`, have different signatures in this document, but they have the same behavior as in the C standard library (16.2). — end note]

size_t mbrlen(const char* s, size_t n, mbstate_t* ps);
size_t mbtowc(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbtowcs(wchar_t* dst, const char** src, size_t len, mbstate_t* ps);
size_t wcrtombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);

Effects: These functions have the semantics specified in the C standard library.

Remarks: Calling these functions with an mbstate_t* argument that is a null pointer value may introduce a data race (16.5.5.10) with other calls to the same function with an mbstate_t* argument that is a null pointer value.

§ 21.5.6 764
**ISO C 7.29.6.3**

```c
size_t mbrtoc8(char8_t* pc8, const char* s, size_t n, mbstate_t* ps);
```

**Effects:** If `s` is a null pointer, equivalent to `mbrtoc8(nullptr, "", 1, ps)`. Otherwise, the function inspects at most `n` bytes beginning with the byte pointed to by `s` to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding UTF-8 code units and then, if `pc8` is not a null pointer, stores the value of the first (or only) such code unit in the object pointed to by `pc8`. Subsequent calls will store successive UTF-8 code units without consuming any additional input until all the code units have been stored. If the corresponding Unicode character is U+0000, the resulting state described is the initial conversion state.

**Returns:** The first of the following that applies (given the current conversion state):

- **(8.1)** 0, if the next `n` or fewer bytes complete the multibyte character that corresponds to the U+0000 Unicode character (which is the value stored).
- **(8.2)** between 1 and `n` (inclusive), if the next `n` or fewer bytes complete a valid multibyte character (which is the value stored); the value returned is the number of bytes that complete the multibyte character.
- **(8.3)** `(size_t)(-3)`, if the next character resulting from a previous call has been stored (no bytes from the input have been consumed by this call).
- **(8.4)** `(size_t)(-2)`, if the next `n` bytes contribute to an incomplete (but potentially valid) multibyte character, and all `n` bytes have been processed (no value is stored).
- **(8.5)** `(size_t)(-1)`, if an encoding error occurs, in which case the next `n` or fewer bytes do not contribute to a complete and valid multibyte character (no value is stored); the value of the macro `EILSEQ` is stored in `errno`, and the conversion state is unspecified.

```c
size_t c8rtomb(char* s, char8_t c8, mbstate_t* ps);
```

**Effects:** If `s` is a null pointer, equivalent to `c8rtomb(buf, u8'\0', ps)` where `buf` is an internal buffer. Otherwise, if `c8` completes a sequence of valid UTF-8 code units, determines the number of bytes needed to represent the multibyte character (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by `s`. At most `MB_CUR_MAX` bytes are stored. If the multibyte character is a null character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

**Returns:** The number of bytes stored in the array object (including any shift sequences). If `c8` does not contribute to a sequence of `char8_t` corresponding to a valid multibyte character, the value of the macro `EILSEQ` is stored in `errno`, `(size_t)(-1)` is returned, and the conversion state is unspecified.

**Remarks:** Calls to `c8rtomb` with a null pointer argument for `s` may introduce a data race (16.5.5.10) with other calls to `c8rtomb` with a null pointer argument for `s`.

22 Containers library

22.1 General

1 This Clause describes components that C++ programs may use to organize collections of information.

2 The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 72.

22.2 Container requirements

22.2.1 General container requirements

1 Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

2 All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects. [Example: The copy constructor of type vector<vector<int>> has linear complexity, even though the complexity of copying each contained vector<int> is itself linear. — end example]

3 For the components affected by this subclause that declare an allocator_type, objects stored in these components shall be constructed using the function allocator_traits<allocator_type>::rebind_traits<U>::construct and destroyed using the function allocator_traits<allocator_type>::rebind_traits<U>::destroy (20.10.9.2), where U is either allocator_type::value_type or an internal type used by the container. These functions are called only for the container’s element type, not for internal types used by the container. [Note: This means, for example, that a node-based container might need to construct nodes containing aligned buffers and call construct to place the element into the buffer. — end note]

4 In Tables 73, 74, and 75 X denotes a container class containing objects of type T, a and b denote values of type X, i and j denote values of type (possibly const) X::iterator, u denotes an identifier, r denotes a non-const value of type X, and rv denotes a non-const rvalue of type X.

| a.size()     | size_type            | distance(a.begin(), a.end()) |                                                          | constant     |
| a.max_size() | size_type            | distance(begin(), end()) for the largest possible container |                                                          | constant     |
| a.empty()    | convertible to bool  | a.begin() == a.end()   |                                                          | constant     |

Those entries marked "(Note A)" or "(Note B)" have linear complexity for array and have constant complexity for all other standard containers. [Note: The algorithm equal is defined in Clause 25. — end note]

5 The member function size() returns the number of elements in the container. The number of elements is defined by the rules of constructors, inserts, and erases.

6 begin() returns an iterator referring to the first element in the container. end() returns an iterator which is the past-the-end value for the container. If the container is empty, then begin() == end().

7 In the expressions
   
i == j  
i != j  
i < j  
i <= j  
i >= j  
i > j  
i <=> j  
i - j

where i and j denote objects of a container’s iterator type, either or both may be replaced by an object of the container’s const_iterator type referring to the same element with no change in semantics.

8 Unless otherwise specified, all containers defined in this Clause obtain memory using an allocator (see 16.5.3.5). [Note: In particular, containers and iterators do not store references to allocated elements other than through the allocator’s pointer type, i.e., as objects of type P or pointer_traits<P>::template rebind<unspecified>, where P is allocator_traits<allocator_type>::pointer. — end note] Copy constructors for these container types obtain an allocator by calling allocator_traits<allocator_type>::select_on_container_copy_construction on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a const allocator_type& argument. [Note: If an invocation of a constructor uses the default value of an optional allocator argument, then the allocator type must support value-initialization. — end note] A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment.
or swap(). Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value, allocator_traits<allocator_type>::propagate_on_container_move_assignment::value, or allocator_traits<allocator_type>::propagate_on_container_swap::value is true within the implementation of the corresponding container operation. In all container types defined in this Clause, the member get_allocator() returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

9 The expression a.swap(b), for containers a and b of a standard container type other than array, shall exchange the values of a and b without invoking any move, copy, or swap operations on the individual container elements. Lvalues of any Compare, Pred, or Hash types belonging to a and b shall be swappable and shall be exchanged by calling swap as described in 16.5.3.2. If allocator_traits<allocator_type>::propagate_on_container_swap::value is true, then values of type allocator_type shall be swappable and the allocators of a and b shall also be exchanged by calling swap as described in 16.5.3.2. Otherwise, the allocators shall not be swapped, and the behavior is undefined unless a.get_allocator() == b.get_allocator(). Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value a.end() before the swap will have value b.end() after the swap.

10 If the iterator type of a container belongs to the bidirectional or random access iterator categories (23.3), the container is called reversible and meets the additional requirements in Table 74.

</tr>
</tbody>
</table>

11 Unless otherwise specified (see 22.2.6.1, 22.2.7.1, 22.3.8.4, and 22.3.11.5) all container types defined in this Clause meet the following additional requirements:

11.1 if an exception is thrown by an insert() or emplace() function while inserting a single element, that function has no effects.

11.2 if an exception is thrown by a push_back(), push_front(), emplace_back(), or emplace_front() function, that function has no effects.

11.3 no erase(), clear(), pop_back() or pop_front() function throws an exception.

11.4 no copy constructor or assignment operator of a returned iterator throws an exception.

11.5 no swap() function throws an exception.

11.6 no swap() function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped. [Note: The end() iterator does not refer to any element, so it may be invalidated. — end note]

12 Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

13 A contiguous container is a container whose member types iterator and const_iterator meet the Cpp17RandomAccessIterator requirements (23.3.5.6) and model contiguous_iterator (23.3.4.14).
Table 75 lists operations that are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics described in Table 75 unless otherwise stated. If the iterators passed to lexicographical_compare_three_way meet the constexpr iterator requirements (23.3.1) then the operations described in Table 75 are implemented by constexpr functions.

<table>
<thead>
<tr>

<td>Preconditions: Either &lt;= is defined for values of type (possibly const) T, or &lt; is defined for values of type (possibly const) T and &lt; is a total ordering relationship.</td>
<td>linear</td>
</tr>
</tbody>
</table>

[Note: The algorithm lexicographical_compare_three_way is defined in Clause 25. — end note]

All of the containers defined in this Clause and in 21.3.2 except array meet the additional requirements of an allocator-aware container, as described in Table 76.

Given an allocator type A and a container type X having a value_type identical to T and an allocator_type identical to allocator_traits<A>::rebind_alloc<T> and given an lvalue m of type A, a pointer p of type T*, an expression v of type (possibly const) T, and an rvalue rv of type T, the following terms are defined. If X is not allocator-aware, the terms below are defined as if A were allocator<T> — no allocator object needs to be created and user specializations of allocator<T> are not instantiated:

15

- T is Cpp17DefaultInsertable into X means that the following expression is well-formed:
  
  `allocator_traits<A>::construct(m, p)`

- An element of X is default-inserted if it is initialized by evaluation of the expression
  
  `allocator_traits<A>::construct(m, p)`

  where p is the address of the uninitialized storage for the element allocated within X.

- T is Cpp17MoveInsertable into X means that the following expression is well-formed:
  
  `allocator_traits<A>::construct(m, p, rv)`

  and its evaluation causes the following postcondition to hold: The value of *p is equivalent to the value of rv before the evaluation. [Note: rv remains a valid object. Its state is unspecified — end note]

- T is Cpp17CopyInsertable into X means that, in addition to T being Cpp17MoveInsertable into X, the following expression is well-formed:
  
  `allocator_traits<A>::construct(m, p, v)`

  and its evaluation causes the following postcondition to hold: The value of v is unchanged and is equivalent to *p.

- T is Cpp17EmplaceConstructible into X from args, for zero or more arguments args, means that the following expression is well-formed:
  
  `allocator_traits<A>::construct(m, p, args)`

- T is Cpp17Erasable from X means that the following expression is well-formed:
  
  `allocator_traits<A>::destroy(m, p)`

  [Note: A container calls allocator_traits<A>::construct(m, p, args) to construct an element at p using args, with m == get_allocator(). The default construct in allocator will call ::new((void*)p) T(args), but specialized allocators may choose a different definition. — end note]

In Table 76, X denotes an allocator-aware container class with a value_type of T using allocator of type A, u denotes a variable, a and b denote non-const lvalues of type X, t denotes an lvalue or a const rvalue of type X, rv denotes a non-const rvalue of type X, and m is a value of type A.

</tbody>
</table>

\[17\] The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to
which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type A shall not qualify as an allocator unless it meets both of the following conditions:

1. The qualified-id A::value_type is valid and denotes a type (13.10.2).
2. The expression declval<A&>().allocate(size_t{}) is well-formed when treated as an unevaluated operand.

22.2.2 Container data races

For purposes of avoiding data races (16.5.5.10), implementations shall consider the following functions to be const: begin, end, rbegin, rend, front, back, data, find, lower_bound, upper_bound, equal_range, at and, except in associative or unordered associative containers, operator[].

Notwithstanding 16.5.5.10, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting vector<bool>, are modified concurrently.

[Note: For a vector<int> x with a size greater than one, x[1] = 5 and *x.begin() = 10 can be executed concurrently without a data race, but x[0] = 5 and *x.begin() = 10 executed concurrently may result in a data race. As an exception to the general rule, for a vector<bool> y, y[0] = true may race with y[1] = true. — end note]

22.2.3 Sequence containers

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: vector, forward_list, list, and deque. In addition, array is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as stacks or queues, out of the basic sequence container kinds (or out of other kinds of sequence containers that the user might define).

[Note: The sequence containers offer the programmer different complexity trade-offs and should be used accordingly. vector is the type of sequence container that should be used by default. array should be used when the container has a fixed size known during translation. list or forward_list should be used when there are frequent insertions and deletions from the middle of the sequence. deque is the data structure of choice when most insertions and deletions take place at the beginning or at the end of the sequence. When choosing a container, remember vector is best; leave a comment to explain if you choose from the rest! — end note]

In Tables 77 and 78, X denotes a sequence container class, a denotes a value of type X containing elements of type T, u denotes the name of a variable being declared, A denotes X::allocator_type if the qualified-id X::allocator_type is valid and denotes a type (13.10.2) and allocator<T> if it doesn’t, i and j denote iterators that meet the Cpp17InputIterator requirements and refer to elements implicitly convertible to value_type, [i, j) denotes a valid range, il designates an object of type initializer_list<value_type>, n denotes a value of type X::size_type, p denotes a valid constant iterator to a, q denotes a valid dereferenceable constant iterator to a, [q1, q2) denotes a valid range of constant iterators in a, t denotes an lvalue or a const rvalue of X::value_type, and rv denotes a non-const rvalue of X::value_type. Args denotes a template parameter pack; args denotes a function parameter pack with the pattern Args&&.

The complexities of the expressions are sequence dependent.

</tr>
</tbody>
</table>

5 The iterator returned from `a.insert(p, t)` points to the copy of t inserted into a.

6 The iterator returned from `a.insert(p, rv)` points to the copy of rv inserted into a.

7 The iterator returned from `a.insert(p, n, t)` points to the copy of the first element inserted into a, or p if n == 0.

8 The iterator returned from `a.insert(p, i, j)` points to the copy of the first element inserted into a, or p if i == j.

9 The iterator returned from `a.insert(p, il)` points to the copy of the first element inserted into a, or p if il is empty.

10 The iterator returned from `a.emplace(p, args)` points to the new element constructed from args into a.

11 The iterator returned from `a.erase(q)` points to the element immediately following q prior to the element being erased. If no such element exists, a.end() is returned.

12 The iterator returned by `a.erase(q1, q2)` points to the element pointed to by q2 prior to any elements being erased. If no such element exists, a.end() is returned.

13 For every sequence container defined in this Clause and in Clause 21:

13.1 — If the constructor

```
template<class InputIterator>
X(InputIterator first, InputIterator last,
  const allocator_type& alloc = allocator_type());
```

is called with a type InputIterator that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

13.2 — If the member functions of the forms:

```
template<class InputIterator>
    return-type F(const_iterator p,
                   InputIterator first, InputIterator last); // such as insert
```
A deduction guide for a sequence container shall not participate in overload resolution if it has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter, or if it has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

14 Table 78 lists operations that are provided for some types of sequence containers but not others. An implementation shall provide these operations for all container types shown in the “container” column, and shall implement them so as to take amortized constant time.

The member function at() provides bounds-checked access to container elements. at() throws out_of_range if n >= a.size().

22.2.4 Node handles

22.2.4.1 Overview

A node handle is an object that accepts ownership of a single element from an associative container (22.2.6) or an unordered associative container (22.2.7). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 79.

Table 79: Container types with compatible nodes

If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.

Class node-handle is for exposition only.

If a user-defined specialization of pair exists for pair<const Key, T> or pair<Key, T>, where Key is the container’s key_type and T is the container’s mapped_type, the behavior of operations involving node handles is undefined.

```
template<unspeifed>
class node-handle {
  public:
    // These type declarations are described in Tables 80 and 81.
    using value_type = see below;  // not present for map containers
    using key_type = see below;   // not present for set containers
    using mapped_type = see below; // not present for set containers
    using allocator_type = see below;

  private:
    using container_node_type = unspecified;
    using ator_traits = allocator_traits<allocator_type>;

    typename ator_traits::template rebind_traits<container_node_type>::pointer ptr_;
    optional<allocator_type> alloc;

  § 22.2.4.1 776
public:

// 22.2.4.2, constructors, copy, and assignment
constexpr node-handle() noexcept : ptr_(), alloc_() {}
node-handle(node-handle&&) noexcept;
node-handle& operator=(node-handle&&);

// 22.2.4.3, destructor
~node-handle();

// 22.2.4.4, observers
value_type& value() const; // not present for map containers
key_type& key() const; // not present for set containers
mapped_type& mapped() const; // not present for set containers
allocator_type get_allocator() const;
explicit operator bool() const noexcept;
[[nodiscard]] bool empty() const noexcept;

// 22.2.4.5, modifiers
void swap(node-handle&);

22.2.4.2 Constructors, copy, and assignment

node-handle(node-handle&& nh) noexcept;

Effects: Constructs a node-handle object initializing ptr_ with nh.ptr_. Move constructs alloc_ with nh.alloc_. Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

node-handle& operator=(node-handle&& nh);

Preconditions: Either !alloc_ or ator_traits::propagate_on_container_move_assignment::value is true, or alloc_ == nh.alloc_.

Effects:
(3.1) — If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::template rebind_traits<container_node_type>::deallocate.
(3.2) — Assigns nh.ptr_to ptr_.
(3.3) — If !alloc_ or ator_traits::propagate_on_container_move_assignment::value is true, move assigns nh.alloc_to alloc_.
(3.4) — Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

Returns: *this.

Throws: Nothing.

22.2.4.3 Destructor

~node-handle();

Effects: If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::template rebind_traits<container_node_type>::deallocate.

22.2.4.4 Observers

value_type& value() const;

Preconditions: empty() == false.
Returns: A reference to the value_type subobject in the container_node_type object pointed to by ptr_.

Throws: Nothing.

key_type& key() const;
Preconditions: empty() == false.
Returns: A non-const reference to the key_type member of the value_type subobject in the container_node_type object pointed to by ptr_.
Throws: Nothing.
Remarks: Modifying the key through the returned reference is permitted.

mapped_type& mapped() const;
Preconditions: empty() == false.
Returns: A reference to the mapped_type member of the value_type subobject in the container_node_type object pointed to by ptr_.
Throws: Nothing.

allocator_type get_allocator() const;
Preconditions: empty() == false.
Returns: *alloc_.
Throws: Nothing.

explicit operator bool() const noexcept;
Returns: ptr_ != nullptr.

[[nodiscard]] bool empty() const noexcept;
Returns: ptr_ == nullptr.

22.2.4.5 Modifiers [container.node.modifiers]
void swap(node-handle nh)
noexcept(ator_traits::propagate_on_container_swap::value ||
ator_traits::is_always_equal::value);
Preconditions: !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true, or alloc_ == nh.alloc_.
Effects: Calls swap(ptr_, nh.ptr_). If !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true calls swap(alloc_, nh.alloc_).

22.2.5 Insert return type [container.insert.return]
The associative containers with unique keys and the unordered containers with unique keys have a member function insert that returns a nested type insert_return_type. That return type is a specialization of the template specified in this subclause.

template<class Iterator, class NodeType>
struct insert_return_type
{
    Iterator position;
    bool inserted;
    NodeType node;
};
The name insert_return_type is exposition only. insert_return_type has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

22.2.6 Associative containers [associative.reqmts]
Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: set, multiset, map and multimap.
Each associative container is parameterized on Key and an ordering relation Compare that induces a strict weak ordering (25.8) on elements of Key. In addition, map and multimap associate an arbitrary mapped type $T$ with the Key. The object of type Compare is called the comparison object of a container.

The phrase "equivalence of keys" means the equivalence relation imposed by the comparison object. That is, two keys $k_1$ and $k_2$ are considered to be equivalent if for the comparison object $\text{comp}$, $\text{comp}(k_1, k_2) == \text{false} \&\& \text{comp}(k_2, k_1) == \text{false}$. [Note: This is not necessarily the same as the result of $k_1 == k_2$. — end note] For any two keys $k_1$ and $k_2$ in the same container, calling $\text{comp}(k_1, k_2)$ shall always return the same value.

An associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. The set and map classes support unique keys; the multiset and multimap classes support equivalent keys. For multiset and multimap, insert, emplace, and erase preserve the relative ordering of equivalent elements.

For set and multiset, the value type is the same as the key type. For map and multimap, it is equal to pair<const Key, $T$>.

iterator of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both iterator and const_iterator are constant iterators. It is unspecified whether or not iterator and const_iterator are the same type. [Note: iterator and const_iterator have identical semantics in this case; and iterator is convertible to const_iterator. Users can avoid violating the one-definition rule by always using const_iterator in their function parameter lists. — end note]

The associative containers meet all the requirements of Allocator-aware containers (22.2.1), except that for map and multimap, the requirements placed on value_type in Table 76 apply instead to key_type and mapped_type. [Note: For example, in some cases key_type and mapped_type are required to be $\text{Cpp17CopyAssignable}$ even though the associated value_type, pair<const key_type, mapped_type>, is not $\text{Cpp17CopyAssignable}$. — end note]

In Table 80, $X$ denotes an associative container class, $a_2$ denotes a value of type $X$, $a_2$ denotes a value of a type with nodes compatible with type $X$ (Table 79), $b$ denotes a possibly const value of type $X$, $u$ denotes the name of a variable being declared, $\text{a\_uniq}$ denotes a value of type $X$ when $X$ supports unique keys, $\text{a\_eq}$ denotes a value of type $X$ when $X$ supports multiple keys, a_a Tran denotes a possibly const value of type $X$ when the qualified-id $X::\text{key\_compare}\text{::is\_transparent}$ is valid and denotes a type (13.10.2), $i$ and $j$ meet the $\text{Cpp17InputIterator}$ requirements and refer to elements implicitly convertible to value_type, $[i, j)$ denotes a valid range, $p$ denotes a valid constant iterator to $a$, $q$ denotes a valid dereferenceable constant iterator to $a$, $r$ denotes a valid dereferenceable iterator to $a$, $[q_1, q_2)$ denotes a valid range of constant iterators in $a$, $i_l$ designates an object of type $\text{vector<}}$list$<$value_type$>$, $t$ denotes a value of type $X::\text{value\_type}$, $k$ denotes a value of type $X::\text{key\_type}$ and $c$ denotes a possibly const value of type $X::\text{key\_compare}$ $k_1$ is a value such that $a$ is partitioned (25.8) with respect to $c(r, k_1)$, with $r$ the key value of $e$ and $e$ in $a$; $k_2$ is a value such that $a$ is partitioned with respect to $c(ku, r)$, $ku$ is a value such that $a$ is partitioned with respect to $c(r, ku)$ and $!c(ke, r)$, with $c(r, ku)$ implying $!c(ke, r)$. $a$ denotes the storage allocator used by $X$, if any, or allocator$<X::\text{value\_type}>$ otherwise, $m$ denotes an allocator of a type convertible to $a$, and $nh$ denotes a non-const rvalue of type $X::\text{node\_type}$.

</tr>
</tbody>
</table>

9 The `insert` and `emplace` members shall not affect the validity of iterators and references to the container, and the `erase` members shall invalidate only iterators and references to the erased elements.

10 The `extract` members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a `node_type` is undefined behavior. References and pointers to an element obtained while it is owned by a `node_type` are invalidated if the element is successfully inserted.

11 The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators i and j such that distance from i to j is positive, the following condition holds:
   
   value_comp(*j, *i) == false

12 For associative containers with unique keys the stronger condition holds:
   
   value_comp(*i, *j) != false

13 When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, through either a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

14 The member function templates `find`, `count`, `contains`, `lower_bound`, `upper_bound`, and `equal_range` shall not participate in overload resolution unless the `qualified-id` `Compare::is_transparent` is valid and denotes a type (13.10.2).
A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

- It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.
- It has a `Compare` template parameter and a type that qualifies as an allocator is deduced for that parameter.

### 22.2.6.1 Exception safety guarantees

For associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container’s `Compare` object (if any).

For associative containers, if an exception is thrown by any operation from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

For associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container’s `Compare` object (if any).

### 22.2.7 Unordered associative containers

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: `unordered_set`, `unordered_map`, `unordered_multiset`, and `unordered_multimap`.

Unordered associative containers conform to the requirements for Containers (22.2), except that the expressions `a == b` and `a != b` have different semantics than for the other container types.

Each unordered associative container is parameterized by `Key`, by a function object type `Hash` that meets the `Cpp17Hash` requirements (16.5.3.4) and acts as a hash function for argument values of type `Key`, and by a binary predicate `Pred` that induces an equivalence relation on values of type `Key`. Additionally, `unordered_map` and `unordered_multimap` associate an arbitrary `mapped type` `T` with the `Key`.

The container’s object of type `Hash` — denoted by `hash` — is called the `hash function` of the container. The container’s object of type `Pred` — denoted by `pred` — is called the `key equality predicate` of the container.

Two values `k1` and `k2` are considered equivalent if the container’s key equality predicate `pred(k1, k2)` is valid and returns `true` when passed those values. If `k1` and `k2` are equivalent, the container’s hash function shall return the same value for both. [Note: Thus, when an unordered associative container is instantiated with a non-default `Pred` parameter it usually needs a non-default `Hash` parameter as well. — end note] For any two keys `k1` and `k2` in the same container, calling `pred(k1, k2)` shall always return the same value. For any key `k` in a container, calling `hash(k)` shall always return the same value.

An unordered associative container supports `unique keys` if it may contain at most one element for each key. Otherwise, it supports `equivalent keys`. `unordered_set` and `unordered_map` support unique keys. `unordered_multiset` and `unordered_multimap` support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into `equivalent-key groups` such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

For `unordered_set` and `unordered_multiset` the value type is the same as the key type. For `unordered_map` and `unordered_multimap` it is `pair<const Key, T>`.

For unordered containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type. [Note: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — end note]

The elements of an unordered associative container are organized into `buckets`. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For `unordered_multiset` and `unordered_multimap`, rehashing preserves the relative ordering of equivalent elements.
The unordered associative containers meet all the requirements of Allocator-aware containers (22.2.1), except that for unordered_map and unordered_multimap, the requirements placed on value_type in Table 76 apply instead to key_type and mapped_type. [Note: For example, key_type and mapped_type are sometimes required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]

In Table 81:

- X denotes an unordered associative container class,
- a denotes a value of type X,
- a2 denotes a value of a type with nodes compatible with type X (Table 79),
- b denotes a possibly const value of type X,
- a_uniq denotes a value of type X when X supports unique keys,
- a_eq denotes a value of type X when X supports equivalent keys,
- a_tran denotes a possibly const value of type X when the qualified-ids X::key_equal::is_transparent and X::hasher::is_transparent are both valid and denote types (13.10.2),
- i and j denote input iterators that refer to value_type,
- [i, j) denotes a valid range,
- p and q2 denote valid constant iterators to a,
- q and q1 denote valid dereferenceable constant iterators to a,
- r denotes a valid dereferenceable iterator to a,
- [q1, q2) denotes a valid range in a,
- il denotes a value of type initializer_list<value_type>,
- t denotes a value of type X::value_type,
- k denotes a value of type key_type,
- hf denotes a possibly const value of type hasher,
- eq denotes a possibly const value of type key_equal,
- ke is a value such that
  - eq(r1, ke) == eq(ke, r1)
  - hf(r1) == hf(ke) if eq(r1, ke) is true, and
  - (eq(r1, ke) && eq(r1, r2)) == eq(r2, ke)
  where r1 and r2 are keys of elements in a_tran,
- n denotes a value of type size_type,
- z denotes a value of type float, and
- nh denotes a non-const rvalue of type X::node_type.

| `a_eq.emplace(args)` | iterator    | **Preconditions**: `value_type` is `Cpp17EmplaceConstructible` into `X` from `args`.  
**Effects**: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...)` and returns the iterator pointing to the newly inserted element. | Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a_eq.size())$. |
| `a.emplace_hint(p, args)` | iterator | **Preconditions**: `value_type` is `Cpp17EmplaceConstructible` into `X` from `args`.  
**Effects**: Equivalent to `a.emplace(std::forward<Args>(args)...)`. Return value is an iterator pointing to the element with the key equivalent to the newly inserted element. The `const_iterator p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint. | Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a.size())$. |
| `a_uniq.insert(t)`  | `pair<iterator, bool>` | **Preconditions**: If `t` is a non-constant value, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.  
**Effects**: Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`. The `bool` component of the returned pair indicates whether the insertion takes place, and the `iterator` component points to the element with key equivalent to the key of `t`. | Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a_uniq.size())$. |
| `a_eq.insert(t)`    | iterator    | **Preconditions**: If `t` is a non-constant value, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.  
**Effects**: Inserts `t`, and returns an iterator pointing to the newly inserted element. | Average case $\mathcal{O}(1)$, worst case $\mathcal{O}(a_eq.size())$. |

12 Two unordered containers a and b compare equal if a.size() == b.size() and, for every equivalent-key group [Ea1, Ea2) obtained from a.equal_range(Ea1), there exists an equivalent-key group (Eb1, Eb2) obtained from b.equal_range(Ea1), such that is_permutation(Ea1, Ea2, Eb1, Eb2) returns true. For unordered_set and unordered_map, the complexity of operator== (i.e., the number of calls to the == operator of the value_type, to the predicate returned by key_eq(), and to the hasher returned by hash_function()) is proportional to N in the average case and to \(N^2\) in the worst case, where \(N\) is a.size(). For unordered_multiset and unordered_multimap, the complexity of operator== is proportional to \(\sum E_i^2\) in the average case and to \(N^2\) in the worst case, where \(N\) is a.size(), and \(E_i\) is the size of the \(i^{th}\) equivalent-key group in a. However, if the respective elements of each corresponding pair of equivalent-key groups \(E_{a_i}\) and \(E_{b_i}\) are arranged in the same order (as is commonly the case, e.g., if a and b are unmodified copies of the same container), then the average-case complexity for unordered_multiset and unordered_multimap becomes proportional to \(N\) (but worst-case complexity remains \(O(N^2)\), e.g., for a pathologically bad hash function). The behavior of a program that uses operator== or operator!= on unordered containers is undefined unless the Pred function object has the same behavior for both containers and the equality comparison function for Key is a refinement\(^{224}\) of the partition into equivalent-key groups produced by Pred.

13 The iterator types iterator and const_iterator of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both iterator and const_iterator are constant iterators.

14 The insert and emplace members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The erase members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

15 The insert and emplace members shall not affect the validity of iterators if \((N+n) <= z * B\), where \(N\) is the number of elements in the container prior to the insert operation, \(n\) is the number of elements inserted, \(B\) is the container’s bucket count, and \(z\) is the container’s maximum load factor.

16 The extract members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

17 The member function templates find, count, equal_range, and contains shall not participate in overload resolution unless the qualified-ids Pred::is_transparent and Hash::is_transparent are both valid and denote types (13.10.2).

18 A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

18.1 It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

18.2 It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.

18.3 It has a Hash template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.

18.4 It has a Pred template parameter and a type that qualifies as an allocator is deduced for that parameter.

\(^{224}\) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.
22.2.7.1 Exception safety guarantees

For unordered associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container’s Hash or Pred object (if any).

For unordered associative containers, if an exception is thrown by any operation other than the container’s hash function from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

For unordered associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container’s Hash or Pred object (if any).

For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container’s hash function or comparison function, the `rehash()` function has no effect.

22.3 Sequence containers

22.3.1 In general

The headers `<array>` (22.3.2), `<deque>` (22.3.3), `<forward_list>` (22.3.4), `<list>` (22.3.5), and `<vector>` (22.3.6) define class templates that meet the requirements for sequence containers.

The following exposition-only alias template may appear in deduction guides for sequence containers:

```cpp
template<class InputIterator>
using iter_value_type = typename iterator_traits<InputIterator>::value_type; // exposition only
```

22.3.2 Header `<array>` synopsis

```cpp
#include <compare>     // see 17.11.1
#include <initializer_list>  // see 17.10.1

namespace std {
    // 22.3.7, class template array
    template<class T, size_t N> struct array;
    template<class T, size_t N>
    constexpr bool operator==(const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
    constexpr synth_three_way_result<T>
        operator<=>(const array<T, N>& x, const array<T, N>& y);

    // 22.3.7.4, specialized algorithms
    template<class T, size_t N>
    constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

    // 22.3.7.6, array creation functions
    template<class T, size_t N>
    constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
    template<class T, size_t N>
    constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);

    // 22.3.7.7, tuple interface
    template<class T> struct tuple_size;
    template<size_t I, class T> struct tuple_element;
    template<size_t I, class T, size_t N>
    struct tuple_size<array<T, N>>;
    template<size_t I, class T, size_t N>
    struct tuple_element<I, array<T, N>>;
    template<size_t I, class T, size_t N>
    constexpr T& get(array<T, N>&) noexcept;
    template<size_t I, class T, size_t N>
    constexpr T&& get(array<T, N>&&) noexcept;
    template<size_t I, class T, size_t N>
    constexpr const T& get(const array<T, N>&) noexcept;
    template<size_t I, class T, size_t N>
    constexpr const T&& get(const array<T, N>&&) noexcept;
}
```
22.3.3 Header <deque> synopsis

```cpp
#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.1

namespace std {
    // 22.3.8, class template deque
    template<class T, class Allocator = allocator<T>> class deque;

    template<class T, class Allocator>
    bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

    template<class T, class Allocator>
    synth-three-way-result<T> operator<=>(const deque<T, Allocator>& x,
                                           const deque<T, Allocator>& y);

    template<class T, class Allocator>
    void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

    template<class T, class Allocator, class U>
    typename deque<T, Allocator>::size_type
    erase(deque<T, Allocator>& x, const U& value);

    template<class T, class Allocator, class Predicate>
    typename deque<T, Allocator>::size_type
    erase_if(deque<T, Allocator>& c, Predicate pred);

    namespace pmr {
        template<class T>
        using deque = std::deque<T, polymorphic_allocator<T>>;
    }
}
```

22.3.4 Header <forward_list> synopsis

```cpp
#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.1

namespace std {
    // 22.3.9, class template forward_list
    template<class T, class Allocator = allocator<T>> class forward_list;

    template<class T, class Allocator>
    bool operator==(const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);

    template<class T, class Allocator>
    synth-three-way-result<T> operator<=>(const forward_list<T, Allocator>& x,
                                           const forward_list<T, Allocator>& y);

    template<class T, class Allocator>
    void swap(forward_list<T, Allocator>& x, forward_list<T, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

    template<class T, class Allocator, class U>
    typename forward_list<T, Allocator>::size_type
    erase(forward_list<T, Allocator>& x, const U& value);

    template<class T, class Allocator, class Predicate>
    typename forward_list<T, Allocator>::size_type
    erase_if(forward_list<T, Allocator>& c, Predicate pred);

    namespace pmr {
        template<class T>
        using forward_list = std::forward_list<T, polymorphic_allocator<T>>;
    }
}
```
22.3.5 Header <list> synopsis

```cpp
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.1

namespace std {
  // 22.3.10, class template list
  template<class T, class Allocator = allocator<T>> class list;

  template<class T, class Allocator>
  bool operator==(const list<T, Allocator>& x, const list<T, Allocator>& y);

  template<class T, class Allocator>
  synth-three-way-result<T> operator<=>(const list<T, Allocator>& x,
                                          const list<T, Allocator>& y);

  template<class T, class Allocator>
  void swap(list<T, Allocator>& x, list<T, Allocator>& y)
             noexcept(noexcept(x.swap(y)));

  template<class T, class Allocator, class U>
  typename list<T, Allocator>::size_type
  erase(list<T, Allocator>& c, const U& value);

  template<class T, class Allocator, class Predicate>
  typename list<T, Allocator>::size_type

    template<class T>
        using vector = std::vector<T, polymorphic_allocator<T>>;
}

22.3.7 Class template array

22.3.7.1 Overview

1 The header `<array>` defines a class template for storing fixed-size sequences of objects. An array is a contiguous container (22.2.1). An instance of array<T, N> stores N elements of type T, so that size() == N is an invariant.

2 An array is an aggregate (9.4.1) that can be list-initialized with up to N elements whose types are convertible to T.

3 An array meets all of the requirements of a container and of a reversible container (22.2), except that a default constructed array object is not empty and that swap does not have constant complexity. An array meets some of the requirements of a sequence container (22.2.3). Descriptions are provided here only for operations on array that are not described in one of these tables and for operations where there is additional semantic information.

4 array<T, N> is a structural type (13.2) if T is a structural type. Two values a1 and a2 of type array<T, N> are template-argument-equivalent (13.6) if and only if each pair of corresponding elements in a1 and a2 are template-argument-equivalent.

5 The types iterator and const_iterator meet the constexpr iterator requirements (23.3.1).

namespace std {
    template<class T, size_t N>
        struct array {
            // types
            using value_type = T;
            using pointer = T*;
            using const_pointer = const T*;
            using reference = T&;
            using const_reference = const T&;
            using size_type = size_t;
            using difference_type = ptrdiff_t;
            using iterator = implementation-defined; // see 22.2
            using const_iterator = implementation-defined; // see 22.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;
            // no explicit construct/copy/destroy for aggregate type
            constexpr void fill(const T& u);
            constexpr void swap(array&) noexcept(is_nothrow_swappable_v<T>);
            // iterators
            constexpr iterator begin() noexcept;
            constexpr const_iterator begin() const noexcept;
            constexpr iterator end() noexcept;
            constexpr const_iterator end() const noexcept;
            constexpr reverse_iterator rbegin() noexcept;
            constexpr const_reverse_iterator rbegin() const noexcept;
            constexpr reverse_iterator rend() noexcept;
            constexpr const_reverse_iterator rend() const noexcept;
            constexpr const_iterator cbegin() const noexcept;
            constexpr const_iterator cend() const noexcept;
            constexpr const_reverse_iterator crbegin() const noexcept;
            constexpr const_reverse_iterator crend() const noexcept;
            // capacity
            [[nodiscard]] constexpr bool empty() const noexcept;
            constexpr size_type size() const noexcept;
            constexpr size_type max_size() const noexcept;
        }
}

§ 22.3.7.1 801
22.3.7.2 Constructors, copy, and assignment

The conditions for an aggregate (9.4.1) shall be met. Class array relies on the implicitly-declared special member functions (11.4.4.1, 11.4.6, and 11.4.4.2) to conform to the container requirements table in 22.2. In addition to the requirements specified in the container requirements table, the implicit move constructor and move assignment operator for array require that \( T \) be `Cpp17MoveConstructible` or `Cpp17MoveAssignable`, respectively.

```
template<class T, class... U>
array(T, U...) -> array<T, 1 + sizeof...(U)>
```

Mandates: `(is_same_v<T, U> && ...) is true`.

22.3.7.3 Member functions

```
constexpr size_type size() const noexcept;

Returns: \( N \).
```

```
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

Returns: A pointer such that \([\text{data}(), \text{data}() + \text{size}()]\) is a valid range. For a non-empty array, \( \text{data}() == \text{addressof(front())} \).
```

```
constexpr void fill(const T& u);

Effects: As if by `fill_n(begin(), N, u)`.
```

```
constexpr void swap(array& y) noexcept(noexcept(x.swap(y)));

Effects: Equivalent to `swap_ranges(begin(), end(), y.begin())`.
```

[Note: Unlike the `swap` function for other containers, `array::swap` takes linear time, may exit via an exception, and does not cause iterators to become associated with the other container. — end note]

22.3.7.4 Specialized algorithms

```
template<class T, size_t N>
constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: \( N == 0 \) or `is_swappable_v<T>` is true.

Effects: As if by `x.swap(y)`.

Complexity: Linear in \( N \).

22.3.7.5 Zero-sized arrays

```
array shall provide support for the special case \( N == 0 \).
```

In the case that \( N == 0 \), `begin() == end() == unique value`. The return value of `data()` is unspecified.

The effect of calling `front()` or `back()` for a zero-sized array is undefined.

Member function `swap()` shall have a non-throwing exception specification.
22.3.7.6 Array creation functions

```cpp
template<class T, size_t N>
constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
1
Mandates: is_array_v<T> is false and is_constructible_v<T, T&> is true.
2
Preconditions: T meets the Cpp17CopyConstructible requirements.
3
Returns: {{ a[0], ..., a[N - 1] }}.
```

```cpp
template<class T, size_t N>
constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);
4
Mandates: is_array_v<T> is false and is_move_constructible_v<T> is true.
5
Preconditions: T meets the Cpp17MoveConstructible requirements.
6
Returns: {{ std::move(a[0]), ..., std::move(a[N - 1]) }}.
```

22.3.7.7 Tuple interface

```cpp
template<class T, size_t N>
struct tuple_size<array<T, N>> : integral_constant<size_t, N> { };
1
```

```cpp
template<size_t I, class T, size_t N>
struct tuple_element<I, array<T, N>> {
    using type = T;
1
};
```

```cpp
template<size_t I, class T, size_t N>
constexpr T& get(array<T, N>& a) noexcept;
2
```

```cpp
template<size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&& a) noexcept;
3
```

```cpp
template<size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>& a) noexcept;
4
```

```cpp
template<size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&& a) noexcept;
5
```

22.3.8 Class template deque

22.3.8.1 Overview

A deque is a sequence container that supports random access iterators (23.3.5.6). In addition, it supports constant
time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a
deque is especially optimized for pushing and popping elements at the beginning and end. Storage management is
handled automatically.

A deque meets all of the requirements of a container, of a reversible container (given in tables in 22.2), of a sequence
container, including the optional sequence container requirements (22.2.3), and of an allocator-aware container
(Table 76). Descriptions are provided here only for operations on deque that are not described in one of these tables
or for operations where there is additional semantic information.

```cpp
namespace std {
    template<class T, class Allocator = allocator<T>>
    class deque {
public:
    // types
    using value_type = T;
    using allocator_type = Allocator;
    using pointer = typename allocator_traits<Allocator>::pointer;
    using const_pointer = typename allocator_traits<Allocator>::const_pointer;
    using reference = value_type&;
    using const_reference = const value_type&;
    using size_type = implementation_defined; // see 222
    using difference_type = implementation_defined; // see 222
```
using iterator = implementation-defined; // see 22.2
using const_iterator = implementation-defined; // see 22.2
using reverse_iterator = std::reverse_iterator<iterator>;
using const_reverse_iterator = std::reverse_iterator<const_iterator>;

// 22.3.8.2, construct/copy/destroy
deque() : deque(Allocator()) { }
explicit deque(const Allocator&);
explicit deque(size_type n, const Allocator& = Allocator());
deque(size_type n, const T& value, const Allocator& = Allocator());
template<class InputIterator>
deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
deque(const deque& x);
deque(deque&);
deque(const deque& x, const Allocator&);
deque(deque&, const Allocator&);
deque(initializer_list<T>, const Allocator& = Allocator());

~deque();
deque& operator=(const deque& x);
deque& operator=(deque& x);
    noexcept(allocation_traits<Allocator>::is_always_equal::value);
deque& operator=(initializer_list<T>);
template<class InputIterator>
void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// iterators
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 22.3.8.3, capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& t);
void shrink_to_fit();

// element access
reference operator[](size_type n);
const_reference operator[](size_type n) const;
reference at(size_type n);
const_reference at(size_type n) const;
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 22.3.8.4, modifiers
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);

void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

void pop_front();
void pop_back();

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(deque&);
noexcept(allocator_traits<Allocator>::is_always_equal::value);
void clear() noexcept;

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
deque(InputIterator, InputIterator, Allocator = Allocator())
-> deque<iter-value-type<InputIterator>>, Allocator>;

// swap
template<class T, class Allocator>
void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)
noexcept(noexcept(x.swap(y)));

22.3.8.2 Constructors, copy, and assignment [deque.cons]

explicit deque(const Allocator&);

Effects: Constructs an empty deque, using the specified allocator.
Complexity: Constant.

explicit deque(size_type n, const Allocator& = Allocator());

Preconditions: T is Cpp17DefaultInsertable into *this.
Effects: Constructs a deque with n default-inserted elements using the specified allocator.
Complexity: Linear in n.

deque(size_type n, const T& value, const Allocator& = Allocator());

Preconditions: T is Cpp17CopyInsertable into *this.
Effects: Constructs a deque with n copies of value, using the specified allocator.
Complexity: Linear in n.

template<class InputIterator>
deque(InputIterator first, InputIterator last, const Allocator& = Allocator());

Effects: Constructs a deque equal to the range [first, last), using the specified allocator.
Complexity: Linear in distance(first, last).

22.3.8.3 Capacity [deque.capacity]

void resize(size_type sz);

Preconditions: T is Cpp17MoveInsertable and Cpp17DefaultInsertable into *this.
Effects: If \( \text{sz} < \text{size()} \), erases the last \( \text{size()} - \text{sz} \) elements from the sequence. Otherwise, appends \( \text{sz} - \text{size()} \) default-inserted elements to the sequence.

```cpp
void resize(size_type sz, const T& c);
```

Preconditions: \( T \) is `std::copy_insertable` into `*this`.

Effects: If \( \text{sz} < \text{size()} \), erases the last \( \text{size()} - \text{sz} \) elements from the sequence. Otherwise, appends \( \text{sz} - \text{size()} \) copies of \( c \) to the sequence.

```cpp
void shrink_to_fit();
```

Preconditions: \( T \) is `std::move_insertable` into `*this`.

Effects: `shrink_to_fit()` is a non-binding request to reduce memory use but does not change the size of the sequence. [Note: The request is non-binding to allow latitude for implementation-specific optimizations. — end note] If the size is equal to the old capacity, or if an exception is thrown other than by the move constructor of a non-`std::copy_insertable T`, then there are no effects.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: If the size is not equal to the old capacity, then invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

### 22.3.8.4 Modifiers

**iterator insert(const_iterator position, const T& x);**

**iterator insert(const_iterator position, T&& x);**

**iterator insert(const_iterator position, size_type n, const T& x);**

**template<class InputIterator> iterator insert(const_iterator position, InputIterator first, InputIterator last);**

**iterator insert(const_iterator position, initializer_list<T>);**

**template<class... Args> reference emplace_front(Args&&... args);**

**template<class... Args> reference emplace_back(Args&&... args);**

**template<class... Args> iterator emplace(const_iterator position, Args&&... args);**

**void push_front(const T& x);**

**void push_front(T&& x);**

**void push_back(const T& x);**

**void push_back(T&& x);**

**iterator erase(const_iterator position);**

**iterator erase(const_iterator first, const_iterator last);**

**void pop_front();**

**void pop_back();**

Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element at either the beginning or end of a deque always takes constant time and causes a single call to a constructor of \( T \).

Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of \( T \) there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-`std::copy_insertable T`, the effects are unspecified.

Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque. [Note: `pop_front` and `pop_back` are erase operations. — end note]

Throws: Nothing unless an exception is thrown by the assignment operator of \( T \).
Complexity: The number of calls to the destructor of $T$ is the same as the number of elements erased, but the number of calls to the assignment operator of $T$ is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

22.3.8.5 Erasure

```cpp
template<class T, class Allocator, class U>
typename deque<T, Allocator>::size_type
erase(deque<T, Allocator>& c, const U& value);  
Effects: Equivalent to:
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

```cpp
template<class T, class Allocator, class Predicate>
type deq<T, Allocator>::size_type
erase_if(deque<T, Allocator>& c, Predicate pred);
Effects: Equivalent to:
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

22.3.9 Class template forward_list

22.3.9.1 Overview

A `forward_list` is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported. [Note: It is intended that `forward_list` have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. — end note]

A `forward_list` meets all of the requirements of a container (Table 73), except that the `size()` member function is not provided and `operator==` has linear complexity. A `forward_list` also meets all of the requirements for an allocator-aware container (Table 76). In addition, a `forward_list` provides the `assign` member functions (Table 77) and several of the optional container requirements (Table 78). Descriptions are provided here only for operations on `forward_list` that are not described in that table or for operations where there is additional semantic information.

[Note: Modifying any list requires access to the element preceding the first element of interest, but in a `forward_list` there is no constant-time way to access a preceding element. For this reason, ranges that are modified, such as those supplied to `erase` and `splice`, must be open at the beginning. — end note]

```cpp
namespace std {
  template<class T, class Allocator = allocator<T>>
  class forward_list {
    public:
      // types
      using value_type = T;
      using allocator_type = Allocator;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;
      using reference = value_type&;
      using const_reference = const value_type&;
      using size_type = implementation-defined; // see 22.2
      using difference_type = implementation-defined; // see 22.2
      using iterator = implementation-defined; // see 22.2
      using const_iterator = implementation-defined; // see 22.2

      // 22.3.9.2, construct/copy/destroy
      forward_list() : forward_list(Allocator()) {}  
      explicit forward_list(const Allocator&);  
      explicit forward_list(size_type n, const Allocator& = Allocator());
      forward_list(size_type n, const T& value, const Allocator& = Allocator());
```
template<class InputIterator>
    forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());
forward_list(const forward_list& x);
forward_list(forward_list&& x);
forward_list(const forward_list& x, const Allocator&);
forward_list(forward_list&& x, const Allocator&);
forward_list(initializer_list<T>, const Allocator& = Allocator());
    ~forward_list();
forward_list& operator=(const forward_list& x);
forward_list& operator=(forward_list&& x)
    noexcept(allocation_traits<Allocator>::is_always_equal::value);
forward_list& operator=(initializer_list<T>);

    template<class InputIterator>
    void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

    // 22.3.9.3, iterators
    iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cbefore_begin() const noexcept;
const_iterator cend() const noexcept;

    // capacity
    [[nodiscard]] bool empty() const noexcept;
size_type max_size() const noexcept;

    // 22.3.9.4, element access
    reference front();
const_reference front() const;

    // 22.3.9.5, modifiers
    template<class... Args> reference emplace_front(Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void pop_front();

    template<class... Args> iterator emplace_after(const_iterator position, Args&&... args);
iterator insert_after(const_iterator position, const T& x);
iterator insert_after(const_iterator position, T&& x);
iterator insert_after(const_iterator position, size_type n, const T& x);

    iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
iterator insert_after(const_iterator position, initializer_list<T> il);

    iterator erase_after(const_iterator position);
iterator erase_after(const_iterator position, const_iterator last);
void swap(forward_list&)
    noexcept(allocation_traits<Allocator>::is_always_equal::value);
void resize(size_type sz);
void resize(size_type sz, const value_type& c);
void clear() noexcept;

    // 22.3.9.6, forward_list operations
void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);
void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);
void splice_after(const_iterator position, forward_list& x, const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x, const_iterator first, const_iterator last);
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);
void merge(forward_list& x);
void merge(forward_list&& x);
template<class Compare> void merge(forward_list& x, Compare comp);
template<class Compare> void merge(forward_list&& x, Compare comp);
void sort();
template<class Compare> void sort(Compare comp);
void reverse() noexcept;
};

// swap
template<class T, class Allocator>
void swap(forward_list<T, Allocator>& x, forward_list<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

An incomplete type T may be used when instantiating forward_list if the allocator meets the allocator completeness requirements (16.5.3.5.1). T shall be complete before any member of the resulting specialization of forward_list is referenced.

22.3.9.2 Constructors, copy, and assignment

explicit forward_list(const Allocator&);

Effects: Constructs an empty forward_list object using the specified allocator.
Complexity: Constant.

explicit forward_list(size_type n, const Allocator& = Allocator());

Preconditions: T is Cpp17DefaultInsertable into *this.
Effects: Constructs a forward_list object with n default-inserted elements using the specified allocator.
Complexity: Linear in n.

forward_list(size_type n, const T& value, const Allocator& = Allocator());

Preconditions: T is Cpp17CopyInsertable into *this.
Effects: Constructs a forward_list object with n copies of value using the specified allocator.
Complexity: Linear in n.

template<class InputIterator>
forward_list(InputIterator, InputIterator, Allocator = Allocator());

Effects: Constructs a forward_list object equal to the range [first, last).
Complexity: Linear in distance(first, last).
22.3.9.3 Iterators

iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
const_iterator cbefore_begin() const noexcept;

1 Effects: cbefore_begin() is equivalent to const_cast<forward_list const&>(*this).before_begin().
2 Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by begin().
3 Remarks: before_begin() == end() shall equal false.

22.3.9.4 Element access

reference front();
const_reference front() const;

1 Returns: *begin()

22.3.9.5 Modifiers

None of the overloads of insert_after shall affect the validity of iterators and references, and erase_after shall invalidate only iterators and references to the erased elements. If an exception is thrown during insert_after there shall be no effect. Inserting n elements into a forward_list is linear in n, and the number of calls to the copy or move constructor of T is exactly equal to n. Erasing n elements from a forward_list is linear in n and the number of calls to the destructor of type T is exactly equal to n.

template<class... Args> reference emplace_front(Args&&... args);

1 Effects: Inserts an object of type value_type constructed with value_type(std::forward<Args>(args)...) at the beginning of the list.
2 Effects: Inserts a copy of x at the beginning of the list.
3 Effects: As if by erase_after(before_begin()).
4 Returns: An iterator pointing to the copy of x.
5 Preconditions: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
6 Effects: Inserts a copy of x after position.
7 Returns: An iterator pointing to the last inserted copy of x or position if n == 0.
8 Preconditions: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
9 Effects: Inserts n copies of x after position.
10 Returns: An iterator pointing to the last inserted copy of x or position if n == 0.
11 Preconditions: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). Neither first nor last are iterators in *this.
12 Effects: Inserts copies of elements in [first, last) after position.
13 Returns: An iterator pointing to the last inserted element or position if first == last.
14 Effects: insert_after(p, il.begin(), il.end()).
15 Returns: An iterator pointing to the last inserted element or position if il is empty.
template<class... Args>
    iterator emplace_after(const_iterator position, Args&&... args);

16 Preconditions: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
17 Effects: Inserts an object of type value_type constructed with value_type(std::forward<Args>(args)...) after position.
18 Returns: An iterator pointing to the new object.

iterator erase_after(const_iterator position);
19 Preconditions: The iterator following position is dereferenceable.
20 Effects: Erases the element pointed to by the iterator following position.
21 Returns: An iterator pointing to the element following the one that was erased, or end() if no such element exists.
22 Throws: Nothing.

iterator erase_after(const_iterator position, const_iterator last);
23 Preconditions: All iterators in the range (position, last) are dereferenceable.
24 Effects: Erases the elements in the range (position, last).
25 Returns: last.
26 Throws: Nothing.
27 void resize(size_type sz);
28 Preconditions: T is Cpp17DefaultInsertable into *this.
29 Effects: If sz < distance(begin(), end()), erases the last distance(begin(), end()) - sz elements from the list. Otherwise, inserts sz - distance(begin(), end()) default-inserted elements at the end of the list.
30 void resize(size_type sz, const value_type& c);
31 Preconditions: T is Cpp17CopyInsertable into *this.
32 Effects: If sz < distance(begin(), end()), erases the last distance(begin(), end()) - sz elements from the list. Otherwise, inserts sz - distance(begin(), end()) copies of c at the end of the list.
33 void clear() noexcept;
34 Effects: Erases all elements in the range [begin(), end()).
35 Remarks: Does not invalidate past-the-end iterators.

22.3.9.6 Operations [forwardlist.ops]
1 In this subclause, arguments for a template parameter named Predicate or BinaryPredicate shall meet the corresponding requirements in 25.2. For merge and sort, the definitions and requirements in 25.8 apply.

void splice_after(const_iterator position, forward_list& x);
2 void splice_after(const_iterator position, forward_list&& x);
3 Preconditions: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
4 get_allocator() == x.get_allocator() is true. addressof(x) != this is true.
5 Effects: Inserts the contents of x after position, and x becomes empty. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.
6 Throws: Nothing.
7 Complexity: \(O(\text{distance}(x.\text{begin}(), x.\text{end}()))\)
8
void splice_after(const_iterator position, forward_list& x, const_iterator i);
9 void splice_after(const_iterator position, forward_list&& x, const_iterator i);
10 Preconditions: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
11 The iterator following i is a dereferenceable iterator in x. get_allocator() == x.get_allocator() is true.
Effects: Inserts the element following i into *this, following position, and removes it from x. The result is unchanged if position == i or position == ++i. Pointers and references to *++i continue to refer to the same element but as a member of *this. Iterators to *++i continue to refer to the same element, but now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: \(O(1)\)

```cpp
void splice_after(const_iterator position, forward_list& x, const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x, const_iterator first, const_iterator last);
```

Preconditions: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). (first, last) is a valid range in x, and all iterators in the range (first, last) are dereferenceable. position is not an iterator in the range (first, last). get_allocator() == x.get_allocator() is true.

Effects: Inserts elements in the range (first, last) after position and removes the elements from x. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Complexity: \(O(distance(first, last))\)

```cpp
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
```

Effects: Erases all the elements in the list referred to by a list iterator i for which the following conditions hold: *i == value (for remove()), pred(*i) is true (for remove_if()). Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

Complexity: Exactly distance(begin(), end()) applications of the corresponding predicate.

Remarks: Stable (16.5.5.8).

```cpp
size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate pred);
```

Effects: Erases all but the first element from every consecutive group of equal elements referred to by the iterator i in the range [first + 1, last) for which *i == *(i-1) (for the version with no arguments) or pred(*i, *(i - 1)) (for the version with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

Complexity: If the range [first, last) is not empty, exactly (last - first) - 1 applications of the corresponding predicate, otherwise no applications of the predicate.

```cpp
void merge(forward_list& x);
void merge(forward_list&& x);
template<class Compare> void merge(forward_list& x, Compare comp);
template<class Compare> void merge(forward_list&& x, Compare comp);
```

Preconditions: *this and x are both sorted with respect to the comparator operator< (for the first two overloads), or comp (for the last two overloads), and get_allocator() == x.get_allocator() is true.

Effects: Merges the two sorted ranges [begin(), end()) and [x.begin(), x.end()). x is empty after the merge. If an exception is thrown other than by a comparison there are no effects. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Complexity: At most distance(begin(), end()) + distance(x.begin(), x.end()) - 1 comparisons.

§ 22.3.9.6
void sort();
template<class Compare> void sort(Compare comp);

Effects: Sorts the list according to the operator< or the comp function object. If an exception is thrown, the order of the elements in *this is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately $N \log N$ comparisons, where $N$ is distance(begin(), end()).

Remarks: Stable (16.5.5.8).

void reverse() noexcept;

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

22.3.9.7 Erasure

template<class T, class Allocator, class U>
typename forward_list<T, Allocator>::size_type
erase(forward_list<T, Allocator>& c, const U& value);

Effects: Equivalent to:
return erase_if(c, [&](auto& elem) { return elem == value; });

template<class T, class Allocator, class Predicate>
typename forward_list<T, Allocator>::size_type
erase_if(forward_list<T, Allocator>& c, Predicate pred);

Effects: Equivalent to:
return c.remove_if(pred);

22.3.10 Class template list

22.3.10.1 Overview

A list is a sequence container that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (22.3.11) and deques (22.3.8), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

A list meets all of the requirements of a container, of a reversible container (given in two tables in 22.2), of a sequence container, including most of the optional sequence container requirements (22.2.3), and of an allocator-aware container (Table 76). The exceptions are the operator[] and at member functions, which are not provided. Descriptions are provided here only for operations on list that are not described in one of these tables or for operations where there is additional semantic information.

namespace std {
    template<class T, class Allocator = allocator<T>>
    class list {
    public:
        // types
        using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 22.2
        using difference_type = implementation-defined; // see 22.2
        using iterator = implementation-defined; // see 22.2
        using const_iterator = implementation-defined; // see 22.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 22.3.10.2, construct/copy/destroy
        list() : list(Allocator()) { }
        explicit list(const Allocator&);

        list(const list& another); // copy constructor
        list& operator=(const list& another); // assignment operator
        list& operator=(const Allocator&); // assignment operator

        list(Deque&& other) noexcept; // move constructor
        list& operator=(Deque&& other); // move assignment operator
        list& operator=(const Allocator&); // move assignment operator

        void push_back(const T& elem);
        void push_back(T&& elem);
        void push_front(const T& elem);
        void push_front(T&& elem);

template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();
template<class BinaryPredicate>
size_type unique(BinaryPredicate binary_pred);

void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);

void sort();
void reverse() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter_value_type<InputIterator>>> list(InputIterator, InputIterator, Allocator = Allocator())
  -> list<iter_value_type<InputIterator>, Allocator>;

// swap
template<class T, class Allocator>
void swap(list<T, Allocator>& x, list<T, Allocator>& y)
  noexcept(x.swap(y));
}

3 An incomplete type T may be used when instantiating list if the allocator meets the allocator completeness requirements (16.5.3.5.1). T shall be complete before any member of the resulting specialization of list is referenced.

22.3.10.2 Constructors, copy, and assignment

explicit list(const Allocator&);
  Effects: Constructs an empty list, using the specified allocator.
  Complexity: Constant.

explicit list(size_type n, const Allocator& = Allocator());
  Preconditions: T is Cpp17DefaultInsertable into *this.
  Effects: Constructs a list with n default-inserted elements using the specified allocator.
  Complexity: Linear in n.

list(size_type n, const T& value, const Allocator& = Allocator());
  Preconditions: T is Cpp17CopyInsertable into *this.
  Effects: Constructs a list with n copies of value, using the specified allocator.
  Complexity: Linear in n.

§ 22.3.10.2 815
template<class InputIterator>
list(InputIterator first, InputIterator last, const Allocator& = Allocator());

Effects: Constructs a list equal to the range \([first, last)\).

Complexity: Linear in distance\((first, last)\).

22.3.10.3 Capacity

void resize(size_type sz);

Preconditions: \(T\) is Cpp17DefaultInsertable into \(*this\).

Effects: If \(\text{size()} < sz\), appends \(sz - \text{size()}\) default-inserted elements to the sequence. If \(sz \leq \text{size()}\), equivalent to:

\[
\text{list}<T>::\text{iterator} \text{ it} = \text{begin}();
\text{advance(it, sz);} \text{;}
\text{erase(it, end());}
\]

void resize(size_type sz, const T& c);

Preconditions: \(T\) is Cpp17CopyInsertable into \(*this\).

Effects: As if by:

\[
\text{if} (sz > \text{size()} \text{;}
\text{insert(end(), sz-size(), c);} \text{;}
\text{else if} (sz < \text{size()} \text{)} \{
\text{iterator i} = \text{begin}();
\text{advance(i, sz);} \text{;}
\text{erase(i, end());}
\text{else}
\text{;}
\text{// do nothing}
\]

22.3.10.4 Modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first,
InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

Complexity: Insertion of a single element into a list takes constant time and exactly one call to a constructor of \(T\). Insertion of multiple elements into a list is linear in the number of elements inserted, and the number of calls to the copy constructor or move constructor of \(T\) is exactly equal to the number of elements inserted.

Remarks: Does not affect the validity of iterators and references. If an exception is thrown there are no effects.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);

void pop_front();
void pop_back();
void clear() noexcept;

Effects: Invalidates only the iterators and references to the erased elements.

Throws: Nothing.
Complexity: Erasing a single element is a constant time operation with a single call to the destructor of T. Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type T is exactly equal to the size of the range.

22.3.10.5 Operations [list.ops]

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them. In this subclause, arguments for a template parameter named Predicate or BinaryPredicate shall meet the corresponding requirements in 25.2. For merge and sort, the definitions and requirements in 25.8 apply.

list provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undefined if get_allocator() != x.get_allocator().

```cpp
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
```

Preconditions: x != this is true.

Effects: Inserts the contents of x before position and x becomes empty. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time.

```cpp
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
```

Preconditions: i is a valid dereferenceable iterator of x.

Effects: Inserts an element pointed to by i from list x before position and removes the element from x. The result is unchanged if position == i or position == ++i. Pointers and references to *i continue to refer to this same element but as a member of *this. Iterators to *i (including i itself) continue to refer to the same element, but now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time.

```cpp
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);
```

Preconditions: [first, last) is a valid range in x. position is not an iterator in the range [first, last).

Effects: Inserts elements in the range [first, last) before position and removes the elements from x. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time if addressof(x) == this; otherwise, linear time.

```cpp
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
```

Effects: Erases all the elements in the list referred to by a list iterator i for which the following conditions hold: *i == value, pred(*i) != false. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by *i == value or pred(*i) != false.

Complexity: Exactly size() applications of the corresponding predicate.

Remarks: Stable (16.5.5.8).

---

226) As specified in 16.5.3.5, the requirements in this Clause apply only to lists whose allocators compare equal.
size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);

Effects: Erases all but the first element from every consecutive group of equal elements referred to by the iterator \( i \) in the range \([\text{first} + 1, \text{last})\) for which \( *i == *(i-1) \) (for the version of unique with no arguments) or \( \text{pred}(i, *(i - 1)) \) (for the version of unique with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by \( *i == *(i-1) \) or \( \text{pred}(i, *(i - 1)) \).

Complexity: If the range \([\text{first}, \text{last})\) is not empty, exactly \((\text{last} - \text{first}) - 1\) applications of the corresponding predicate, otherwise no applications of the predicate.

void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);

Preconditions: Both the list and the argument list shall be sorted with respect to the comparator operator\(<\) (for the first two overloads) or \(\text{comp}\) (for the last two overloads), and get_allocator() == x.get_allocator() is true.

Effects: If addressof(x) == this, does nothing; otherwise, merges the two sorted ranges \([\text{begin}, \text{end})\) and \([x.\text{begin}, x.\text{end})\). The result is a range in which the elements will be sorted in non-decreasing order according to the ordering defined by \(\text{comp}\); that is, for every iterator \( i \), in the range other than the first, the condition \( \text{comp}(i, *(i - 1)) \) will be false. Pointers and references to the moved elements of \( x \) now refer to those same elements but as members of \*this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \*this, not into \( x \).

Complexity: At most \( \text{size}() + x.\text{size}() - 1 \) applications of \(\text{comp}\) if addressof(x) != this; otherwise, no applications of \(\text{comp}\) are performed. If an exception is thrown other than by a comparison there are no effects.

Remarks: Stable (16.5.5.8). If addressof(x) != this, the range \([x.\text{begin}, x.\text{end})\) is empty after the merge. No elements are copied by this operation.

void reverse() noexcept;

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

void sort();
template<class Compare> void sort(Compare comp);

Effects: Sorts the list according to the operator\(<\) or a \(\text{Compare}\) function object. If an exception is thrown, the order of the elements in \*this is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately \( N \log N \) comparisons, where \( N == \text{size}() \).

Remarks: Stable (16.5.5.8).

### 22.3.10.6 Erasure

template<class T, class Allocator, class U>
typename list<T, Allocator>::size_type
erase(list<T, Allocator>& c, const U& value);

Effects: Equivalent to: \( \text{return erase\_if}(c, [&](auto& elem) \{ return elem == value; \}); \)

template<class T, class Allocator, class Predicate>
typename list<T, Allocator>::size_type
erase\_if(list<T, Allocator>& c, Predicate pred);

Effects: Equivalent to: \( \text{return c.remove\_if}(pred) \);
A vector is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

A vector meets all of the requirements of a container and of a reversible container (given in two tables in 22.2), of a sequence container, including most of the optional sequence container requirements (22.2.3), of an allocator-aware container (Table 76), and, for an element type other than bool, of a contiguous container (22.2.1). The exceptions are the push_front, pop_front, and emplace_front member functions, which are not provided. Descriptions are provided here only for operations on vector that are not described in one of these tables or for operations where there is additional semantic information.

The types iterator and const_iterator meet the constexpr iterator requirements (23.3.1).

```cpp
namespace std {
    template<class T, class Allocator = allocator<T>>
    class vector {
    public:
        // types
        using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;

[[nodiscard]] constexpr bool empty() const noexcept;
constexpr size_type size() const noexcept;
constexpr size_type max_size() const noexcept;
constexpr size_type capacity() const noexcept;
constexpr void resize(size_type sz);
constexpr void resize(size_type sz, const T& c);
constexpr void reserve(size_type n);
constexpr void shrink_to_fit();

// element access
constexpr reference operator[](size_type n);
constexpr const_reference operator[](size_type n) const;
constexpr const_reference at(size_type n) const;
constexpr reference at(size_type n);
constexpr reference front();
constexpr const_reference front() const;
constexpr reference back();
constexpr const_reference back() const;

// 22.3.11.4, data access
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

// 22.3.11.5, modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
constexpr void pop_back();

template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
constexpr iterator insert(const_iterator position, InputIterator first, InputIterator last);
constexpr iterator insert(const_iterator position, initializer_list<T> il);
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
vector<InputIterator, InputIterator, Allocator = Allocator>()
-> vector<iter-value-type<InputIterator>, Allocator>;

// swap
template<class T, class Allocator>
constexpr void swap(vector<T, Allocator>& x, vector<T, Allocator>& y)
  noexcept(noexcept(x.swap(y)));
}
An incomplete type \( T \) may be used when instantiating \( \text{vector} \) if the allocator meets the allocator completeness requirements (16.5.3.5.1). \( T \) shall be complete before any member of the resulting specialization of \( \text{vector} \) is referenced.

### 22.3.11.2 Constructors, copy, and assignment

```cpp
constexpr explicit \text{vector}(\text{const Allocator}&) noexcept;
    \text{Effects}: Constructs an empty \text{vector}, using the specified allocator.
    \text{Complexity}: Constant.
```

```cpp
constexpr explicit \text{vector}(\text{size_type} n, \text{const Allocator}&) = \text{Allocator}());
    \text{Preconditions}: \( T \) is Cpp17DefaultInsertable into *this.
    \text{Effects}: Constructs a \text{vector} with \( n \) default-inserted elements using the specified allocator.
    \text{Complexity}: Linear in \( n \).
```

```cpp
\text{constexpr \text{vector}(\text{size_type} n, \text{const T} & value, \text{const Allocator}&) = \text{Allocator}());
    \text{Preconditions}: \( T \) is Cpp17CopyInsertable into *this.
    \text{Effects}: Constructs a \text{vector} with \( n \) copies of \text{value}, using the specified allocator.
    \text{Complexity}: Linear in \( n \).
```

```cpp
\text{template<\text{class InputIterator}>}
\text{constexpr \text{vector}(\text{InputIterator first, InputIterator last, \text{const Allocator}&) = \text{Allocator}());}
    \text{Effects}: Constructs a \text{vector} equal to the range \([\text{first, last})\), using the specified allocator.
    \text{Complexity}: Makes only \( N \) calls to the copy constructor of \( T \) (where \( N \) is the distance between \text{first} and \text{last}) and no reallocations if iterators \text{first} and \text{last} are of forward, bidirectional, or random access categories. It makes order \( N \) calls to the copy constructor of \( T \) and order \( \log N \) reallocations if they are just input iterators.
```

### 22.3.11.3 Capacity

```cpp
\text{constexpr \text{size_type capacity}() const noexcept;}
    \text{Returns}: The total number of elements that the \text{vector} can hold without requiring reallocation.
    \text{Complexity}: Constant time.
```

```cpp
\text{constexpr void reserve(size_type n);} 
    \text{Preconditions}: \( T \) is Cpp17MoveInsertable into *this.
    \text{Effects}: A directive that informs a \text{vector} of a planned change in size, so that it can manage the storage allocation accordingly. After \text{reserve}(), \text{capacity}() is greater or equal to the argument of \text{reserve}() if reallocation happens; and equal to the previous value of \text{capacity}() otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of \text{reserve}(). If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable type, there are no effects.
    \text{Throws}: \text{length_error} if \( n > \text{max_size()} \).
    \text{Complexity}: It does not change the size of the sequence and takes at most linear time in the size of the sequence.
    \text{Remarks}: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. \text{[Note}: If no reallocation happens, they remain valid. \text{— end note]} No reallocation shall take place during insertions that happen after a call to \text{reserve}() until an insertion would make the size of the \text{vector} greater than the value of \text{capacity}().
```

```cpp
\text{constexpr void shrink_to_fit();}
    \text{Preconditions}: \( T \) is Cpp17MoveInsertable into *this.
    \text{Effects}: \text{shrink_to_fit} is a non-binding request to reduce \text{capacity}() to \text{size}(). \text{[Note}: The request is non-binding to allow latitude for implementation-specific optimizations. \text{— end note]} It does not increase
```

---

227) \text{reserve}() uses \text{Allocator::allocate()} which may throw an appropriate exception.
capacity(), but may reduce capacity() by causing reallocation. If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T there are no effects.

**Complexity:** If reallocation happens, linear in the size of the sequence.

**Remarks:** Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator. [*Note: If no reallocation happens, they remain valid. — end note*]

```cpp
constexpr void swap(vector&amp; x)
    noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
             allocator_traits<Allocator>::is_always_equal::value);
```

**Effects:** Exchanges the contents and capacity() of *this with that of x.

**Complexity:** Constant time.

```cpp
constexpr void resize(size_type sz);
```

**Preconditions:** T is Cpp17MoveInsertable and Cpp17DefaultInsertable into *this.

**Effects:** If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() default-inserted elements to the sequence.

**Remarks:** If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T there are no effects.

```cpp
constexpr void resize(size_type sz, const T&amp; c);
```

**Preconditions:** T is Cpp17CopyInsertable into *this.

**Effects:** If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() copies of c to the sequence.

**Remarks:** If an exception is thrown there are no effects.

### 22.3.11.4 Data

```cpp
constexpr T* data() noexcept;
```

**Returns:** A pointer such that [data(), data() + size()) is a valid range. For a non-empty vector, data() == addressof(front()).

**Complexity:** Constant time.

### 22.3.11.5 Modifiers

```cpp
constexpr iterator insert(const_iterator position, const T&amp; x);
```

**Complexity:** If reallocation happens, linear in the number of elements of the resulting vector; otherwise, linear in the number of elements inserted plus the distance to the end of the vector.

**Remarks:** Causes reallocation if the new size is greater than the old capacity. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. If no reallocation happens, then references, pointers, and iterators before the insertion point remain valid but those at or after the insertion point, including the past-the-end iterator, are invalidated. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T or by any InputIterator operation there are no effects. If an exception is thrown while inserting a single element at the end and T is Cpp17CopyInsertable or is_nothrow_move_constructible_v&lt;T&gt; is true, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-Cpp17CopyInsertable T, the effects are unspecified.

§ 22.3.11.5 822
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void pop_back();

Effects: Invalidates iterators and references at or after the point of the erase.

Throws: Nothing unless an exception is thrown by the assignment operator or move assignment operator of T.

Complexity: The destructor of T is called the number of times equal to the number of the elements erased, but the assignment operator of T is called the number of times equal to the number of elements in the vector after the erased elements.

22.3.11.6 Erasure

template<class T, class Allocator, class U>
constexpr typename vector<T, Allocator>::size_type
erase(vector<T, Allocator>& c, const U& value);

Effects: Equivalent to:
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

template<class T, class Allocator, class Predicate>
constexpr typename vector<T, Allocator>::size_type
erase_if(vector<T, Allocator>& c, Predicate pred);

Effects: Equivalent to:
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

22.3.12 Class vector<bool>

To optimize space allocation, a specialization of vector for bool elements is provided:

namespace std {
    template<class Allocator>
    class vector<bool, Allocator> {
    public:
        // types
        using value_type = bool;
        using allocator_type = Allocator;
        using pointer = implementation-defined;
        using const_pointer = implementation-defined;
        using const_reference = bool;
        using size_type = implementation-defined; // see 22.2
        using difference_type = implementation-defined; // see 22.2
        using iterator = implementation-defined; // see 22.2
        using const_iterator = implementation-defined; // see 22.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;
        // bit reference
        class reference {
            friend class vector;
            constexpr reference() noexcept;
            public:
                constexpr reference(const reference&) = default;
                constexpr ~reference();
                constexpr operator bool() const noexcept;
                constexpr operator= (const bool x) noexcept;
                constexpr operator=(const reference& x) noexcept;
                constexpr operator=(const reference& x) noexcept;
                constexpr void flip() noexcept;  // flips the bit
            };

§ 22.3.12
// construct/copy/destroy
constexpr vector() : vector(Allocator()) { }
constexpr explicit vector(const Allocator&);
constexpr explicit vector(size_type n, const Allocator& = Allocator());
constexpr vector(size_type n, const bool& value, const Allocator& = Allocator());
template<class InputIterator>
constexpr vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
constexpr vector(const vector& x);
constexpr vector(vector&& x);
constexpr vector(const vector&, const Allocator& = Allocator());
constexpr vector(vector&&, const Allocator&);
constexpr vector(initializer_list<bool>, const Allocator& = Allocator());
constexpr ~vector();
constexpr vector& operator=(const vector& x);
constexpr vector& operator=(vector&& x);
constexpr vector& operator=(initializer_list<bool>);

// iterators
constexpr iterator begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;
constexpr reverse_iterator rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr reverse_iterator rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_iterator cbegin() const noexcept;
constexpr const_iterator cend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

// capacity
[[nodiscard]] constexpr bool empty() const noexcept;
constexpr size_type size() const noexcept;
constexpr size_type max_size() const noexcept;
constexpr size_type capacity() const noexcept;
constexpr void resize(size_type sz, bool c = false);
constexpr void reserve(size_type n);
constexpr void shrink_to_fit();

// element access
constexpr reference operator[](size_type n);
constexpr const_reference operator[](size_type n) const;
constexpr const_reference at(size_type n) const;
constexpr reference at(size_type n);
constexpr reference front();
constexpr const_reference front() const;
constexpr reference back();
constexpr const_reference back() const;

// modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
constexpr void push_back(const bool& x);
constexpr void pop_back();
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const bool& x);
constexpr iterator insert(const_iterator position, size_type n, const bool& x);
template<class InputIterator>  
constexpr iterator insert(const_iterator position,  
                        InputIterator first, InputIterator last);  
constexpr iterator insert(const_iterator position, initializer_list<bool> il);  
constexpr iterator erase(const_iterator position);  
constexpr iterator erase(const_iterator first, const_iterator last);  
constexpr void swap(vector&);  
constexpr static void swap(reference x, reference y) noexcept;  
constexpr void flip() noexcept;  // flips all bits  
constexpr void clear() noexcept;  
};

 Unless described below, all operations have the same requirements and semantics as the primary vector template, except that operations dealing with the bool value type map to bit values in the container storage and allocator_traits::construct (20.10.9.2) is not used to construct these values.

 There is no requirement that the data be stored as a contiguous allocation of bool values. A space-optimized representation of bits is recommended instead.

 reference is a class that simulates the behavior of references of a single bit in vector<bool>. The conversion function returns true when the bit is set, and false otherwise. The assignment operator sets the bit when the argument is (convertible to) true and clears it otherwise. flip reverses the state of the bit.

 constexpr void flip() noexcept;  

 Effects: Replaces each element in the container with its complement.

 constexpr static void swap(reference x, reference y) noexcept;  

 Effects: Exchanges the contents of x and y as if by:

 bool b = x;
 x = y;
 y = b;

 template<class Allocator> struct hash<vector<bool, Allocator>>;

 The specialization is enabled (20.14.18).

 22.4 Associative containers [associative]

 22.4.1 In general [associative.general]

 The header <map> defines the class templates map and multimap; the header <set> defines the class templates set and multiset.

 The following exposition-only alias templates may appear in deduction guides for associative containers:

 template<class InputIterator>  
 using iter-value-type =  
 typename iterator_traits<InputIterator>::value_type;  // exposition only  
 template<class InputIterator>  
 using iter-key-type = remove_const_t<  
 typename iterator_traits<InputIterator>::value_type::first_type>;  // exposition only  
 template<class InputIterator>  
 using iter-mapped-type =  
 typename iterator_traits<InputIterator>::value_type::second_type;  // exposition only  
 template<class InputIterator>  
 using iter-to-alloc-type = pair<  
 add_const_t<typename iterator_traits<InputIterator>::value_type::first_type>,  
 typename iterator_traits<InputIterator>::value_type::second_type>;  // exposition only  

 22.4.2 Header <map> synopsis [associative.map.syn]

 #include <compare>  // see 17.11.1  
 #include <initializer_list>  // see 17.10.1
namespace std {

// 22.4.4, class template map
class map {
  template<class Key, class T, class Compare = less<Key>,
           class Allocator = allocator<pair<const Key, T>>>
  class map;

  template<class Key, class T, class Compare, class Allocator>
  bool operator==(const map<Key, T, Compare, Allocator>& x,
                  const map<Key, T, Compare, Allocator>& y);

  template<class Key, class T, class Compare, class Allocator>
  synth-three-way-result<pair<const Key, T>>
  operator<=>(const map<Key, T, Compare, Allocator>& x,
               const map<Key, T, Compare, Allocator>& y);

    using set = std::set<Key, Compare, polymorphic_allocator<Key>>;

  template<class Key, class Compare = less<Key>>
    using multiset = std::multiset<Key, Compare, polymorphic_allocator<Key>>;
}

22.4.4 Class template map

22.4.4.1 Overview

1 A map is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional iterators.

2 A map meets all of the requirements of a container, of a reversible container (22.2), of an associative container (22.2.6), and of an allocator-aware container (Table 76). A map also provides most operations described in 22.2.6 for unique keys. This means that a map supports the a_uniq operations in 22.2.6 but not the a_eq operations. For a map<Key, T> the key_type is Key and the value_type is pair<const Key, T>. Descriptions are provided here only for operations on map that are not described in one of those tables or for operations where there is additional semantic information.

namespace std {
  template<class Key, class T, class Compare = less<Key>,
           class Allocator = allocator<pair<const Key, T>>>
    class map {
      public:
        // types
        using key_type = Key;
        using mapped_type = T;

§ 22.4.4.1
using value_type = pair<const Key, T>;
using key_compare = Compare;
using allocator_type = Allocator;
using pointer = typename allocator_traits<Allocator>::pointer;
using const_pointer = typename allocator_traits<Allocator>::const_pointer;
using reference = value_type&;
using const_reference = const value_type&;
using size_type = implementation-defined; // see 22.2
using difference_type = implementation-defined; // see 22.2
using iterator = implementation-defined; // see 22.2
using const_iterator = implementation-defined; // see 22.2
using reverse_iterator = std::reverse_iterator<iterator>;
using const_reverse_iterator = std::reverse_iterator<const_iterator>;

§ 22.4.4.1
22.4.4.2 Constructors, copy, and assignment

explicit map(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty map using the specified comparison object and allocator.

Complexity: Constant.

template<class InputIterator>
map(InputIterator first, InputIterator last,
const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in \(N\) if the range [first, last) is already sorted using \(comp\) and otherwise \(N \log N\), where \(N\) is last - first.

22.4.4.3 Element access

mapped_type& operator[](const key_type& x);

Effects: Equivalent to: return try_emplace(x).first->second;

mapped_type& operator[](key_type&& x);

Effects: Equivalent to: return try_emplace(move(x)).first->second;

mapped_type& at(const key_type& x);
const mapped_type& at(const key_type& x) const;

Returns: A reference to the mapped_type corresponding to \(x\) in *this.

Complexity: Logarithmic.

22.4.4.4 Modifiers

template<class P>
pair<iterator, bool> insert(P&& x);

template<class P>
iterator insert(const_iterator position, P&& x);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).

template<class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to \(k\), there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \(k\).

Complexity: The same as emplace and emplace_hint, respectively.

template<class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into map from
piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args) ...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts
an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)),
forward_as_tuple(std::forward<Args>(args) ...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took
place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Preconditions: value_type is Cpp17EmplaceConstructible into map from k, forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj)
to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took
place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

22.4.5 Erasure

template<class Key, class T, class Compare, class Allocator, class Predicate>
typename map<Key, T, Compare, Allocator>::size_type
erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);

Effects: Equivalent to:

auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();

22.4.5 Class template multimap

22.4.5.1 Overview

A multimap is an associative container that supports equivalent keys (possibly containing multiple copies of the
same key value) and provides for fast retrieval of values of another type T based on the keys. The multimap class
supports bidirectional iterators.
A multimap meets all of the requirements of a container and of a reversible container (22.2), of an associative container (22.2.6), and of an allocator-aware container (Table 76). A multimap also provides most operations described in 22.2.6 for equal keys. This means that a multimap supports the a_eq operations in 22.2.6 but not the a_uniq operations. For a multimap<Key,T> the key_type is Key and the value_type is pair<const Key,T>. Descriptions are provided here only for operations on multimap that are not described in one of those tables or for operations where there is additional semantic information.

typename multimap<Key, T, Compare, Allocator>::size_type
erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);
```

**Effects:** Equivalent to:

```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

22.4.6 Class template set

22.4.6.1 Overview

A set is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of the keys themselves. The set class supports bidirectional iterators.

A set meets all of the requirements of a container, of a reversible container (22.2), of an associative container (22.2.6), and of an allocator-aware container (Table 76). A set also provides most operations described in 22.2.6 for unique keys. This means that a set supports the a_uniq operations in 22.2.6 but not the a_eq operations. For a set<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on set that are not described in one of these tables and for operations where there is additional semantic information.

```
namespace std {
  template<class Key, class Compare = less<Key>,
           class Allocator = allocator<Key>>
class set {
    public:
      // types
      using key_type = Key;
      using key_compare = Compare;
      using value_type = Key;
      using value_compare = Compare;
      using allocator_type = Allocator;
```
using pointer = typename allocator_traits<Allocator>::pointer;
using const_pointer = typename allocator_traits<Allocator>::const_pointer;
using reference = value_type&;
using const_reference = const value_type&;
using size_type = implementation-defined; // see 22.2
using difference_type = implementation-defined; // see 22.2
using iterator = implementation-defined; // see 22.2
using const_iterator = implementation-defined; // see 22.2
using reverse_iterator = std::reverse_iterator<iterator>;
using const_reverse_iterator = std::reverse_iterator<const_iterator>;
using node_type = unspecified;
using insert_return_type = insert-return-type<iterator, node_type>;

// swap 
void swap(set<Key, Compare, Allocator>& x, 
  set<Key, Compare, Allocator>& y) 
  noexcept(noexcept(x.swap(y)));

22.4.6.2 Constructors, copy, and assignment 

explicit set(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison objects and allocator.

Complexity: Constant.

template<class InputIterator>
set(InputIterator first, InputIterator last, 
  const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison object and allocator, and inserts elements 
from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, 
where N is last - first.

22.4.6.3 Erasure 

template<class Key, class Compare, class Allocator, class Predicate> 
typename set<Key, Compare, Allocator>::size_type 
erase_if(set<Key, Compare, Allocator>& c, Predicate pred);

Effects: Equivalent to:

auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();

22.4.7 Class template multiset 

22.4.7.1 Overview 

A multiset is an associative container that supports equivalent keys (possibly contains multiple copies of the same 
key value) and provides for fast retrieval of the keys themselves. The multiset class supports bidirectional iterators.
A multiset meets all of the requirements of a container, of a reversible container (22.2), of an associative container (22.2.6), and of an allocator-aware container (Table 76). multiset also provides most operations described in 22.2.6 for duplicate keys. This means that a multiset supports the a_eq operations in 22.2.6 but not the a_uniq operations. For a multiset<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on multiset that are not described in one of these tables and for operations where there is additional semantic information.

   }
}  
return original_size - c.size();

22.5 Unordered associative containers

22.5.1 In general

The header <unordered_map> defines the class templates unordered_map and unordered_multimap; the header <unordered_set> defines the class templates unordered_set and unordered_multiset.

The exposition-only alias templates iter-value-type, iter-key-type, iter-mapped-type, and iter-to-alloc-type defined in 22.4.1 may appear in deduction guides for unordered containers.

22.5.2 Header <unordered_map> synopsis

```
#include <compare>    // see 17.11.1
#include <initializer_list>    // see 17.10.1

namespace std {
    // 22.5.4, class template unordered_map
    template<
        class Key,
        class T,
        class Hash = hash<Key>,
        class Pred = equal_to<Key>,
        class Alloc = allocator<pair<const Key, T>>>
    class unordered_map;

    // 22.5.5, class template unordered_multimap
    template<
        class Key,
        class T,
        class Hash = hash<Key>,

22.5.4 Class template unordered_map

22.5.4.1 Overview

An unordered_map is an unordered associative container that supports unique keys (an unordered_map contains at most one of each key value) and that associates values of another type mapped_type with the keys. The unordered_map class supports forward iterators.

An unordered_map meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 76). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_map supports the a_uniq operations in that table, not the a_eq operations. For an unordered_map<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

Subclause 22.5.4 only describes operations on unordered_map that are not described in one of the requirement tables, or for which there is additional semantic information.
// 22.5.4.2, construct/copy/destroy

  equal_to<iter-key-type<InputIterator>>, Allocator>;
template<class InputIterator, class Allocator>
unordered_map(InputIterator, InputIterator, Allocator)
-> unordered_map<iter-key-type<InputIterator>, iter-mapped-type<InputIterator>,
  hash<iter-key-type<InputIterator>>,
  equal_to<iter-key-type<InputIterator>>, Allocator>;
A `size_type` parameter type in an `unordered_map` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

### 22.5.4.2 Constructors

```cpp
template<class InputIterator, class Hash, class Allocator>
unordered_map(InputIterator, InputIterator, typename see below::size_type, Hash, Allocator)
-> unordered_map<iter-key-type<InputIterator>, iter-mapped-type<InputIterator>, Hash, equal_to<iter-key-type<InputIterator>>, Allocator>;
```

```cpp
template<class Key, class T, class Allocator>
unordered_map(initializer_list<pair<Key, T>>, typename see below::size_type, Hash, Allocator)
-> unordered_map<Key, T, Hash, equal_to<Key>, Allocator>;
```

```cpp
template<class Key, class T, class Allocator>
unordered_map(initializer_list<pair<Key, T>>, Allocator)
-> unordered_map<Key, T, equal_to<Key>, Allocator>;
```

```cpp
template<class Key, class T, class Hash, class Allocator>
unordered_map(initializer_list<pair<Key, T>>, typename see below::size_type, Hash, Allocator)
-> unordered_map<Key, T, Hash, equal_to<Key>, Allocator>;
```

```cpp
// swap
template<class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_map<Key, T, Hash, Pred, Alloc>& x, unordered_map<Key, T, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));
}
```

**Effects:**
- Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns `1.0`.
- `Complexity:` Constant.

```cpp
template<class InputIterator>
unordered_map(InputIterator f, InputIterator l, size_type n = see below, const hasher& hf = hasher(), const key_equal& eql = key_equal(), const allocator_type& a = allocator_type());
```

```cpp
unordered_map(initializer_list<value_type> il, size_type n = see below, const hasher& hf = hasher(), const key_equal& eql = key_equal(), const allocator_type& a = allocator_type());
```

**Effects:**
- Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)` for the first form, or from the range `[il.begin(), il.end())` for the second form. `max_load_factor()` returns `1.0`.
- `Complexity:` Average case linear, worst case quadratic.

### 22.5.4.3 Element access

```cpp
mapped_type& operator[](const key_type& k);
```

**Effects:**
- Equivalent to: `return try_emplace(k).first->second;`
mapped_type& operator[](key_type&& k);

Effects: Equivalent to: return try_emplace(move(k)).first->second;

mapped_type& at(const key_type& k);
const mapped_type& at(const key_type& k) const;

Returns: A reference to x.second, where x is the (unique) element whose key is equivalent to k.

Throws: An exception object of type out_of_range if no such element is present.

22.5.4.4 Modifiers

template<class P>
pair<iterator, bool> insert(P&& obj);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: Equivalent to: return emplace(std::forward<P>(obj));

template<class P>
iterator insert(const_iterator hint, P&& obj);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

template<class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from piecewise_construct,
forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)\ldots).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise
inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k),
forward_as_tuple(std::forward<Args>(args)\ldots).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took
place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from piecewise_construct,
forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)\ldots).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts
an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)),
forward_as_tuple(std::forward<Args>(args)\ldots).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took
place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from k, std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj)
to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

§ 22.5.4.4
template<class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.
Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from std::move(k), std::forward<M>(obj).
Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

22.5.4.5 Erasure [unord.map.eration]

template<class K, class T, class H, class P, class A, class Predicate>
typename unordered_map<K, T, H, P, A>::size_type
erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);

Effects: Equivalent to:
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
} return original_size - c.size();

22.5.5 Class template unordered_multimap [unord.multimap]

22.5.5.1 Overview [unord.multimap.overview]

An unordered_multimap is an unordered associative container that supports equivalent keys (an instance of unordered_multimap may contain multiple copies of each key value) and that associates values of another type mapped_type with the keys. The unordered_multimap class supports forward iterators.

An unordered_multimap meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 76). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multimap supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multimap<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

Subclause 22.5.5 only describes operations on unordered_multimap that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
  template<class Key,
    class T,
    class Hash = hash<Key>,
    class Pred = equal_to<Key>,
    class Allocator = allocator<pair<const Key, T>>>
  class unordered_multimap {
    public:
      // types
      using key_type = Key;

noexcept(noexcept(x.swap(y)));

// A size_type parameter type in an unordered_multimap deduction guide refers to the size_type member type
// of the type deduced by the deduction guide.

22.5.5.2 Constructors

unordered_multimap() : unordered_multimap(size_type(see below)) ( }
explicit unordered_multimap(size_type n,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multimap using the specified hash function, key equality predicate,
and allocator, and using at least \( n \) buckets. If \( n \) is not provided, the number of buckets
is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_multimap(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

unordered_multimap(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multimap using the specified hash function, key equality predicate,
and allocator, and using at least \( n \) buckets. Then inserts elements from the range \([f, l)\) for the first form,
or from the range \([il.begin(), il.end())\) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

22.5.5.3 Modifiers

template<class P>
iterator insert(P&& obj);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: Equivalent to: return emplace(std::forward<P>(obj));
template<class P>
    iterator insert(const_iterator hint, P&& obj);

    Constraints: is_constructible_v<value_type, P&&> is true.

    Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

22.5.5.4 Erasure

    template<class K, class T, class H, class P, class A, class Predicate>
    typename unordered_multimap<K, T, H, P, A>::size_type
        erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);

    Effects: Equivalent to:
        auto original_size = c.size();
        for (auto i = c.begin(), last = c.end(); i != last; ) {
            if (pred(*i)) {
                i = c.erase(i);
            } else {
                ++i;
            }
        }
        return original_size - c.size();

22.5.6 Class template unordered_set

22.5.6.1 Overview

An unordered_set is an unordered associative container that supports unique keys (an unordered_set contains at most one of each key value) and in which the elements' keys are the elements themselves. The unordered_set class supports forward iterators.

An unordered_set meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 76). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_set supports the a_uniq operations in that table, not the a_eq operations. For an unordered_set<Key> the key type and the value type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 22.5.6 only describes operations on unordered_set that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
    template<class Key,
        class Hash = hash<Key>,
        class Pred = equal_to<Key>,
        class Allocator = allocator<Key>>
    class unordered_set {
        public:
            // types
            using key_type = Key;
            using value_type = Key;
            using hasher = Hash;
            using key_equal = Pred;
            using allocator_type = Allocator;

  -> unordered_set<iter-value-type<InputIterator>,
    Hash, Pred, Allocator>;

template<class T, class Hash = hash<T>,
    class Pred = equal_to<T>, class Allocator = allocator<T>>
unordered_set(initializer_list<T>, typename see below::size_type = see below,
    Hash = Hash(), Pred = Pred(), Allocator = Allocator())
  -> unordered_set<T, Hash, Pred, Allocator>;

template<class InputIterator, class Allocator>
unordered_set(InputIterator, InputIterator, typename see below::size_type,
    Hash, Alloc)
  -> unordered_set<iter-value-type<InputIterator>,
    hash<iter-value-type<InputIterator>>,
    equal_to<iter-value-type<InputIterator>>,
    Allocator>;

A size_type parameter type in an unordered_set deduction guide refers to the size_type member type of the
type deduced by the deduction guide.

22.5.6.2 Constructors

unordered_set() : unordered_set(size_type(see below)) { }
explicit unordered_set(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),

§ 22.5.6.2
const allocator_type& a = allocator_type();

Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_set(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_set(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

22.5.6.3 Erasure [unord.set.earasure]
template<class K, class H, class P, class A, class Predicate>
type name unordered_set<K, H, P, A>:size_type
erase_if(unordered_set<K, H, P, A>& c, Predicate pred);

Effects: Equivalent to:

auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();

22.5.7 Class template unordered_multiset [unord.multiset]

22.5.7.1 Overview [unord.multiset.overview]

An unordered_multiset is an unordered associative container that supports equivalent keys (an instance of unordered_multiset may contain multiple copies of the same key value) and in which each element’s key is the element itself. The unordered_multiset class supports forward iterators.

An unordered_multiset meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 76). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multiset supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multiset<Key> the key type and the value type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 22.5.7 only describes operations on unordered_multiset that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
    template<class Key,
            class Hash = hash<Key>,
            class Pred = equal_to<Key>,
            class Allocator = allocator<Key>>
    class unordered_multiset {

void swap(unordered_multiset<Key, Hash, Pred, Alloc>& x,
unordered_multiset<Key, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));

A size_type parameter type in an unordered_multiset deduction guide refers to the size_type member type of the type deduced by the deduction guide.

22.5.7.2 Constructors

unordered_multiset() : unordered_multiset(size_type(see below)) {}
explicit unordered_multiset(size_type n,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_multiset(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_multiset(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

22.5.7.3 Erasure

template<class K, class H, class P, class A, class Predicate>
typename unordered_multiset<K, H, P, A>::size_type
erase_if(unordered_multiset<K, H, P, A>& c, Predicate pred);

Effects: Equivalent to:
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
if (pred(*i)) {
    i = c.erase(i);
} else {
    ++i;
}
return original_size - c.size();
22.6 Container adaptors

22.6.1 In general

The headers `<queue>` and `<stack>` define the container adaptors queue, priority_queue, and stack.

The container adaptors each take a Container template parameter, and each constructor takes a Container reference argument. This container is copied into the Container member of each adaptor. If the container takes an allocator, then a compatible allocator may be passed in to the adaptor’s constructor. Otherwise, normal copy or move construction is used for the container argument. The first template parameter T of the container adaptors shall denote the same type as Container::value_type.

For container adaptors, no swap function throws an exception unless that exception is thrown by the swap of the adaptor’s Container or Compare object (if any).

A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:

1. It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
2. It has a Compare template parameter and a type that qualifies as an allocator is deduced for that parameter.
3. It has a Container template parameter and a type that qualifies as an allocator is deduced for that parameter.
4. It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.
5. It has both Container and Allocator template parameters, and uses_allocator_v<Container, Allocator> is false.

22.6.2 Header `<queue>` synopsis

```cpp
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.1
namespace std {
    template<class T, class Container = deque<T>> class queue;
    template<class T, class Container>  
        bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
    template<class T, class Container>  
        bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);

    operator<=>(const stack<T, Container>& x, const stack<T, Container>& y);
    template<class T, class Container, class Alloc>
    struct uses_allocator<stack<T, Container>, Alloc> {
        Container c;
    }
}
```

22.6.4 Class template queue

22.6.4.1 Definition

Any sequence container supporting operations `front()`, `back()`, `push_back()` and `pop_front()` can be used to instantiate queue. In particular, `list` (22.3.10) and `deque` (22.3.8) can be used.

```cpp
namespace std {
    template<class T, class Container = deque<T>> class queue {
        using value_type = typename Container::value_type;
        using reference = typename Container::reference;
        using const_reference = typename Container::const_reference;
        using size_type = typename Container::size_type;
        using container_type = Container;

        public:
            queue() : queue(Container()) {}
            explicit queue(const Container&);
            explicit queue(Container&&);
            template<class Alloc> explicit queue(const Alloc&);
            template<class Alloc> queue(const Container&, const Alloc&);
            template<class Alloc> queue(Container&, const Alloc&);
            template<class Alloc> queue(const queue&, const Alloc&);
            template<class Alloc> queue(queue&&, const Alloc&);

            [[nodiscard]] bool empty() const { return c.empty(); }
            size_type size() const { return c.size(); }
            reference front() { return c.front(); }
            const_reference front() const { return c.front(); }
            reference back() { return c.back(); }
            const_reference back() const { return c.back(); }
    }
```
void push(const value_type& x) { c.push_back(x); }
void push(value_type&& x) { c.push_back(std::move(x)); }

template<class... Args>
decltype(auto) emplace(Args&&... args)
    { return c.emplace_back(std::forward<Args>(args)...); }
void pop() { c.pop_front(); }
void swap(queue& q) noexcept(is_nothrow_swappable_v<Container>)
    { using std::swap; swap(c, q.c); }
};

template<class Container>
queue(Container) -> queue<typename Container::value_type, Container>;

template<class Container, class Allocator>
queue(Container, Allocator) -> queue<typename Container::value_type, Container>;

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

template<class T, class Container, class Alloc>
struct uses_allocator<queue<T, Container>, Alloc>
    : uses_allocator<Container, Alloc>::type { };
template<class T, class Container>
bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( \text{x.c < y.c} \).

3

template<class T, class Container>
bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( \text{x.c > y.c} \).

4

template<class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( \text{x.c <= y.c} \).

5

template<class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( \text{x.c >= y.c} \).

6

template<class T, class Container>
compare_three_way_result_t<Container>
operator<=>(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( \text{x.c <=> y.c} \).

7

22.6.4.5 Specialized algorithms [queue.special]

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

Constraints: \( \text{is_swappable_v<Container>} \) is true.

1

Effects: As if by \( \text{x.swap(y)} \).

2

22.6.5 Class template priority_queue [priority.queue]

22.6.5.1 Overview [priqueue.overview]

Any sequence container with random access iterator and supporting operations \text{front()}, \text{push_back()} and \text{pop_back()} can be used to instantiate \text{priority_queue}. In particular, \text{vector} (22.3.11) and \text{deque} (22.3.8) can be used. Instantiating \text{priority_queue} also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (25.8).

namespace std {
    template<class T, class Container = vector<T>,
             class Compare = less<typename Container::value_type>>
    class priority_queue {
    public:
        using value_type = typename Container::value_type;
        using reference = typename Container::reference;
        using const_reference = typename Container::const_reference;
        using size_type = typename Container::size_type;
        using container_type = Container;
        using value_compare = Compare;

    protected:
        Container c;
        Compare comp;

    public:
        priority_queue() : priority_queue(Compare()) {}
        explicit priority_queue(const Compare& x) : priority_queue(x, Container()) {}
        priority_queue(const Compare& x, const Container&);
        priority_queue(const Compare& x, Container&&);
        template<class InputIterator>
        priority_queue(InputIterator first, InputIterator last, const Compare& x,
                        const Container&);

    § 22.6.5.1
template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last,
                   const Compare& x = Compare(), Container&& y = Container());
template<class Alloc> explicit priority_queue(const Alloc&);

void swap(priority_queue& q) noexcept(is_nothrow_swappable_v<Container> &&
           is_nothrow_swappable_v<Compare>)
    { using std::swap; swap(c, q.c); swap(comp, q.comp); }
};

template<class Compare, class Container>
    priority_queue(Compare, Container)
    -> priority_queue<typename Container::value_type, Container, Compare>;

template<class Compare, class Container, class Allocator>
    priority_queue(Compare, Container, Allocator)
    -> priority_queue<typename Container::value_type, Container, Compare>;

// no equality is provided

template<class T, class Container, class Compare>
    void swap(priority_queue<T, Container, Compare>& x,
              priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

template<class T, class Container, class Compare, class Alloc>
    struct uses_allocator<priority_queue<T, Container, Compare>, Alloc>
    : uses_allocator<Container, Alloc>::type { }

22.6.5.2 Constructors
[priqueue.cons]

priority_queue(const Compare& x, const Container& y);
priority_queue(const Compare& x, Container& y);

1 Preconditions: x defines a strict weak ordering (25.8).

2 Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate); calls
   make_heap(c.begin(), c.end(), comp).

template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x, const Container& y);
template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare(),
                    Container& y = Container());

3 Preconditions: x defines a strict weak ordering (25.8).
22.6.5.3 Constructors with allocators

If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

```
template<class Alloc> explicit priority_queue(const Alloc& a);
```

**Effects:** Initializes c with a and value-initializes comp.

```
template<class Alloc> priority_queue(const Compare& compare, const Alloc& a);
```

**Effects:** Initializes c with a and initializes comp with compare.

```
template<class Alloc>
    priority_queue(const Compare& compare, const Container& cont, const Alloc& a);
```

**Effects:** Initializes c with cont as the first argument and a as the second argument, and initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).

```
template<class Alloc>
    priority_queue(const Compare& compare, Container&& cont, const Alloc& a);
```

**Effects:** Initializes c with std::move(cont) as the first argument and a as the second argument, and initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).

```
template<class Alloc>
    priority_queue(const priority_queue& q, const Alloc& a);
```

**Effects:** Initializes c with q.c as the first argument and a as the second argument, and initializes comp with q.comp.

```
template<class Alloc> priority_queue(priority_queue&& q, const Alloc& a);
```

**Effects:** Initializes c with std::move(q.c) as the first argument and a as the second argument, and initializes comp with std::move(q.comp).

22.6.5.4 Members

```
void push(const value_type& x);
```

**Effects:** As if by:

```
c.push_back(x);
push_heap(c.begin(), c.end(), comp);
```

```
void push(value_type&& x);
```

**Effects:** As if by:

```
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);
```

```
template<class... Args> void emplace(Args&&... args);
```

**Effects:** As if by:

```
c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);
```

```
void pop();
```

**Effects:** As if by:

```
pop_heap(c.begin(), c.end(), comp);
c.pop_back();
```

22.6.5.5 Specialized algorithms

```
template<class T, class Container, class Compare>
    void swap(priority_queue<T, Container, Compare>& x,
              priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));
```

**Constraints:** is_swappable_v<Container> is true and is_swappable_v<Compare> is true.
22.6.6 Class template stack

Any sequence container supporting operations `back()`, `push_back()` and `pop_back()` can be used to instantiate stack. In particular, `vector` (22.3.11), `list` (22.3.10) and `deque` (22.3.8) can be used.

22.6.6.1 Definition

```cpp
namespace std {
    template<class T, class Container = deque<T>>
    class stack {
        public:
            using value_type = typename Container::value_type;
            using reference = typename Container::reference;
            using const_reference = typename Container::const_reference;
            using size_type = typename Container::size_type;
            using container_type = Container;
        protected:
            Container c;
        public:
            stack() : stack(Container()) {}
            explicit stack(const Container&);
            explicit stack(Container&&);
            template<class Alloc> explicit stack(const Alloc&);
            template<class Alloc> stack(const Container&, const Alloc&);
            template<class Alloc> stack(Container&&, const Alloc&);
            template<class Alloc> stack(const stack&, const Alloc&);
            template<class Alloc> stack(stack&&, const Alloc&);
            [[nodiscard]] bool empty() const { return c.empty(); }
            size_type size() const { return c.size(); }
            reference top() { return c.back(); }
            const_reference top() const { return c.back(); }
            void push(const value_type& x) { c.push_back(x); }
            void push(value_type&& x) { c.push_back(std::move(x)); }
            template<class... Args>
                decltype(auto) emplace(Args&&... args)
                { return c.emplace_back(std::forward<Args>(args)...); }
            void pop() { c.pop_back(); }
            void swap(stack& s) noexcept(is_nothrow_swappable_v<Container>)
                { using std::swap; swap(c, s.c); }
        }
    };
    template<class Container>
    stack(Container) -> stack<typename Container::value_type, Container>;
    template<class Container, class Allocator>
    stack(Container, Allocator) -> stack<typename Container::value_type, Container>;
    template<class T, class Container, class Alloc>
    struct uses_allocator<stack<T, Container>, Alloc>
        : uses_allocator<Container, Alloc>::type {};
}
```

22.6.6.2 Constructors

```
explicit stack(const Container& cont);

explicit stack(Container&& cont);
```

1 Effects: Initializes c with cont.

2 Effects: Initializes c with std::move(cont).
22.6.6.3 Constructors with allocators

If `uses_allocator_v<container_type, Alloc>` is false the constructors in this subclause shall not participate in overload resolution.

```cpp
template<class Alloc> explicit stack(const Alloc& a);
```

**Effects:** Initializes `c` with `a`.

```cpp
template<class Alloc> stack(const container_type& cont, const Alloc& a);
```

**Effects:** Initializes `c` with `cont` as the first argument and `a` as the second argument.

```cpp
template<class Alloc> stack(container_type&& cont, const Alloc& a);
```

**Effects:** Initializes `c` with `std::move(cont)` as the first argument and `a` as the second argument.

```cpp
template<class Alloc> stack(const stack& s, const Alloc& a);
```

**Effects:** Initializes `c` with `s.c` as the first argument and `a` as the second argument.

```cpp
template<class Alloc> stack(stack&& s, const Alloc& a);
```

**Effects:** Initializes `c` with `std::move(s.c)` as the first argument and `a` as the second argument.

22.6.6.4 Operators

```cpp
template<class T, class Container>
bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
```

**Returns:** `x.c == y.c`.

```cpp
template<class T, class Container>
bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
```

**Returns:** `x.c != y.c`.

```cpp
template<class T, class Container>
bool operator< (const stack<T, Container>& x, const stack<T, Container>& y);
```

**Returns:** `x.c < y.c`.

```cpp
template<class T, class Container>
bool operator> (const stack<T, Container>& x, const stack<T, Container>& y);
```

**Returns:** `x.c > y.c`.

```cpp
template<class T, class Container>
bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);
```

**Returns:** `x.c <= y.c`.

```cpp
template<class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
```

**Returns:** `x.c >= y.c`.

```cpp
template<class T, three_way_comparable Container>
compare_three_way_result_t<Container>
operator<=>(const stack<T, Container>& x, const stack<T, Container>& y);
```

**Returns:** `x.c <=> y.c`.

22.6.6.5 Specialized algorithms

```cpp
template<class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));
```

**Constraints:** `is_swappable_v<Container>` is true.

**Effects:** As if by `x.swap(y)`.

§ 22.6.6.5
22.7 Views

22.7.1 General

The header `<span>` defines the view span.

22.7.2 Header `<span>` synopsis

namespace std {

// constants
inline constexpr size_t dynamic_extent = numeric_limits<size_t>::max();

// 22.7.3, class template `span`
template<class ElementType, size_t Extent = dynamic_extent>
class span;

template<class ElementType, size_t Extent>
inline constexpr bool ranges::enable_view<span<ElementType, Extent>> =
Extent == 0 || Extent == dynamic_extent;
template<class ElementType, size_t Extent>
inline constexpr bool ranges::enable_borrowed_range<span<ElementType, Extent>> = true;

// 22.7.3.8, views of object representation
template<class ElementType, size_t Extent>
span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_bytes(span<ElementType, Extent> s) noexcept;
template<class ElementType, size_t Extent>
span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_writable_bytes(span<ElementType, Extent> s) noexcept;
}

22.7.3 Class template `span`

22.7.3.1 Overview

A span is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

All member functions of `span` have constant time complexity.

namespace std {

// constants and types
using element_type = ElementType;
using value_type = remove_cv_t<ElementType>;
using size_type = size_t;
using difference_type = ptrdiff_t;
using pointer = element_type*;
using const_pointer = const element_type*;
using reference = element_type&;
using const_reference = const element_type&;
using iterator = implementation-defined; // see 22.7.3.7
static constexpr size_type extent = Extent;

// 22.7.3.2, constructors, copy, and assignment
constexpr span() noexcept;
template<class It>
constexpr explicit(extent != dynamic_extent) span(It first, size_type count);
template<class It, class End>
constexpr explicit(extent != dynamic_extent) span(It first, End last);
template<size_t N>
constexpr span(type_identity_t<element_type>(&arr)[N]) noexcept;
template<class T, size_t N>
constexpr span(array<T, N>& arr) noexcept;

§ 22.7.3.1 873
template<class T, size_t N>
    constexpr span(const array<T, N>& arr) noexcept;

template<class R>
    constexpr explicit(span(R&& r));

constexpr span(const span& other) noexcept = default;

template<class OtherElementType, size_t OtherExtent>
    constexpr explicit(span<const OtherElementType, OtherExtent>& s) noexcept;

~span() noexcept = default;

constexpr span& operator=(const span& other) noexcept = default;

// 22.7.3.4, subviews
template<size_t Count>
    constexpr span<element_type, Count> first() const;

template<size_t Count>
    constexpr span<element_type, Count> last() const;

template<size_t Offset, size_t Count = dynamic_extent>
    constexpr span<element_type, dynamic_extent> subspan() const;

constexpr span<element_type, dynamic_extent> first(size_type count) const;

constexpr span<element_type, dynamic_extent> last(size_type count) const;

constexpr span<element_type, dynamic_extent> subspan(
    size_type offset, size_type count = dynamic_extent) const;

// 22.7.3.5, observers
constexpr size_type size() const noexcept;

constexpr size_type size_bytes() const noexcept;

[[nodiscard]] constexpr bool empty() const noexcept;

// 22.7.3.6, element access
constexpr reference operator[](size_type idx) const;

constexpr reference front() const;

constexpr reference back() const;

constexpr pointer data() const noexcept;

// 22.7.3.7, iterator support
constexpr iterator begin() const noexcept;

constexpr iterator end() const noexcept;

constexpr reverse_iterator rbegin() const noexcept;

constexpr reverse_iterator rend() const noexcept;

private:
    pointer data_; // exposition only
    size_type size_; // exposition only
};

template<class It, class EndOrSize>
    span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>>;

template<class T, size_t N>
    span(T (&)[N]) -> span<T, N>;

template<class T, size_t N>
    span(array<T, N>&) -> span<T, N>;

template<class T, size_t N>
    span(const array<T, N>&) -> span<const T, N>;

template<class R>
    span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;

3 ElementType is required to be a complete object type that is not an abstract class type.
22.7.3.2 Constructors, copy, and assignment

```cpp
constexpr span() noexcept;

Constraints: Extent == dynamic_extent || Extent == 0 is true.
Postconditions: size() == 0 && data() == nullptr.
```

```cpp
template<class It>
constexpr explicit(extent != dynamic_extent) span(It first, size_type count);
```

```cpp
Constraints: Let U be remove_reference_t<iter_reference_t<It>>.
(3.1) It satisfies contiguous_iterator.
(3.2) is_convertible_v<U(*)[], element_type(*)[]> is true. [Note: The intent is to allow only qualification conversions of the iterator reference type to element_type. — end note]
```

```cpp
Preconditions:
(4.1) [first, first + count) is a valid range.
(4.2) It models contiguous_iterator.
(4.3) If extent is not equal to dynamic_extent, then count is equal to extent.
```

```cpp
Effects: Initializes data_ with to_address(first) and size_ with count.
```

```cpp
Throws: Nothing.
```

```cpp
template<class It, class End>
constexpr explicit(extent != dynamic_extent) span(It first, End last);
```

```cpp
Constraints: Let U be remove_reference_t<iter_reference_t<It>>.
(7.1) is_convertible_v<U(*)[], element_type(*)[]> is true. [Note: The intent is to allow only qualification conversions of the iterator reference type to element_type. — end note]
(7.2) It satisfies contiguous_iterator.
(7.3) End satisfies sized_sentinel_for<It>.
(7.4) is_convertible_v<End, size_t> is false.
```

```cpp
Preconditions:
(8.1) If extent is not equal to dynamic_extent, then last - first is equal to extent.
(8.2) [first, last) is a valid range.
(8.3) It models contiguous_iterator.
(8.4) End models sized_sentinel_for<It>.
```

```cpp
Effects: Initializes data_ with to_address(first) and size_ with last - first.
```

```cpp
Throws: When and what last - first throws.
```

```cpp
template<size_t N> constexpr span(type_identity_t<element_type> (&arr)[N]) noexcept;
```

```cpp
template<class T, size_t N> constexpr span(array<T, N>& arr) noexcept;
```

```cpp
template<class T, size_t N> constexpr span(const array<T, N>& arr) noexcept;
```

```cpp
Constraints: Let U be remove_pointer_t<decltype(data(arr))>.
(11.1) extent == dynamic_extent || N == extent is true, and
(11.2) is_convertible_v<U(*)[], element_type(*)[]> is true. [Note: The intent is to allow only qualification conversions of the array element type to element_type. — end note]
```

```cpp
Effects: Constructs a span that is a view over the supplied array. [Note: type_identity_t affects class template argument deduction. — end note]
```

```cpp
Postconditions: size() == N && data() == data(arr) is true.
```

```cpp
template<class R> constexpr explicit(extent != dynamic_extent) span(R&& r);
```

```cpp
Constraints: Let U be remove_reference_t<ranges::range_reference_t<R>>.
(14.1) R satisfies ranges::contiguous_range and ranges::sized_range.
(14.2) Either R satisfies ranges::borrowed_range or is_const_v<element_type> is true.
```
--- remove_cvref_t<R> is not a specialization of span.
--- remove_cvref_t<R> is not a specialization of array.
--- is_array_v<remove_cvref_t<R>> is false.
--- is_convertible_v<U(*)[], element_type(*)[]> is true. [Note: The intent is to allow only qualification conversions of the range reference type to element_type. — end note]

Preconditions:

(15.1) If extent is not equal to dynamic_extent, then ranges::size(r) is equal to extent.
(15.2) R models ranges::contiguous_range and ranges::sized_range.
(15.3) If is_const_v<element_type> is false, R models ranges::borrowed_range.

Effects: Initializes data_with ranges::data(r) and size_with ranges::size(r).

Throws: What and when ranges::data(r) and ranges::size(r) throw.

cconstexpr span(const span& other) noexcept = default;
Postconditions: other.size() == size() & other.data() == data().

template<class OtherElementType, size_t OtherExtent>
cconstexpr explicit(see below) span(const span<OtherElementType, OtherExtent>& s) noexcept;
Constraints:

(19.1) extent == dynamic_extent || OtherExtent == dynamic_extent || extent == OtherExtent is true, and
(19.2) is_convertible_v<OtherElementType(*)[], element_type(*)[]> is true. [Note: The intent is to allow only qualification conversions of the OtherElementType to element_type. — end note]

Preconditions: If extent is not equal to dynamic_extent, then s.size() is equal to extent.

Postconditions: size() == s.size() & data() == s.data().

Remarks: The expression inside explicit is equivalent to:

extent != dynamic_extent & OtherExtent == dynamic_extent

constexpr span operator=(const span& other) noexcept = default;
Postconditions: size() == other.size() & data() == other.data().

22.7.3.3 Deduction guides

template<class It, class EndOrSize>
span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>>;
Constraints: It satisfies contiguous_iterator.

template<class R>
span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;
Constraints: R satisfies ranges::contiguous_range.

22.7.3.4 Subviews

template<size_t Count> constexpr span<element_type, Count> first() const;
Mandates: Count <= Extent is true.
Preconditions: Count <= size() is true.
Effects: Equivalent to: return R(data(), Count); where R is the return type.

template<size_t Count> constexpr span<element_type, Count> last() const;
Mandates: Count <= Extent is true.
Preconditions: Count <= size() is true.
Effects: Equivalent to: return R(data() + (size() - Count), Count); where R is the return type.
template<
    size_t Offset, size_t Count = dynamic_extent>
constexpr span<element_type, see below> subspan() const;

Mandates:
Offset <= Extent && (Count == dynamic_extent || Count <= Extent - Offset)
is true.

Preconditions:
Offset <= size() && (Count == dynamic_extent || Count <= size() - Offset)
is true.

Effects: Equivalent to:
return span<ElementType, see below>(
data() + Offset, Count != dynamic_extent ? Count : size() - Offset);

Remarks: The second template argument of the returned span type is:
Count != dynamic_extent ? Count
: (Extent != dynamic_extent ? Extent - Offset : dynamic_extent)

constexpr span<element_type, dynamic_extent> first(size_type count) const;

Preconditions: count <= size() is true.

Effects: Equivalent to: return {data(), count};

constexpr span<element_type, dynamic_extent> last(size_type count) const;

Preconditions: count <= size() is true.

Effects: Equivalent to: return {data() + (size() - count), count};

constexpr span<element_type, dynamic_extent> subspan(
    size_type offset, size_type count = dynamic_extent) const;

Preconditions:
offset <= size() && (count == dynamic_extent || count <= size() - offset)
is true.

Effects: Equivalent to:
return {data() + offset, count == dynamic_extent ? size() - offset : count};

22.7.3.5 Observers [span.obs]

constexpr size_type size() const noexcept;

Effects: Equivalent to: return size_;

constexpr size_type size_bytes() const noexcept;

Effects: Equivalent to: return size() * sizeof(element_type);

[[nodiscard]] constexpr bool empty() const noexcept;

Effects: Equivalent to: return size() == 0;

22.7.3.6 Element access [span.elem]

constexpr reference operator[](size_type idx) const;

Preconditions: idx < size() is true.

Effects: Equivalent to: return *(data() + idx);

constexpr reference front() const;

Preconditions: empty() is false.

Effects: Equivalent to: return *data();
constexpr reference back() const;

Preconditions: empty() is false.

Effects: Equivalent to: return *(data() + (size() - 1));

constexpr pointer data() const noexcept;

Effects: Equivalent to: return data_;

22.7.3.7 Iterator support

using iterator = implementation-defined;

The type models contiguous_iterator (23.3.4.14), meets the Cpp17RandomAccessIterator requirements (23.3.5.6), and meets the requirements for constexpr iterators (23.3.1), whose value type is value_type and whose reference type is reference.

All requirements on container iterators (22.2) apply to span::iterator as well.

constexpr iterator begin() const noexcept;

Returns: An iterator referring to the first element in the span. If empty() is true, then it returns the same value as end().

constexpr iterator end() const noexcept;

Returns: An iterator which is the past-the-end value.

constexpr reverse_iterator rbegin() const noexcept;

Effects: Equivalent to: return reverse_iterator(end());

constexpr reverse_iterator rend() const noexcept;

Effects: Equivalent to: return reverse_iterator(begin());

22.7.3.8 Views of object representation

template<class ElementType, size_t Extent>
span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_bytes(span<ElementType, Extent> s) noexcept;

Effects: Equivalent to: return R{reinterpret_cast<const byte*>(s.data()), s.size_bytes()}; where R is the return type.

template<class ElementType, size_t Extent>
span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_writable_bytes(span<ElementType, Extent> s) noexcept;

Constraints: is_const_v<ElementType> is false.

Effects: Equivalent to: return R{reinterpret_cast<byte*>(s.data()), s.size_bytes()}; where R is the return type.
23 Iterators library

23.1 General

This Clause describes components that C++ programs may use to perform iterations over containers (Clause 22),
streams (29.7), stream buffers (29.6), and other ranges (Clause 24).

The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators,
and stream iterators, as summarized in Table 82.

Table 82: Iterators library summary

23.3 Iterator requirements

23.3.1 In general

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (for example, containers and ranges) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. An input iterator i supports the expression *i, resulting in a value of some object type T, called the value type of the iterator. An output iterator i has a non-empty set of types that are indirectly writable to the iterator; for each such type T, the expression *i = o is valid where o is a value of type T. For every iterator type X, there is a corresponding signed integer-like type (23.3.4.4) called the difference type of the iterator.

Since iterators are an abstraction of pointers, their semantics are a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This document defines six categories of iterators, according to the operations defined on them: input iterators, output iterators, forward iterators, bidirectional iterators, random access iterators, and contiguous iterators, as shown in Table 83.

| Contiguous → Random Access → Bidirectional → Forward → Input → Output |

The six categories of iterators correspond to the iterator concepts:

1. input_iterator (23.3.4.9),
2. output_iterator (23.3.4.10),
3. forward_iterator (23.3.4.11),
4. bidirectional_iterator (23.3.4.12),
5. random_access_iterator (23.3.4.13), and
6. contiguous_iterator (23.3.4.14), respectively. The generic term iterator refers to any type that models the input_or_output_iterator concept (23.3.4.6).

Forward iterators meet all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also meet all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also meet all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified; Contiguous iterators also meet all the requirements of random access iterators and can be used whenever a random access iterator is specified.

5. Iterators that further meet the requirements of output iterators are called mutable iterators. Nonmutable iterators are referred to as constant iterators.

6. In addition to the requirements in this subclause, the nested typedef-names specified in 23.3.2.3 shall be provided for the iterator type. [Note: Either the iterator type must provide the typedef-names directly (in which case iterator_traits pick them up automatically), or an iterator_traits specialization must provide them. — end note]

7. Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. Such a value is called a past-the-end value. Values of an iterator i for which the expression *i is defined are called dereferenceable. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. [Example: After the declaration of an uninitialized pointer x (as with int* x);, x must always be assumed to have a singular value of a pointer. — end example] Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value, the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that meet the Cpp17DefaultConstructible requirements, using a value-initialized iterator as the source of a copy or move operation. [Note: This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. — end note] In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

§ 23.3.1

886
Most of the library’s algorithmic templates that operate on data structures have interfaces that use ranges. A range is an iterator and a sentinel that designate the beginning and end of the computation, or an iterator and a count that designate the beginning and the number of elements to which the computation is to be applied.\footnote{The sentinel denoting the end of a range may have the same type as the iterator denoting the beginning of the range, or a different type.}

An iterator and a sentinel denoting a range are comparable. A range \([i, s)\) is empty if \(i == s\); otherwise, \([i, s)\) refers to the elements in the data structure starting with the element pointed to by \(i\) and up to but not including the element, if any, pointed to by the first iterator \(j\) such that \(j == s\).

A sentinel \(s\) is called reachable from an iterator \(i\) if and only if there is a finite sequence of applications of the expression \(++i\) that makes \(i == s\). If \(s\) is reachable from \(i\), \([i, s)\) denotes a valid range.

A counted range \(i + [0, n)\) is empty if \(n == 0\); otherwise, \(i + [0, n)\) refers to the \(n\) elements in the data structure starting with the element pointed to by \(i\) and up to but not including the element, if any, pointed to by the result of \(n\) applications of \(++i\). A counted range \(i + [0, n)\) is valid if and only if \(n == 0\); or \(n\) is positive, \(i\) is dereferenceable, and \(++i + [0, --n)\) is valid.

The result of the application of library functions to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables and concept definitions for the iterators do not specify complexity.

Destruction of a non-forward iterator may invalidate pointers and references previously obtained from that iterator.

An invalid iterator is an iterator that may be singular.\footnote{This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.}

Iterators are called constexpr iterators if all operations provided to meet iterator category requirements are constexpr functions. \[Note: For example, the types “pointer to int” and reverse_iterator<int*> are constexpr iterators. \— end note\]

### 23.3.2 Associated types

#### 23.3.2.1 Incrementable traits

To implement algorithms only in terms of incrementable types, it is often necessary to determine the difference type that corresponds to a particular incrementable type. Accordingly, it is required that if \(\texttt{WI}\) is the name of a type that models the weakly_incrementable concept (23.3.4.4), the type

\[
\texttt{iter_difference_t<\texttt{WI}>}
\]

be defined as the incrementable type’s difference type.

```
namespace std {
    template<class> struct incrementable_traits { }

    template<class T>
    requires is_object_v<T>
    struct incrementable_traits<T*> {
        using difference_type = ptrdiff_t;
    }

    template<class I>
    struct incrementable_traits<const I> : incrementable_traits<I> { }

    template<class T>
    requires requires { typename T::difference_type; }
    struct incrementable_traits<T> {
        using difference_type = typename T::difference_type;
    }

    template<class T>
    requires (requires { typename T::difference_type; } &&
    requires(const T& a, const T& b) { { a - b } -> integral; })
    struct incrementable_traits<T> {
        using difference_type = make_signed_t<decltype(declval<T>() - declval<T>())>;
    }
```

\[§ 23.3.2.1\]
template<class T>  
    using iter_difference_t = see below;

Let \( R_I \) be \( \text{remove_cvref}_t\langle I \rangle \). The type \( \text{iter_difference}_t\langle I \rangle \) denotes

(2.1) \(-\) \( \text{incrementable_traits}\langle R_I \rangle::\text{difference_type} \) if \( \text{iterator_traits}\langle R_I \rangle \) names a specialization generated from the primary template, and

(2.2) \(-\) \( \text{iterator_traits}\langle R_I \rangle::\text{difference_type} \) otherwise.

Users may specialize \( \text{incrementable_traits} \) on program-defined types.

### 23.3.2.2 Indirectly readable traits

To implement algorithms only in terms of indirectly readable types, it is often necessary to determine the value type that corresponds to a particular indirectly readable type. Accordingly, it is required that if \( R \) is the name of a type that models the \text{indirectly_readable} concept (23.3.4.2), the type

\[ \text{iter_value}_t\langle R \rangle \]

be defined as the indirectly readable type’s value type.

```
template<class> struct cond_value_type { }; // exposition only
template<class T>  
    requires is_object_v<T>  
    struct cond_value_type<T> {  
        using value_type = remove_cv_t<T>;  
    };

template<class T>  
    struct indirectly_readable_traits<T>  
    : cond_value_type<T> { };

template<class I>  
    requires is_array_v<I>  
    struct indirectly_readable_traits<I> {  
        using value_type = remove_cv_t<remove_extent_t<I>>;  
    };

template<class I>  
    struct indirectly_readable_traits<const I>  
    : indirectly_readable_traits<I> { };

template<class T>  
    requires requires { typename T::value_type; }  
    struct indirectly_readable_traits<T>  
    : cond_value_type<typename T::value_type> { };

template<class T>  
    requires requires { typename T::element_type; }  
    struct indirectly_readable_traits<T>  
    : cond_value_type<typename T::element_type> { };

template<class T> using iter_value_t = see below;

Let \( R_I \) be \( \text{remove_cvref}_t\langle I \rangle \). The type \( \text{iter_value}_t\langle I \rangle \) denotes

(2.1) \(-\) \( \text{indirectly_readable_traits}\langle R_I \rangle::\text{value_type} \) if \( \text{iterator_traits}\langle R_I \rangle \) names a specialization generated from the primary template, and

(2.2) \(-\) \( \text{iterator_traits}\langle R_I \rangle::\text{value_type} \) otherwise.

Class template \( \text{indirectly_readable_traits} \) may be specialized on program-defined types.

[Note: Some legacy output iterators define a nested type named \text{value_type} that is an alias for void. These types are not \text{indirectly_readable} and have no associated value types. — end note]
[Note: Smart pointers like `shared_ptr<int>` are indirectly_readable and have an associated value type, but a smart pointer like `shared_ptr<void>` is not indirectly_readable and has no associated value type. — end note]

### 23.3.2.3 Iterator traits

To implement algorithms only in terms of iterators, it is sometimes necessary to determine the iterator category that corresponds to a particular iterator type. Accordingly, it is required that if `I` is the type of an iterator, the type

```
iterator_traits<I>::iterator_category
```

be defined as the iterator’s iterator category. In addition, the types

```
iterator_traits<I>::pointer
iterator_traits<I>::reference
```

shall be defined as the iterator’s pointer and reference types; that is, for an iterator object `a` of class type, the same type as `decltype(a.operator->())` and `decltype(*a)`, respectively. The type `iterator_traits<I>::pointer` shall be void for an iterator of class type `I` that does not support `operator->`. Additionally, in the case of an output iterator, the types

```
iterator_traits<I>::value_type
iterator_traits<I>::difference_type
iterator_traits<I>::reference
```

may be defined as void.

2 The definitions in this subclause make use of the following exposition-only concepts:

```cpp
template<class I>
concept cpp17-iterator =
    copyable<I> && requires(I i) {
        { *i } -> can-reference;
        { ++i } -> same_as<I&>;
        { *i++ } -> can-reference;
    };

template<class I>
concept cpp17-input-iterator =
    cpp17-iterator<I> && equality_comparable<I> && requires(I i) {
        typename incrementable_traits<I>::difference_type;
        typename indirectly_readable_traits<I>::value_type;
        typename common_reference_t<iter_reference_t<I>&&,
            typename indirectly_readable_traits<I>::value_type&>
            typename common_reference_t<decltype(*i++)&&,
                typename indirectly_readable_traits<I>::value_type&>;
        requires signed_integral<typename incrementable_traits<I>::difference_type>;
    };

template<class I>
concept cpp17-forward-iterator =
    cpp17-input-iterator<I> && constructible_from<I> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<remove_cvref_t<iter_reference_t<I>>,
        typename indirectly_readable_traits<I>::value_type> &&
    requires(I i) {
        { i++ } -> convertible_to<const I&>;
        { *i++ } -> same_as<iter_reference_t<I>>;
    };

template<class I>
concept cpp17-bidirectional-iterator =
    cpp17-forward-iterator<I> && requires(I i) {
        { --i } -> same_as<I&>;
        { i-- } -> convertible_to<const I&>;
        { *i-- } -> same_as<iter_reference_t<I>>;
    };
```
template<class I>
concept cpp17-random-access-iterator =
    cpp17-bidirectional-iterator<I> && totally_ordered<I> &&
requires(I i, typename incrementable_traits<I>::difference_type n) {
    { i += n } -> same_as<I&>;
    { i -= n } -> same_as<I&>;
    { n + i } -> same_as<I>;
    { i < n } -> same_as<I>;
    { i == n } -> same_as<iter_reference_t<I>>;
};

The members of a specialization iterator_traits<I> generated from the iterator_traits primary template are computed as follows:

1. If I has valid (13.10.2) member types difference_type, value_type, reference, and iterator_category, then iterator_traits<I> has the following publicly accessible members:

   using iterator_category = typename I::iterator_category;
   using value_type = typename I::value_type;
   using difference_type = typename I::difference_type;
   using pointer = see below;
   using reference = typename I::reference;

   If the qualified-id I::pointer is valid and denotes a type, then iterator_traits<I>::pointer names that type; otherwise, it names void.

2. Otherwise, if I satisfies the exposition-only concept cpp17-input-iterator, iterator_traits<I> has the following publicly accessible members:

   using iterator_category = see below;
   using value_type = typename indirectly_readable_traits<I>::value_type;
   using difference_type = typename incrementable_traits<I>::difference_type;
   using pointer = see below;
   using reference = see below;

   (3.2.1) — If the qualified-id I::pointer is valid and denotes a type, pointer names that type. Otherwise, if decltype(declval<I&>().operator->()) is well-formed, then pointer names that type. Otherwise, pointer names void.

   (3.2.2) — If the qualified-id I::reference is valid and denotes a type, reference names that type. Otherwise, reference names iter_reference_t<I>.

   (3.2.3) — If the qualified-id I::iterator_category is valid and denotes a type, iterator_category names that type. Otherwise, iterator_category names:

       — random_access_iterator_tag if I satisfies cpp17-random-access-iterator, or otherwise
       — bidirectional_iterator_tag if I satisfies cpp17-bidirectional-iterator, or otherwise
       — forward_iterator_tag if I satisfies cpp17-forward_iterator, or otherwise
       — input_iterator_tag.

   (3.3) — Otherwise, if I satisfies the exposition-only concept cpp17-iterator, then iterator_traits<I> has the following publicly accessible members:

       using iterator_category = output_iterator_tag;
       using value_type = void;
       using difference_type = see below;
       using pointer = void;
       using reference = void;

       If the qualified-id incrementable_traits<I>::difference_type is valid and denotes a type, then difference_type names that type; otherwise, it names void.

   (3.4) — Otherwise, iterator_traits<I> has no members by any of the above names.

Explicit or partial specializations of iterator_traits may have a member type iterator_concept that is used to indicate conformance to the iterator concepts (23.3.4).

iterator_traits is specialized for pointers as
namespace std {
  template<class T>
  requires is_object_v<T>
  struct iterator_traits<T*> {
    using iterator_concept = contiguous_iterator_tag;
    using iterator_category = random_access_iterator_tag;
    using value_type = remove_cv_t<T>;
    using difference_type = ptrdiff_t;
    using pointer = T*;
    using reference = T&;
  };
}

Example: To implement a generic reverse function, a C++ program can do the following:

```cpp
template<class BI>
void reverse(BI first, BI last) {
  typename iterator_traits<BI>::difference_type n = distance(first, last);
  --n;
  while(n > 0) {
    typename iterator_traits<BI>::value_type tmp = *first;
    *first++ = *--last;
    *last = tmp;
    n -= 2;
  }
}
```

— end example

23.3.3 Customization point objects

23.3.3.1 ranges::iter_move

The name ranges::iter_move denotes a customization point object (16.4.2.2.6). The expression ranges::iter_move(E) for a subexpression E is expression-equivalent to:

1. `iter_move(E), if E has class or enumeration type and iter_move(E) is a well-formed expression when treated as an unevaluated operand, with overload resolution performed in a context that does not include a declaration of ranges::iter_move but does include the declaration
   ```cpp
   void iter_move();
   ```
2. Otherwise, if the expression *E is well-formed:
   1. If *E is an lvalue, std::move(*E);
   2. Otherwise, *E.
3. Otherwise, ranges::iter_move(E) is ill-formed. [Note: This case can result in substitution failure when ranges::iter_move(E) appears in the immediate context of a template instantiation. — end note]

If ranges::iter_move(E) is not equal to *E, the program is ill-formed, no diagnostic required.

23.3.3.2 ranges::iter_swap

The name ranges::iter_swap denotes a customization point object (16.4.2.2.6) that exchanges the values (18.4.9) denoted by its arguments.

Let iter-exchange-move be the exposition-only function:

```cpp
template<class X, class Y>
constexpr iter_value_t<X> iter-exchange-move(X&& x, Y&& y)
noexcept(noexcept(iter_value_t<X>(iter_move(x))) &&
  noexcept(*x = iter_move(y)));
```

Effects: Equivalent to:

```cpp
iter_value_t<X> old_value(iter_move(x));
*x = iter_move(y);
return old_value;
```
The expression `ranges::iter_swap(E1, E2)` for subexpressions `E1` and `E2` is expression-equivalent to:

- (void) `iter_swap(E1, E2)`, if either `E1` or `E2` has class or enumeration type and `iter_swap(E1, E2)` is a well-formed expression with overload resolution performed in a context that includes the declaration

  ```cpp
template<class I1, class I2>
void iter_swap(I1, I2) = delete;
```

and does not include a declaration of `ranges::iter_swap`. If the function selected by overload resolution does not exchange the values denoted by `E1` and `E2`, the program is ill-formed, no diagnostic required.

- Otherwise, if the types of `E1` and `E2` each model `indirectly_readable`, and if the reference types of `E1` and `E2` model `swappable_with` (18.4.9), then `ranges::swap(*E1, *E2)`.

- Otherwise, if the types `T1` and `T2` of `E1` and `E2` model `indirectly_movable_storable<T1, T2>` and `indirectly_movable_storable<T2, T1>`, then (void)`(*E1 = iter-exchange-move(E2, E1))`, except that `E1` is evaluated only once.

- Otherwise, `ranges::iter_swap(E1, E2)` is ill-formed. [Note: This case can result in substitution failure when `ranges::iter_swap(E1, E2)` appears in the immediate context of a template instantiation. — end note]
Given a value \( i \) of type \( I \), \( I \) models indirectly_readable only if the expression \( *i \) is equality-preserving. [Note: The expression \( *i \) is indirectly required to be valid via the exposition-only dereferenceable concept (23.2). — end note]

23.3.4.3 Concept indirectly_writable

The indirectly_writable concept specifies the requirements for writing a value into an iterator’s referenced object.

```cpp
template<class Out, class T>
concept indirectly_writable =
requires(Out&& o, T&& t) {
  *o = std::forward<T>(t);  // not required to be equality-preserving
  *std::forward<Out>(o) = std::forward<T>(t);  // not required to be equality-preserving
  const_cast<const iter_reference_t<Out>&&>(*o) =
    std::forward<T>(t);  // not required to be equality-preserving
  const_cast<const iter_reference_t<Out>&&>(*std::forward<Out>(o)) =
    std::forward<T>(t);  // not required to be equality-preserving
};
```

Let \( E \) be an expression such that `decltype((E))` is \( T \), and let \( o \) be a dereferenceable object of type \( Out \). \( Out \) and \( T \) model indirectly_writable\(\langle Out, T \rangle \) only if

1. If \( Out \) and \( T \) model indirectly_readable\(\langle Out \rangle \) && same_as<iter_value_t<Out>, decay_t<T>>, then \( *o \) after any above assignment is equal to the value of \( E \) before the assignment.
2. After evaluating any above assignment expression, \( o \) is not required to be dereferenceable.
3. If \( E \) is an xvalue (7.2.1), the resulting state of the object it denotes is valid but unspecified (16.5.5.16).
4. [Note: The only valid use of an operator* is on the left side of the assignment statement. Assignment through the same value of the indirectly writable type happens only once. — end note]
5. [Note: indirectly_writable has the awkward const_cast expressions to reject iterators with prvalue non-proxy reference types that permit rvalue assignment but do not also permit const rvalue assignment. Consequently, an iterator type \( I \) that returns `std::string` by value does not model indirectly_writable\(\langle I, std::string \rangle \). — end note]

23.3.4.4 Concept weakly_incrementable

The weakly_incrementable concept specifies the requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are not required to be equality-preserving, nor is the type required to be equality_comparable.

```cpp
template<class T>
inline constexpr bool is-integer-like = see below;  // exposition only

template<class T>
inline constexpr bool is-signed-integer-like = see below;  // exposition only

template<class I>
concept weakly_incrementable =
  default_initializable<I> && movable<I> &&
  requires(I i) {
    typename iter_difference_t<I>;
    requires is-signed-integer-like<iter_difference_t<I>>;
    { ++i } -> same_as<I&>;  // not required to be equality-preserving
    i++;                     // not required to be equality-preserving
  };
```

§ 23.3.4.4
A type \( I \) is an integer-class type if it is in a set of implementation-defined class types that behave as integer types do, as defined in below.

The range of representable values of an integer-class type is the continuous set of values over which it is defined. The values 0 and 1 are part of the range of every integer-class type. If any negative numbers are part of the range, the type is a signed-integer-class type; otherwise, it is an unsigned-integer-class type.

For every integer-class type \( I \), let \( B(1) \) be a hypothetical extended integer type of the same signedness with the smallest width (6.8.1) capable of representing the same range of values. The width of \( I \) is equal to the width of \( B(1) \).

Let \( a \) and \( b \) be objects of integer-class type \( I \), let \( x \) and \( y \) be objects of type \( B(1) \) as described above that represent the same values as \( a \) and \( b \) respectively, and let \( c \) be an lvalue of any integral type.

- For every unary operator \( @ \) for which the expression \( @x \) is well-formed, \( @a \) shall also be well-formed and have the same value, effects, and value category as \( @x \) provided that value is representable by \( I \). If \( @x \) has type bool, so too does \( @a \); if \( @x \) has type \( B(1) \), then \( @a \) has type \( I \).

- For every assignment operator \( @= \) for which \( c \) \( @= \) \( x \) is well-formed, \( c \) \( @= \) \( a \) shall also be well-formed and shall have the same value and effects as \( c \) \( @= \) \( x \). The expression \( c \) \( @= \) \( x \) shall be an lvalue referring to \( c \).

- For every binary operator \( @ \) for which \( x \) \( @ \) \( y \) is well-formed, \( a \) \( @ \) \( b \) shall also be well-formed and shall have the same value, effects, and value category as \( x \) \( @ \) \( y \) provided that value is representable by \( I \). If \( x \) \( @ \) \( y \) has type bool, so too does \( a \) \( @ \) \( b \); if \( x \) \( @ \) \( y \) has type \( B(1) \), then \( a \) \( @ \) \( b \) has type \( I \).

Expressions of integer-class type are explicitly convertible to any integral type. Expressions of integral type are both implicitly and explicitly convertible to any integer-class type. Conversions between integral and integer-class types do not exit via an exception.

An expression \( E \) of integer-class type \( I \) is contextually convertible to bool as if by bool(E != I(0)).

All integer-class types model regular (18.6) and totally_ordered (18.5.4).

A value-initialized object of integer-class type \( I \) has value 0.

For every (possibly cv-qualified) integer-class type \( I \), numeric_limits<\( I \)> is specialized such that:

- numeric_limits<\( I \)>::is_specialized is true,
- numeric_limits<\( I \)>::is_signed is true if and only if \( I \) is a signed-integer-class type,
- numeric_limits<\( I \)>::is_integer is true,
- numeric_limits<\( I \)>::is_exact is true,
- numeric_limits<\( I \)>::digits is equal to the width of the integer-class type,
- numeric_limits<\( I \)>::digits10 is equal to static_cast<int>(digits * log10(2)), and
- numeric_limits<\( I \)>::min() and numeric_limits<\( I \)>::max() return the lowest and highest representable values of \( I \), respectively, and numeric_limits<\( I \)>::lowest() returns numeric_limits<\( I \)>::min().

A type \( I \) is integer-like if it models integral<\( I \)> or if it is an integer-class type. A type \( I \) is signed-integer-like if it models signed_integral<\( I \)> or if it is a signed-integer-class type. A type \( I \) is unsigned-integer-like if it models unsigned_integral<\( I \)> or if it is an unsigned-integer-class type.

is_integer-like<\( I \)> is true if and only if \( I \) is an integer-like type. is_signed_integer-like<\( I \)> is true if and only if \( I \) is a signed-integer-like type.

Let \( i \) be an object of type \( I \). When \( i \) is in the domain of both pre- and post-increment, \( i \) is said to be incrementable. I models weakly_incrementable<\( I \)> only if

- The expressions \( ++i \) and \( i++ \) have the same domain.
- If \( i \) is incrementable, then both \( ++i \) and \( i++ \) advance \( i \) to the next element.
- If \( i \) is incrementable, then addressof(\( ++i \)) is equal to addressof(\( i \)).

[Note: For weakly_incrementable types, a equals \( b \) does not imply that \( ++a \) equals \( ++b \). (Equality does not guarantee the substitution property or referential transparency.) Algorithms on weakly incrementable types should never attempt to pass through the same incrementable value twice. They should be single-pass algorithms. These algorithms can be used with istreams as the source of the input data through the istream_iterator class template. — end note]
23.3.4.5 Concept `incrementable` [iterator.concept.inc]

The `incrementable` concept specifies requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are required to be equality-preserving, and the type is required to be `equality_comparable`. [Note: This supersedes the annotations on the increment expressions in the definition of `weakly_incrementable`. — end note]

```cpp
template<class I>
concept incrementable =
    regular<I> &&
    weakly_incrementable<I> &&
    requires(I i) {
        { i++ } -> same_as<I>;
    };
```

Let `a` and `b` be `incrementable` objects of type `I`. `I` models `incrementable` only if

1. If `bool(a == b)` then `bool(a++ == b)`.
2. If `bool(a == b)` then `bool(((void)a++, a) == ++b)`.

[Note: The requirement that `a` equals `b` implies `++a` equals `++b` (which is not true for `weakly_incrementable` types) allows the use of multi-pass one-directional algorithms with types that model `incrementable`. — end note]

23.3.4.6 Concept `input_or_output_iterator` [iterator.concept.iterator]

The `input_or_output_iterator` concept forms the basis of the iterator concept taxonomy; every iterator models `input_or_output_iterator`. This concept specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to compare iterators with sentinels (23.3.4.7), to read (23.3.4.9) or write (23.3.4.10) values, or to provide a richer set of iterator movements (23.3.4.11, 23.3.4.12, 23.3.4.13).

```cpp
template<class I>
concept input_or_output_iterator =
    requires(I i) {
        { *i } -> can-reference;
    } &&
    weakly_incrementable<I>;
```

[Note: Unlike the Cpp17Iterator requirements, the `input_or_output_iterator` concept does not require copyability. — end note]

23.3.4.7 Concept `sentinel_for` [iterator.concept.sentinel]

The `sentinel_for` concept specifies the relationship between an `input_or_output_iterator` type and a semiregular type whose values denote a range.

```cpp
template<class S, class I>
concept sentinel_for =
    semiregular<S> &&
    input_or_output_iterator<I> &&
    weakly-equality-comparable-with<S, I>;
    // See 18.5.3
```

Let `s` and `i` be values of type `S` and `I` such that `[i, s)` denotes a range. Types `S` and `I` model `sentinel_for` if

1. `i == s` is well-defined.
2. If `bool(i != s)` then `i` is dereferenceable and `[++i, s)` denotes a range.

The domain of `==` is not static. Given an iterator `i` and sentinel `s` such that `[i, s)` denotes a range and `i` != `s`, `i` and `s` are not required to continue to denote a range after incrementing any other iterator equal to `i`. Consequently, `i == s` is no longer required to be well-defined.

23.3.4.8 Concept `sized_sentinel_for` [iterator.concept.sizedsentinel]

The `sized_sentinel_for` concept specifies requirements on an `input_or_output_iterator` type `I` and a corresponding `sentinel_for` that allow the use of the `-` operator to compute the distance between them in constant time.
template<class S, class I>
concept sized_sentinel_for =
    sentinel_for<S, I> &&
    !disable_sized_sentinel_for<remove_cv_t<S>, remove_cv_t<I>> &&
    requires(const I& i, const S& s)
    { s - i } -> same_as<iter_difference_t<I>>;
    { i - s } -> same_as<iter_difference_t<I>>;
};

Let \( i \) be an iterator of type \( I \), and \( s \) a sentinel of type \( S \) such that \([i, s)\) denotes a range. Let \( N \) be the smallest number of applications of \( ++i \) necessary to make \( \text{bool}(i == s) \) be true. \( S \) and \( I \) model sized_sentinel_for only if

\[
\begin{align*}
    &- \text{If } N \text{ is representable by } \text{iter_difference_t}<I>, \text{ then } s - i \text{ is well-defined and equals } N. \\
    &- \text{If } -N \text{ is representable by } \text{iter_difference_t}<I>, \text{ then } i - s \text{ is well-defined and equals } -N.
\end{align*}
\]

2. Let \( E \) be an expression such that \( \text{decltype}(E) \) is \( T \), and let \( i \) be a dereferenceable object of type \( I \). \( I \) and \( T \) model output_iterator\(<I, T>\) only if \( *i++ = E; \) has effects equivalent to:

\*\( i = E; \)
\+
\( i; \)

[Note: Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be single-pass algorithms. — end note]
The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators of the same type may be compared and shall compare equal to other value-initialized iterators of the same type. [Note: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]

Pointers and references obtained from a forward iterator into a range [i, s) shall remain valid while [i, s) continues to denote a range.

Two dereferenceable iterators a and b of type X offer the multi-pass guarantee if:

1. \( a == b \) implies \( ++a == ++b \) and
2. the expression \((\text{void}[])(X x)(++x)(a), *a)\) is equivalent to the expression \(*a\).

[Note: The requirement that \( a == b \) implies \( ++a == ++b \) and the removal of the restrictions on the number of assignments through a mutable iterator (which applies to output iterators) allow the use of multi-pass one-directional algorithms with forward iterators. — end note]

23.3.4.12 Concept bidirectional_iterator

The bidirectional_iterator concept adds the ability to move an iterator backward as well as forward.

A bidirectional iterator \( r \) is decrementable if and only if there exists some \( q \) such that \( ++q == r \). Decrementable iterators \( r \) shall be in the domain of the expressions \(--r\) and \(r--\).

Let \( a \) and \( b \) be equal objects of type I. I models bidirectional_iterator only if:

1. If \( a \) and \( b \) are decrementable, then all of the following are true:
   1. \( \text{addressof}(-a) == \text{addressof}(a) \)
   2. \( \text{bool}(a-- == b) \)
   3. \( \text{after evaluating both} \ a-- \ \text{and} \ --b, \ \text{bool}(a == b) \) \( \text{is still true} \)
   4. \( \text{bool}(++(--a) == b) \)
2. If \( a \) and \( b \) are incrementable, then \( \text{bool}(-(-a) == b) \).

23.3.4.13 Concept random_access_iterator

The random_access_iterator concept adds support for constant-time advancement with \(+, +, -, -\), as well as the computation of distance in constant time with \(-\). Random access iterators also support array notation via subscripting.

```cpp
template<class I>
concept random_access_iterator =
    bidirectional_iterator<I> &&
    totally_ordered<I> &&
    sized_sentinel_for<I, I> &&
    requires(I i, const I j, const iter_difference_t<I> n) {
        { i + n } -> same_as<I&>;
        { j + n } -> same_as<I>;
        { n + j } -> same_as<I>;
        { i -= n } -> same_as<I&>;
        { j - n } -> same_as<I>;
    };
```
Let a and b be valid iterators of type I such that b is reachable from a after n applications of ++a, let D be iter_difference_t<I>, and let n denote a value of type D. I models random_access_iterator only if

1. (a += n) is equal to b.
2. addressof(a += n) is equal to addressof(a).
3. (a + n) is equal to (a += n).
4. For any two positive values x and y of type D, if (a + D(x + y)) is valid, then (a + D(x + y)) is equal to (a + x + y).
5. (a + D(0)) is equal to a.
6. If (a + D(n - 1)) is valid, then (a + n) is equal to [] (I c) { return ++c; } (a + D(n - 1)).
7. (b += D(-n)) is equal to a.
8. (b -= n) is equal to a.
9. addressof(b -= n) is equal to addressof(b).
10. (b - n) is equal to (b -= n).
11. If b is dereferenceable, then a[n] is valid and is equal to *b.
12. bool(a <= b) is true.

23.3.4.14 Concept contiguous_iterator \[iterator.concept.contiguous]\n
The contiguous_iterator concept provides a guarantee that the denoted elements are stored contiguously in memory.

\[
\begin{align*}
\text{template}<\text{class I}> & \\
\text{concept contiguous_iterator =} & \\
\text{random_access_iterator}\langle I \rangle & \& \\
\text{derived_from}<\text{ITER_CONCEPT}(I), \text{contiguous_iteration_tag}> & \& \\
\text{is_lvalue_reference_v<iter_reference_t<I> amorelref> } & \& \\
\text{same_as<iter_value_t<I>, remove_cvref_t<iter_reference_t<I>>> } & \& \\
\text{requires(const I& i) { } } & \rightarrow \text{same_as<add_pointer_t<iter_reference_t<I>>>} & \& \\
\end{align*}
\]

Let a and b be dereferenceable iterators and c be a non-dereferenceable iterator of type I such that b is reachable from a and c is reachable from b, and let D be iter_difference_t<I>. The type I models contiguous_iterator only if

1. to_address(a) == addressof(*a).
2. to_address(b) == to_address(a) + D(b - a), and
3. to_address(c) == to_address(a) + D(c - a).

23.3.5 C++17 iterator requirements \[iterator.cpp17]\n
In the following sections, a and b denote values of type X or const X, difference_type and reference refer to the types iterator_traits<X>::difference_type and iterator_traits<X>::reference, respectively, n denotes a value of difference_type, u, tmp, and m denote identifiers, r denotes a value of X&, t denotes a value of value type T, o denotes a value of some type that is writable to the output iterator. \[Note: For an iterator type X there must be an instantiation of iterator_traits<X> (23.3.2.3). \end{note}\n
23.3.5.1 Cpp17Iterator \[iterator.iterators]\n
The Cpp17Iterator requirements form the basis of the iterator taxonomy; every iterator meets the Cpp17Iterator requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read (23.3.5.2) or write (23.3.5.3) values, or to provide a richer set of iterator movements (23.3.5.4, 23.3.5.5, 23.3.5.6).

A type X meets the Cpp17Iterator requirements if:

1. X meets the Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17Destructible requirements (16.5.3.1) and values of type X are swappable (16.5.3.2), and
— iterator_traits<X>::difference_type is a signed integer type or void, and

— the expressions in Table 84 are valid and have the indicated semantics.

### Table 84: Cpp17Iterator requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r</td>
<td>unspecified</td>
<td></td>
<td>Preconditions: r is dereferenceable.</td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### 23.3.5.2 Input iterators

1 A class or pointer type X meets the requirements of an input iterator for the value type T if X meets the Cpp17Iterator (23.3.5.1) and Cpp17EqualityComparable (Table 25) requirements and the expressions in Table 85 are valid and have the indicated semantics.

2 In Table 85, the term the domain of == is used in the ordinary mathematical sense to denote the set of values over which == is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of == for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of == and !=. [Example: The call find(a,b,x) is defined only if the value of a has the property p defined as follows: b has property p and a value i has property p if (*i==x) or if (*i!=x and ++i has property p). — end example]

### Table 85: Cpp17InputIterator requirements (in addition to Cpp17Iterator)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>a != b</td>
<td>contextually convertible to bool</td>
<td>t(a == b)</td>
<td>Preconditions: (a, b) is in the domain of ==.</td>
</tr>
<tr>
<td>*a</td>
<td>reference, convertible to T</td>
<td></td>
<td>Preconditions: a is dereferenceable. The expression (void)*a, *a is equivalent to *a. If a == b and (a, b) is in the domain of == then *a is equivalent to *b.</td>
</tr>
<tr>
<td>a-&gt;m</td>
<td>(*a).m</td>
<td></td>
<td>Preconditions: a is dereferenceable.</td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td>Preconditions: r is dereferenceable. Postconditions: r is dereferenceable or r is past-the-end; any copies of the previous value of r are no longer required to be dereferenceable nor to be in the domain of ==.</td>
</tr>
<tr>
<td>(void)r++</td>
<td>equivalent to (void)++r</td>
<td></td>
<td></td>
</tr>
<tr>
<td>*r++</td>
<td>convertible to T</td>
<td>{ T tmp = *r; ++r; return tmp; }</td>
<td></td>
</tr>
</tbody>
</table>

3 [Note: For input iterators, a == b does not imply ++a == ++b. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on input iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Value type T is not required to be a Cpp17CopyAssignable type (Table 31).]
These algorithms can be used with istreams as the source of the input data through the `istream_iterator` class template. — end note

### 23.3.5.3 Output iterators

A class or pointer type `X` meets the requirements of an output iterator if `X` meets the `Cpp17Iterator` requirements (23.3.5.1) and the expressions in Table 86 are valid and have the indicated semantics.

#### Table 86: `Cpp17OutputIterator` requirements (in addition to `Cpp17Iterator`) [tab:outputiterator]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

2 [Note: The only valid use of an operator `*` is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be single-pass algorithms. Equality and inequality might not be defined. — end note]

### 23.3.5.4 Forward iterators

A class or pointer type `X` meets the requirements of a forward iterator if

1. `X` meets the `Cpp17InputIterator` requirements (23.3.5.2),
2. `X` meets the `Cpp17DefaultConstructible` requirements (16.5.3.1),
3. if `X` is a mutable iterator, `reference` is a reference to `T`; if `X` is a constant iterator, `reference` is a reference to `const T`,
4. the expressions in Table 87 are valid and have the indicated semantics, and
5. objects of type `X` offer the multi-pass guarantee, described below.

2 The domain of `==` for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type. [Note: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]

3 Two dereferenceable iterators `a` and `b` of type `X` offer the multi-pass guarantee if:

1. `a == b` implies `++a == ++b` and
2. `X` is a pointer type or the expression `(void)++X(a)`, `*a` is equivalent to the expression `*a`. 

§ 23.3.5.4 900
[Note: The requirement that \(a == b\) implies \(++a == ++b\) (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — end note]

Table 87: Cpp17ForwardIterator requirements (in addition to Cpp17InputIterator) [tab:forwarditerator]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>(r++)</td>
<td>convertible to (X) &amp;</td>
<td>{ (X) tmp = (r); ++(r); return tmp; }</td>
<td></td>
</tr>
<tr>
<td>*(r++)</td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5 If \(a\) and \(b\) are equal, then either \(a\) and \(b\) are both dereferenceable or else neither is dereferenceable.
6 If \(a\) and \(b\) are both dereferenceable, then \(a == b\) if and only if \(*a\) and \(*b\) are bound to the same object.

23.3.5.5 Bidirectional iterators [bidirectional.iterators]

1 A class or pointer type \(X\) meets the requirements of a bidirectional iterator if, in addition to meeting the Cpp17ForwardIterator requirements, the following expressions are valid as shown in Table 88.

Table 88: Cpp17BidirectionalIterator requirements (in addition to Cpp17ForwardIterator) [tab:bidirectionaliterator]

</table>
| \(--r\)    | \(X\) & | \(s\) such that \(r == ++s\). Preconditions: there exists \(s\) such that \(r == ++s\). Postconditions: \(r\) is dereferenceable. 
\(--(++r) == r\). 
\(--r == --s\) implies \(r == s\). 
\(\text{addressof}(r) == \text{addressof}(-r)\). | |
| \(r--\)   | convertible to \(X\) & | \{ \(X\) tmp = \(r\); \(--r\); return tmp; \} | |
| *\(r--\)  | reference | | |

2 [Note: Bidirectional iterators allow algorithms to move iterators backward as well as forward. — end note]

23.3.5.6 Random access iterators [random.access.iterators]

1 A class or pointer type \(X\) meets the requirements of a random access iterator if, in addition to meeting the Cpp17BidirectionalIterator requirements, the following expressions are valid as shown in Table 89.

Table 89: Cpp17RandomAccessIterator requirements (in addition to Cpp17BidirectionalIterator) [tab:randomaccessiterator]

### 23.3.6 Indirect callable requirements

#### 23.3.6.1 General

There are several concepts that group requirements of algorithms that take callable objects (20.14.2) as arguments.

#### 23.3.6.2 Indirect callables

The indirect callable concepts are used to constrain those algorithms that accept callable objects (20.14.2) as arguments.

```cpp
namespace std {
    template<class F, class I>
    concept indirectly_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        invocable<F, iter_value_t<I>&> &&
        invocable<F, iter_reference_t<I>> &&
        invocable<F, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F&, iter_value_t<I>&>,
            invoke_result_t<F&, iter_reference_t<I>>;}

    template<class F, class I>
    concept indirectly_regular_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        regular_invocable<F&, iter_value_t<I>&> &&
        regular_invocable<F&, iter_reference_t<I>> &&
        regular_invocable<F&, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F&, iter_value_t<I>&>,
            invoke_result_t<F&, iter_reference_t<I>>;}
```
template<class F, class I>
concept indirect_unary_predicate =
indirectly_readable<I> &&
copy_constructible<F> &&
predicate<F&, iter_value_t<I>&> &&
predicate<F&, iter_reference_t<I>><>
&&
predicate<F&, iter_common_reference_t<I>><>;

template<class F, class I1, class I2>
concept indirect_binary_predicate =
indirectly_readable<I1> && indirectly_readable<I2> &&
copy_constructible<F> &&
predicate<F&, iter_value_t<I1>&, iter_value_t<I2>&> &&
predicate<F&, iter_value_t<I1>&, iter_reference_t<I2>> &&
predicate<F&, iter_reference_t<I1>, iter_value_t<I2>&> &&
predicate<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
predicate<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

template<class F, class I1, class I2 = I1>
concept indirect_equivalence_relation =
indirectly_readable<I1> && indirectly_readable<I2> &&
copy_constructible<F> &&
equivalence_relation<F&, iter_value_t<I1>&, iter_value_t<I2>&> &&
equivalence_relation<F&, iter_value_t<I1>&, iter_reference_t<I2>> &&
equivalence_relation<F&, iter_reference_t<I1>, iter_value_t<I2>&> &&
equivalence_relation<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
equivalence_relation<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

template<class F, class I1, class I2 = I1>
concept indirect_strict_weak_order =
indirectly_readable<I1> && indirectly_readable<I2> &&
copy_constructible<F> &&
strict_weak_order<F&, iter_value_t<I1>&, iter_value_t<I2>&> &&
strict_weak_order<F&, iter_value_t<I1>&, iter_reference_t<I2>> &&
strict_weak_order<F&, iter_reference_t<I1>, iter_value_t<I2>&> &&
strict_weak_order<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
strict_weak_order<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

23.3.6.3 Class template projected [projected]
1 Class template projected is used to constrain algorithms that accept callable objects and projections (16.3.22). It combines a indirectly_readable type I and a callable object type Proj into a new indirectly_readable type whose reference type is the result of applying Proj to the iter_reference_t of I.

namespace std {
    template<indirectly_readable I, indirectly_regular_unary_invocable<I> Proj>
    struct projected {
        using value_type = remove_cvref_t<indirect_result_t<Proj&, I>>;
        indirect_result_t<Proj&, I> operator*() const; // not defined
    };

    template<weakly_incrementable I, class Proj>
    struct incrementable_traits<projected<I, Proj>> {
        using difference_type = iter_difference_t<I>;
    };
}

23.3.7 Common algorithm requirements [alg.req]
23.3.7.1 General [alg.req.general]
1 There are several additional iterator concepts that are commonly applied to families of algorithms. These group together iterator requirements of algorithm families. There are three relational concepts that specify how element values are transferred between indirectly_readable and indirectly_writable types: indirectly_movable, indirectly_copyable, and indirectly_swappable. There are three relational concepts for rearrangements:
permutable, mergeable, and sortable. There is one relational concept for comparing values from different sequences: indirectly_comparable.

2 [Note: The ranges::less function object type used in the concepts below imposes constraints on the concepts’ arguments in addition to those that appear in the concepts’ bodies (20.14.8). — end note]

23.3.7.2 Concept indirectly_movable

1 The indirectly_movable concept specifies the relationship between a indirectly_readable type and a indirectly_writable type between which values may be moved.

```cpp
template<class In, class Out>
concept indirectly_movable =
  indirectly_readable<In> &&
  indirectly_writable<Out, iter_rvalue_reference_t<In>>;
```

2 The indirectly_movable_storable concept augments indirectly_movable with additional requirements enabling the transfer to be performed through an intermediate object of the indirectly_readable type’s value type.

```cpp
template<class In, class Out>
concept indirectly_movable_storable =
  indirectly_movable<In, Out> &&
  indirectly_writable<Out, iter_value_t<In>> &&
  movable<iter_value_t<In>> &&
  constructible_from<iter_value_t<In>, iter_rvalue_reference_t<In>> &&
  assignable_from<iter_value_t<In>&, iter_rvalue_reference_t<In>>;
```

3 Let i be a dereferenceable value of type In. In and Out model indirectly_movable_storable<In, Out> only if after the initialization of the object obj in

```cpp
iter_value_t<In> obj(ranges::iter_move(i));
```

obj is equal to the value previously denoted by *i. If iter_rvalue_reference_t<In> is an rvalue reference type, the resulting state of the value denoted by *i is valid but unspecified (16.5.5.16).

23.3.7.3 Concept indirectly_copyable

1 The indirectly_copyable concept specifies the relationship between a indirectly_readable type and a indirectly_writable type between which values may be copied.

```cpp
template<class In, class Out>
concept indirectly_copyable =
  indirectly_readable<In> &&
  indirectly_writable<Out, iter_reference_t<In>>;
```

2 The indirectly_copyable_storable concept augments indirectly_copyable with additional requirements enabling the transfer to be performed through an intermediate object of the indirectly_readable type’s value type. It also requires the capability to make copies of values.

```cpp
template<class In, class Out>
concept indirectly_copyable_storable =
  indirectly_copyable<In, Out> &&
  indirectly_writable<Out, iter_value_t<In>> &&
  movable<iter_value_t<In>> &&
  constructible_from<iter_value_t<In>, iter_rvalue_reference_t<In>> &&
  assignable_from<iter_value_t<In>&, iter_rvalue_reference_t<In>>;
```

3 Let i be a dereferenceable value of type In. In and Out model indirectly_copyable_storable<In, Out> only if after the initialization of the object obj in

```cpp
iter_value_t<In> obj(*i);
```

obj is equal to the value previously denoted by *i. If iter_reference_t<In> is an rvalue reference type, the resulting state of the value denoted by *i is valid but unspecified (16.5.5.16).
23.3.7.4 Concept indirectly_swappable

The indirectly_swappable concept specifies a swappable relationship between the values referenced by two indirectly_readable types.

```cpp
template<class I1, class I2 = I1>
concept indirectly_swappable =
    indirectly_readable<I1> && indirectly_readable<I2> &&
    requires(const I1 i1, const I2 i2) {
        ranges::iter_swap(i1, i1);
        ranges::iter_swap(i2, i2);
        ranges::iter_swap(i1, i2);
        ranges::iter_swap(i2, i1);
    };
```

23.3.7.5 Concept indirectly_comparable

The indirectly_comparable concept specifies the common requirements of algorithms that compare values from two different sequences.

```cpp
template<class I1, class I2, class R, class P1 = identity, class P2 = identity>
concept indirectly_comparable =
    indirect_binary_predicate<R, projected<I1, P1>, projected<I2, P2>>;
```

23.3.7.6 Concept permutable

The permutable concept specifies the common requirements of algorithms that reorder elements in place by moving or swapping them.

```cpp
template<class I>
concept permutable =
    forward_iterator<I> &&
    indirectly_movable_storable<I, I> &&
    indirectly_swappable<I, I>;
```

23.3.7.7 Concept mergeable

The mergeable concept specifies the requirements of algorithms that merge sorted sequences into an output sequence by copying elements.

```cpp
template<class I1, class I2, class Out, class R = ranges::less, class P1 = identity, class P2 = identity>
concept mergeable =
    input_iterator<I1> &&
    input_iterator<I2> &&
    weakly_incrementable<Out> &&
    indirectly_copyable<I1, Out> &&
    indirectly_copyable<I2, Out> &&
    indirect_strict_weak_order<R, projected<I1, P1>, projected<I2, P2>>;
```

23.3.7.8 Concept sortable

The sortable concept specifies the common requirements of algorithms that permute sequences into ordered sequences (e.g., sort).

```cpp
template<class I, class R = ranges::less, class P = identity>
concept sortable =
    permutable<I> &&
    indirect_strict_weak_order<R, projected<I, P>>;
```

23.4 Iterator primitives

To simplify the use of iterators, the library provides several classes and functions.

23.4.1 Standard iterator tags

It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces category tag classes which are used as compile time tags for algorithm selection. They are: output_iterator_tag, input_iterator_tag, forward_iterator_tag, bidirectional_iterator_tag.
random_access_iterator_tag, and contiguous_iterator_tag. For every iterator of type \( I \), \( \text{iterator_traits}<I>::\text{iterator_category} \) shall be defined to be a category tag that describes the iterator’s behavior. Additionally, \( \text{iterator_traits}<I>::\text{iterator_concept} \) may be used to indicate conformance to the iterator concepts (23.3.4).

```cpp
namespace std {
    struct output_iterator_tag { };
    struct input_iterator_tag { };
    struct forward_iterator_tag: public input_iterator_tag { };
    struct bidirectional_iterator_tag: public forward_iterator_tag { };
    struct random_access_iterator_tag: public bidirectional_iterator_tag { };
    struct contiguous_iterator_tag: public random_access_iterator_tag { };
}
```

[Example: For a program-defined iterator BinaryTreeIterator, it could be included into the bidirectional iterator category by specializing the iterator_traits template:

```cpp
template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
    using iterator_category = bidirectional_iterator_tag;
    using difference_type = ptrdiff_t;
    using value_type = T;
    using pointer = T*;
    using reference = T&;
};
```

— end example]

[Example: If evolve() is well-defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:

```cpp
template<class BidirectionalIterator>
inline void
evolve(BidirectionalIterator first, BidirectionalIterator last) {
    evolve(first, last,
        typename iterator_traits<BidirectionalIterator>::iterator_category());
}

template<class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
    bidirectional_iterator_tag) {
    // more generic, but less efficient algorithm
}

template<class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
    random_access_iterator_tag) {
    // more efficient, but less generic algorithm
}
```

— end example]

### 23.4.2 Iterator operations [iterator.operations]

Since only random access iterators provide + and - operators, the library provides two function templates advance and distance. These function templates use + and - for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

```cpp
template<class InputIterator, class Distance>
constexpr void advance(InputIterator& i, Distance n);
```

**Preconditions:** \( n \) is negative only for bidirectional iterators.

**Effects:** Increments \( i \) by \( n \) if \( n \) is non-negative, and decrements \( i \) by \(-n\) otherwise.

```cpp
template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::difference_type
distance(InputIterator first, InputIterator last);
```

**Preconditions:** last is reachable from first, or InputIterator meets the Cpp17RandomAccessIterator requirements and first is reachable from last.
Effects: If InputIterator meets the Cpp17RandomAccessIterator requirements, returns (last - first); otherwise, returns the number of increments needed to get from first to last.

template<class InputIterator>
constexpr InputIterator next(InputIterator x, typename iterator_traits<InputIterator>::difference_type n = 1);

Effects: Equivalent to: advance(x, n); return x;

template<class BidirectionalIterator>
constexpr BidirectionalIterator prev(BidirectionalIterator x, typename iterator_traits<BidirectionalIterator>::difference_type n = 1);

Effects: Equivalent to: advance(x, -n); return x;

23.4.3 Range iterator operations [range.iter.ops]
The library includes the function templates ranges::advance, ranges::distance, ranges::next, and ranges::prev to manipulate iterators. These operations adapt to the set of operators provided by each iterator category to provide the most efficient implementation possible for a concrete iterator type. [Example: ranges::advance uses the + operator to move a random_access_iterator forward n steps in constant time. For an iterator type that does not model random_access_iterator, ranges::advance instead performs n individual increments with the ++ operator. — end example]
The function templates defined in this subclause are not found by argument-dependent name lookup (6.5.2). When found by unqualified (6.5.1) name lookup for the postfix-expression in a function call (7.6.1.2), they inhibit argument-dependent name lookup.

[Example:
  void foo() {
    using namespace std::ranges;
    std::vector<int> vec{1,2,3};
    distance(begin(vec), end(vec));  // #1
  }
]
The function call expression at #1 invokes std::ranges::distance, not std::distance, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::distance is more specialized (13.7.6.2) than std::ranges::distance since the former requires its first two parameters to have the same type. — end example]
The number and order of deducible template parameters for the function templates defined in this subclause is unspecified, except where explicitly stated otherwise.

23.4.3.1 ranges::advance [range.iter.op.advance]
template<input_or_output_iterator I>
constexpr void ranges::advance(I& i, iter_difference_t<I> n);

Preconditions: If I does not model bidirectional_iterator, n is not negative.

Effects:
(2.1)  If I models random_access_iterator, equivalent to i += n.
(2.2)  Otherwise, if n is non-negative, increments i by n.
(2.3)  Otherwise, decrements i by -n.

template<input_or_output_iterator I, sentinel_for<I> S>
constexpr void ranges::advance(I& i, S bound);

Preconditions: [i, bound) denotes a range.

Effects:
(4.1)  If I and S model assignable_from<I&, S>, equivalent to i = std::move(bound).
(4.2)  Otherwise, if S and I model sized_sentinel_for<S, I>, equivalent to ranges::advance(i, bound - i).
(4.3)  Otherwise, while bool(i != bound) is true, increments i.
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr iter_difference_t<I> ranges::advance(I& i, iter_difference_t<I> n, S bound);

Preconditions: If \( n > 0 \), \([i, \text{ bound})\) denotes a range. If \( n = 0 \), \([i, \text{ bound})\) or \((\text{ bound}, i)\) denotes a range. If \( n < 0 \), \((\text{ bound}, i)\) denotes a range, \( I \) models bidirectional_iterator, and \( I \) and \( S \) model same_as\(<I, S>\).

Effects:

- If \( S \) and \( I \) model sized_sentinel_for\(<S, I>\):
  - If \(|n| \geq |\text{ bound} - i|\), equivalent to ranges::advance\((i, \text{ bound})\).
  - Otherwise, equivalent to ranges::advance\((i, n)\).

- Otherwise,

  - If \( n \) is non-negative, while bool\((i != \text{ bound})\) is true, increments \( i \) but at most \( n \) times.
  
  - Otherwise, while bool\((i != \text{ bound})\) is true, decrements \( i \) but at most -\( n \) times.

Returns: \( n - M \), where \( M \) is the difference between the ending and starting positions of \( i \).

23.4.3.2 ranges::distance

```cpp
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr iter_difference_t<I> ranges::distance(I first, S last);
```

Preconditions: \([\text{ first}, \text{ last})\) denotes a range, or \([\text{ last}, \text{ first})\) denotes a range and \( S \) and \( I \) model same_as\(<S, I>\) && sized_sentinel_for\(<S, I>\).

Effects: If \( S \) and \( I \) model sized_sentinel_for\(<S, I>\), returns \((\text{ last} - \text{ first})\); otherwise, returns the number of increments needed to get from \( \text{ first} \) to \( \text{ last} \).

```cpp
template<range R>
constexpr range_difference_t<R> ranges::distance(R&& r);
```

Effects: If \( R \) models sized_range, equivalent to:

```cpp
return static_cast<range_difference_t<R>>(ranges::size(r)); // 24.3.9
```

Otherwise, equivalent to:

```cpp
return ranges::distance(ranges::begin(r), ranges::end(r)); // 24.3
```

23.4.3.3 ranges::next

```cpp
template<input_or_output_iterator I>
constexpr I ranges::next(I x);
```

Effects: Equivalent to: \(+x\); return \( x \);

```cpp
template<input_or_output_iterator I>
constexpr I ranges::next(I x, iter_difference_t<I> n);
```

Effects: Equivalent to: ranges::advance\((x, n)\); return \( x \);

```cpp
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr I ranges::next(I x, S bound);
```

Effects: Equivalent to: ranges::advance\((x, \text{ bound})\); return \( x \);

```cpp
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr I ranges::next(I x, iter_difference_t<I> n, S bound);
```

Effects: Equivalent to: ranges::advance\((x, n, \text{ bound})\); return \( x \);

23.4.3.4 ranges::prev

```cpp
template<bidirectional_iterator I>
constexpr I ranges::prev(I x);
```

Effects: Equivalent to: \(-x\); return \( x \);

§ 23.4.3.4
23.5 Iterator adaptors [predef.iterators]

23.5.1 Reverse iterators [reverse.iterators]

1 Class template `reverse_iterator` is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence.

23.5.1.1 Class template `reverse_iterator` [reverse.iterator]

```cpp
namespace std {
    template<class Iterator>
    class reverse_iterator {
public:
        using iterator_type = Iterator;
        using iterator_concept = see below;
        using iterator_category = see below;
        using value_type = iter_value_t<Iterator>;
        using difference_type = iter_difference_t<Iterator>;
        using pointer = typename iterator_traits<Iterator>::pointer;
        using reference = iter_reference_t<Iterator>;

        constexpr reverse_iterator();
        constexpr explicit reverse_iterator(Iterator x);
        template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
        template<class U> constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);
        constexpr Iterator base() const;
        constexpr reference operator*() const;
        constexpr pointer operator->() const requires see below;
        constexpr reverse_iterator& operator++();
        constexpr reverse_iterator operator++(int);
        constexpr reverse_iterator& operator--();
        constexpr reverse_iterator operator--(int);
        constexpr reverse_iterator operator+ (difference_type n) const;
        constexpr reverse_iterator& operator+=(difference_type n);
        constexpr reverse_iterator operator- (difference_type n) const;
        constexpr reverse_iterator& operator-=(difference_type n);
        template<indirectly_swappable<Iterator> Iterator2>
        friend constexpr void iter_swap(const reverse_iterator& x,
                                         const reverse_iterator<Iterator2>& y) noexcept(see below);

        friend constexpr iter_rvalue_reference_t<Iterator>
        iter_move(const reverse_iterator& i) noexcept(see below);
        template<indirectly_swappable<Iterator> Iterator2>
        friend constexpr void
        iter_swap(const reverse_iterator& x,
                  const reverse_iterator<Iterator2>& y) noexcept(see below);

    protected:
        Iterator current;
    };
}
```

1 The member `typedef-name iterator_concept` denotes

(1.1) — `random_access_iterator_tag` if `Iterator` models `random_access_iterator`, and

(1.2) — `bidirectional_iterator_tag` otherwise.
The member *typedef-name* `iterator_category` denotes

(2.1) — `random_access_iterator_tag` if the type `iterator_traits<Iterator>::iterator_category` models `derived_from<random_access_iterator_tag>`, and

(2.2) — `iterator_traits<Iterator>::iterator_category` otherwise.

### 23.5.1.2 Requirements

The template parameter `Iterator` shall either meet the requirements of a `Cpp17BidirectionalIterator` (23.3.5.5) or model `bidirectional_iterator` (23.3.4.12).

Additionally, `Iterator` shall either meet the requirements of a `Cpp17RandomAccessIterator` (23.3.5.6) or model `random_access_iterator` (23.3.4.13) if the definitions of any of the members

(2.1) — `operator+`, `operator-`, `operator+=`, `operator-=`, `operator[]` (23.5.1.5),

or the non-member operators (23.5.1.7)

(2.2) — `operator<`, `operator>`, `operator<=`, `operator>=`, `operator-`, or `operator+` (23.5.1.8)

are instantiated (13.9.1).

### 23.5.1.3 Construction and assignment

```cpp
constexpr reverse_iterator();
```

**Effects:** Value-initializes `current`. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```cpp
constexpr explicit reverse_iterator(Iterator x);
```

**Effects:** Initializes `current` with `x`.

```cpp
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
```

**Effects:** Initializes `current` with `u.current`.

```cpp
template<class U>
constexpr reverse_iterator&
operator=(const reverse_iterator<U>& u);
```

**Effects:** Assigns `u.base()` to `current`.

**Returns:** `*this`.

### 23.5.1.4 Conversion

```cpp
constexpr Iterator base() const; // explicit
```

**Returns:** `current`.

### 23.5.1.5 Element access

```cpp
constexpr reference operator*() const;
```

**Effects:** As if by:

```cpp
Iterator tmp = current;
return *--tmp;
```

```cpp
constexpr pointer operator->() const
requires (is_pointer_v<Iterator> ||
 requires (const Iterator i) { i.operator->(); });
```

**Effects:**

(2.1) — If `Iterator` is a pointer type, equivalent to: `return prev(current);`

(2.2) — Otherwise, equivalent to: `return prev(current).operator->();`

```cpp
constexpr unspecified operator[](difference_type n) const;
```

**Returns:** `current[-n-1]`.

§ 23.5.1.5 910
23.5.1.6 Navigation

```cpp
constexpr reverse_iterator operator+(difference_type n) const;

Returns: reverse_iterator(current-n).
```

```cpp
constexpr reverse_iterator operator-(difference_type n) const;

Returns: reverse_iterator(current+n).
```

```cpp
constexpr reverse_iterator& operator++();

Effects: As if by: --current;

Returns: *this.
```

```cpp
constexpr reverse_iterator operator++(int);

Effects: As if by:
    reverse_iterator tmp = *this;
    --current;
    return tmp;
```

```cpp
constexpr reverse_iterator& operator--();

Effects: As if by ++current.

Returns: *this.
```

```cpp
constexpr reverse_iterator operator--(int);

Effects: As if by:
    reverse_iterator tmp = *this;
    ++current;
    return tmp;
```

```cpp
constexpr reverse_iterator& operator+=(difference_type n);

Effects: As if by:
    current -= n;

Returns: *this.
```

```cpp
constexpr reverse_iterator& operator-=(difference_type n);

Effects: As if by:
    current += n;

Returns: *this.
```

23.5.1.7 Comparisons

```cpp
template<class Iterator1, class Iterator2>
constexpr bool operator==(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() == y.base() is well-formed and convertible to bool.

Returns: x.base() == y.base().
```

```cpp
template<class Iterator1, class Iterator2>
constexpr bool operator!=(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() != y.base() is well-formed and convertible to bool.

Returns: x.base() != y.base().
```

```cpp
template<class Iterator1, class Iterator2>
constexpr bool operator<(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() > y.base() is well-formed and convertible to bool.
```

§ 23.5.1.7 911
template<class Iterator1, class Iterator2>
constexpr bool operator>(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.
Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Constraints: x.base() <= y.base() is well-formed and convertible to bool.
Returns: x.base() <= y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator>=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Constraints: x.base() >= y.base() is well-formed and convertible to bool.
Returns: x.base() >= y.base().

template<class Iterator1, three_way_comparable_with<Iterator1> Iterator2>
constexpr compare_three_way_result_t<Iterator1, Iterator2>
operator<=>(const reverse_iterator<Iterator1>& x,
             const reverse_iterator<Iterator2>& y);

Returns: y.base() <=> x.base().

Note: The argument order in the Returns: element is reversed because this is a reverse iterator. — end note

23.5.1.8 Non-member functions

template<class Iterator1, class Iterator2>
constexpr auto operator-(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());

Returns: y.base() - x.base().

template<class Iterator>
constexpr reverse_iterator<Iterator> operator+(
    iter_difference_t<Iterator> n,
    const reverse_iterator<Iterator>& x);

Returns: reverse_iterator<Iterator>(x.base() - n).

friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const reverse_iterator& i) noexcept(see below);

Effects: Equivalent to:
    auto tmp = i.base();
    return ranges::iter_move(--tmp);

Remarks: The expression in noexcept is equivalent to:
    is_nothrow_copy_constructible_v<Iterator> &&
    noexcept(ranges::iter_move(--declval<Iterator&>()));

template<indirectly_swappable<Iterator> Iterator2>
friend constexpr void
iter_swap(const reverse_iterator& x,
          const reverse_iterator<Iterator2>& y) noexcept(see below);

Effects: Equivalent to:
auto xtmp = x.base();
auto ytmp = y.base();
ranges::iter_swap(--xtmp, --ytmp);

Remarks: The expression in noexcept is equivalent to:

```cpp
is_nothrow_copy_constructible_v<Iterator> &&
is_nothrow_copy_constructible_v<Iterator2> &&
noexcept(ranges::iter_swap(--declval<Iterator&>(), --declval<Iterator2&>()))
```

```cpp
template<class Iterator>
constexpr reverse_iterator<Iterator> make_reverse_iterator(Iterator i);
```

Returns: `reverse_iterator<Iterator>(i)`.

23.5.2 Insert iterators

To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called insert iterators, are provided in the library. With regular iterator classes,

```cpp
while (first != last) *result++ = *first++;
```

causes a range `[first, last)` to be copied into a range starting with result. The same code with result being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the insert mode instead of the regular overwrite mode.

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators meet the requirements of output iterators. `operator*` returns the insert iterator itself. The assignment `operator=(const T& x)` is defined on insert iterators to allow writing into them, it inserts x right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. `back_insert_iterator` inserts elements at the end of a container, `front_insert_iterator` inserts elements at the beginning of a container, and `insert_iterator` inserts elements where the iterator points to in a container. `back_inserter`, `front_inserter`, and `inserter` are three functions making the insert iterators out of a container.

### 23.5.2.1 Class template back_insert_iterator

```cpp
namespace std {
    template<class Container>
    class back_insert_iterator {
        protected:
            Container* container = nullptr;

        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = ptrdiff_t;
            using pointer = void;
            using reference = void;
            using container_type = Container;

            constexpr back_insert_iterator() noexcept = default;
            constexpr explicit back_insert_iterator(Container& x);
            constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
            constexpr back_insert_iterator& operator=(typename Container::value_type&& value);

            constexpr back_insert_iterator& operator*();
            constexpr back_insert_iterator& operator++();
            constexpr back_insert_iterator operator++(int);
    }
}
```

### 23.5.2.1.1 Operations

```cpp
constexpr explicit back_insert_iterator(Container& x);
```

Effects: Initializes container with addressof(x).
constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
  
    Effects: As if by: container->push_back(value);
    
    Returns: *this.

constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
  
    Effects: As if by: container->push_back(std::move(value));
    
    Returns: *this.

castexpr back_insert_iterator& operator*();
    
    Returns: *this.

castexpr back_insert_iterator& operator++();
castexpr back_insert_iterator& operator++(int);
    
    Returns: *this.

23.5.2.1.2  back_inserter

    template<class Container>
        constexpr back_insert_iterator<Container> back_inserter(Container& x);
                                  
    Returns: back_insert_iterator<Container>(x).

23.5.2.2  Class template front_insert_iterator

namespace std {
   template<class Container>
       class front_insert_iterator {
         protected:
           Container* container = nullptr;

         public:
           using iterator_category = output_iterator_tag;
           using value_type = void;
           using difference_type = ptrdiff_t;
           using pointer = void;
           using reference = void;
           using container_type = Container;

           constexpr front_insert_iterator() noexcept = default;
           constexpr explicit front_insert_iterator(Container& x);
           constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
           constexpr front_insert_iterator& operator=(typename Container::value_type&& value);

           constexpr front_insert_iterator& operator*();
           constexpr front_insert_iterator& operator++();
           constexpr front_insert_iterator& operator++(int);
       };
}

23.5.2.2.1  Operations

constexpr explicit front_insert_iterator(Container& x);
  
    Effects: Initializes container with addressof(x).

constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
  
    Effects: As if by: container->push_front(value);
    
    Returns: *this.

constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
  
    Effects: As if by: container->push_front(std::move(value));
    
    Returns: *this.
constexpr front_insert_iterator& operator*();

Returns: *this.

constexpr front_insert_iterator& operator++();
constexpr front_insert_iterator operator++(int);

Returns: *this.

23.5.2.2 front_inserter

template<class Container>
constexpr front_insert_iterator<Container> front_inserter(Container& x);

Returns: front_insert_iterator<Container>(x).

23.5.2.3 Class template insert_iterator

namespace std {
    template<class Container>
    class insert_iterator {
    protected:
        Container* container = nullptr;
        ranges::iterator_t<Container> iter = ranges::iterator_t<Container>();

    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = ptrdiff_t;
        using pointer = void;
        using reference = void;
        using container_type = Container;

        insert_iterator() = default;
        constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
        constexpr insert_iterator& operator=(const typename Container::value_type& value);
        constexpr insert_iterator& operator=(typename Container::value_type&& value);
        constexpr insert_iterator& operator*();
        constexpr insert_iterator& operator++();
        constexpr insert_iterator& operator++(int);
    };
}

23.5.2.3.1 Operations

constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);

Effects: Initializes container with addressof(x) and iter with i.

constexpr insert_iterator& operator=(const typename Container::value_type& value);

Effects: As if by:
    iter = container->insert(iter, value);
    ++iter;

Returns: *this.

constexpr insert_iterator& operator=(typename Container::value_type&& value);

Effects: As if by:
    iter = container->insert(iter, std::move(value));
    ++iter;

Returns: *this.

constexpr insert_iterator& operator*();

Returns: *this.
constexpr insert_iterator& operator++();
constexpr insert_iterator& operator++(int);

Returns: *this.

23.5.2.3.2 inserter [inserter]

template<class Container>
constexpr insert_iterator<Container>
inserter(Container& x, ranges::iterator_t<Container> i);

Returns: insert_iterator<Container>(x, i).

23.5.3 Move iterators and sentinels [move.iterators]

Class template move_iterator is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator’s indirection operator to an rvalue. Some generic algorithms can be called with move iterators to replace copying with moving.

[Example:

```cpp
list<string> s;
// populate the list
vector<string> v1(s.begin(), s.end()); // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()), make_move_iterator(s.end())); // moves strings into v2
```

— end example]

23.5.3.1 Class template move_iterator [move.iterator]

namespace std {

    template<class Iterator>
    class move_iterator {
    public:
        using iterator_type = Iterator;
        using iterator_concept = input_iterator_tag;
        using iterator_category = see below;
        using value_type = iter_value_t<Iterator>;
        using difference_type = iter_difference_t<Iterator>;
        using pointer = Iterator;
        using reference = iter_rvalue_reference_t<Iterator>;

        constexpr move_iterator();
        explicit move_iterator(Iterator i);
        template<class U> constexpr move_iterator(const move_iterator<U>& u);
        template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

        constexpr iterator_type base() const &;
        constexpr iterator_type base() &&;
        constexpr reference operator*() const;
        constexpr move_iterator& operator++();
        constexpr auto operator++(int);
        constexpr move_iterator& operator--();
        constexpr move_iterator operator--(int);

        constexpr move_iterator operator+(difference_type n) const;
        constexpr move_iterator& operator+=(difference_type n);
        constexpr move_iterator operator-(difference_type n) const;
        constexpr move_iterator& operator-=(difference_type n);

        template<sentinel_for<Iterator> S>
        friend constexpr bool operator==(const move_iterator& x, const move_sentinel<S>& y);

    };

}
template<sized_sentinel_for<Iterator> S>
friend constexpr iter_difference_t<Iterator>
operator-(const move_sentinel<S>& x, const move_iterator& y);

friend constexpr iter_difference_t<Iterator>
operator-(const move_iterator& x, const move_sentinel<S>& y);
friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const move_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)));

private:
  Iterator current; // exposition only
};

The member typedef-name iterator_category denotes
— random_access_iterator_tag if the type iterator_traits<Iterator>::iterator_category models
derived_from<random_access_iterator_tag>, and
— iterator_traits<Iterator>::iterator_category otherwise.

23.5.3.2 Requirements

The template parameter Iterator shall either meet the Cpp17InputIterator requirements (23.3.5.2) or model input_iterator (23.3.4.9). Additionally, if any of the bidirectional traversal functions are instantiated, the template parameter shall either meet the Cpp17BidirectionalIterator requirements (23.3.5.5) or model bidirectional_iterator (23.3.4.12). If any of the random access traversal functions are instantiated, the template parameter shall either meet the Cpp17RandomAccessIterator requirements (23.3.5.6) or model random_access_iterator (23.3.4.13).

23.5.3.3 Construction and assignment

constexpr move_iterator();

Effects: Constructs a move_iterator, value-initializing current. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type Iterator.

customexpr explicit move_iterator(Iterator i);

Effects: Constructs a move_iterator, initializing current with std::move(i).

template<class U> constexpr move_iterator(const move_iterator<U>& u);

Mandates: U is convertible to Iterator.

Effects: Constructs a move_iterator, initializing current with u.base().

template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

Mandates: U is convertible to Iterator.

Effects: Assigns u.base() to current.

23.5.3.4 Conversion

constexpr Iterator base() const &;

Constraints: Iterator satisfies copy_constructible.

Preconditions: Iterator models copy_constructible.

Returns: current.

customexpr Iterator base() &&;

Returns: std::move(current).
23.5.3.5  Element access

constexpr reference operator*() const;

   Effects: Equivalent to: return ranges::iter_move(current);

constexpr reference operator[](difference_type n) const;

   Effects: Equivalent to: ranges::iter_move(current + n);

23.5.3.6  Navigation

constexpr move_iterator& operator++();

   Effects: As if by ++current.

   Returns: *this.

constexpr auto operator++(int);

   Effects: If Iterator models forward_iterator, equivalent to:
   move_iterator tmp = *this;
   ++current;
   return tmp;
   Otherwise, equivalent to ++current.

constexpr move_iterator& operator--();

   Effects: As if by --current.

   Returns: *this.

constexpr move_iterator operator--(int);

   Effects: As if by:
   move_iterator tmp = *this;
   --current;
   return tmp;

constexpr move_iterator operator+(difference_type n) const;

   Returns: move_iterator(current + n).

constexpr move_iterator& operator+=(difference_type n);

   Effects: As if by:
   current += n;

   Returns: *this.

constexpr move_iterator operator-(difference_type n) const;

   Returns: move_iterator(current - n).

constexpr move_iterator& operator-=(difference_type n);

   Effects: As if by: current -= n;

   Returns: *this.

23.5.3.7  Comparisons

template<class Iterator1, class Iterator2>
   constexpr bool operator==(const move_iterator<Iterator1>& x,
                            const move_iterator<Iterator2>& y);

template<sentinel_for<Iterator> S>
   friend constexpr bool operator==(const move_iterator& x,
                                   const move_sentinel<S>& y);

   Constraints: x.base() == y.base() is well-formed and convertible to bool.

   Returns: x.base() == y.base.
template<class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.
Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.
Returns: !(y < x).

template<class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.
Returns: y < x.

23.5.3.8 Non-member functions

 template<indirectly_swappable<Iterator> Iterator2>
friend constexpr void
iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y);

Effects: Equivalent to: ranges::iter_swap(x.current, y.current).
template<class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);

6 Returns: move_iterator<Iterator>(std::move(i)).

23.5.3.9 Class template move_sentinel

Class template move_sentinel is a sentinel adaptor useful for denoting ranges together with move_iterator. When an input iterator type I and sentinel type S model sentinel_for<S, I>, move_sentinel<S> and move_iterator<I> model sentinel_for<move_sentinel<S>, move_iterator<I>> as well.

[Example: A move_if algorithm is easily implemented with copy_if using move_iterator and move_sentinel:

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, indirect_unary_predicate<I> Pred>
requires indirectly_movable<I, O>
void move_if(I first, S last, O out, Pred pred) {
  std::ranges::copy_if(move_iterator<I>{first}, move_sentinel<S>{last}, out, pred);
}
— end example]

namespace std {
  template<semiregular S>
  class move_sentinel {
    public:
      constexpr move_sentinel();
      constexpr explicit move_sentinel(S s);
      template<class S2>
      requires convertible_to<const S2&, S>
      constexpr move_sentinel(const move_sentinel<S2>& s);
      template<class S2>
      requires assignable_from<S&, const S2&>
      constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

      constexpr S base() const;
    private:
      S last;  // exposition only
    }
  }

23.5.3.10 Operations

constexpr move_sentinel();

1 Effects: Value-initializes last. If is_trivially_default_constructible_v<S> is true, then this constructor is a constexpr constructor.

constexpr explicit move_sentinel(S s);

2 Effects: Initializes last with std::move(s).

template<class S2>
requires convertible_to<const S2&, S>
constexpr move_sentinel(const move_sentinel<S2>& s);

3 Effects: Initializes last with s.last.

template<class S2>
requires assignable_from<S&, const S2&>
constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

4 Effects: Equivalent to: last = s.last; return *this;

constexpr S base() const;

5 Returns: last.
23.5.4 Common iterators

23.5.4.1 Class template common_iterator

Class template common_iterator is an iterator/sentinel adaptor that is capable of representing a non-common range of elements (where the types of the iterator and sentinel differ) as a common range (where they are the same). It does this by holding either an iterator or a sentinel, and implementing the equality comparison operators appropriately.

[Note: The common_iterator type is useful for interfacing with legacy code that expects the begin and end of a range to have the same type. — end note]

[Example:

template<class ForwardIterator>
void fun(ForwardIterator begin, ForwardIterator end);

list<int> s;
// populate the list s
using CI = common_iterator<counted_iterator<list<int>::iterator>, default_sentinel_t>;
// call fun on a range of 10 ints
fun(CI(counted_iterator(s.begin(), 10)), CI(default_sentinel));
— end example]

namespace std {
    template<input_or_output_iterator I, sentinel_for<I> S>
    requires (!same_as<I, S> && copyable<I>)
    class common_iterator {
        public:
            constexpr common_iterator() = default;
            constexpr common_iterator(I i);
            constexpr common_iterator(S s);
            template<class I2, class S2>
            requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
            constexpr common_iterator(const common_iterator<I2, S2>& x);
            template<class I2, class S2>
            requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
            assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
            common_iterator& operator=(const common_iterator<I2, S2>& x);

            decltype(auto) operator*();
            decltype(auto) operator*() const
                requires dereferenceable<const I>;
            decltype(auto) operator->() const
                requires see below;

            common_iterator& operator++();
            decltype(auto) operator++(int);
            template<class I2, sentinel_for<I> S2>
            requires sentinel_for<S, I2>
            friend bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
            template<class I2, sentinel_for<I> S2>
            requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
            friend bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
            template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
            requires sized_sentinel_for<S, I2>
            friend iter_difference_t<I2> operator-(
                const common_iterator& x, const common_iterator<I2, S2>& y);
            friend iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
                noexcept(noexcept(ranges::iter_move(declval<const I&>())))
                requires input_iterator<I>;

§ 23.5.4.1
template<indirectly_swappable<I> I2, class S2>
friend void iter_swap(const common_iterator<I> x, const common_iterator<I2, S2>& y)
    noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>())))
{
private:
    variant<I, S> v_; // exposition only
};

template<class I, class S>
struct incrementable_traits<common_iterator<I, S>> {
    using difference_type = iter_difference_t<I>;
};

template<input_iterator I, class S>
struct iterator_traits<common_iterator<I, S>> {
    using iterator_concept = see below;
    using iterator_category = see below;
    using value_type = iter_value_t<I>;
    using difference_type = iter_difference_t<I>;
    using pointer = see below;
    using reference = iter_reference_t<I>;
};

23.5.4.2 Associated types [common.iter.types]

The nested typedef-names of the specialization of iterator_traits for common_iterator<I, S> are defined as follows.

- (1.1) iterator_concept denotes forward_iterator_tag if I models forward_iterator; otherwise it denotes input_iterator_tag.
- (1.2) iterator_category denotes forward_iterator_tag if iterator_traits<I>::iterator_category models derived_from<forward_iterator_tag>; otherwise it denotes input_iterator_tag.
- (1.3) If the expression a.operator->() is well-formed, where a is an lvalue of type const common_iterator<I, S>, then pointer denotes the type of that expression. Otherwise, pointer denotes void.

23.5.4.3 Constructors and conversions [common.iter.const]

constexpr common_iterator(I i);

Effects: Initializes v_ as if by v_{in_place_type<I>, std::move(i)}.

constexpr common_iterator(S s);

Effects: Initializes v_ as if by v_{in_place_type<S>, std::move(s)}.

template<class I2, class S2>
    requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
    constexpr common_iterator(const common_iterator<I2, S2>& x);

Preconditions: x.v_.valueless_by_exception() is false.

Effects: Initializes v_ as if by v_{in_place_index<i>, get<i>(x.v_)}, where i is x.v_.index().

template<class I2, class S2>
    requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
    assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
    common_iterator& operator=(const common_iterator<I2, S2>& x);

Preconditions: x.v_.valueless_by_exception() is false.

Effects: Equivalent to:
- (6.1) If v_.index() == x.v_.index(), then get<i>(v_) = get<i>(x.v_).
- (6.2) Otherwise, v_.emplace<i>(get<i>(x.v_)).

where i is x.v_.index().

Returns: *this
23.5.4.4 Accessors

```cpp
decaytpe(auto) operator*();
decaytpe(auto) operator*() const
    requires dereferenceable<const I>;
1    Preconditions: holds_alternative<I>(v_).
2    Effects: Equivalent to: return *get<I>(v_);

decaytpe(auto) operator->() const
    requires see below;
3    The expression in the requires-clause is equivalent to:
        indirectly_readable<const I> &&
        (requires(const I& i) { i.operator->(); } ||
         is_reference_v<iter_reference_t<I>> ||
         constructible_from<iter_value_t<I>, iter_reference_t<I>>)
4    Preconditions: holds_alternative<I>(v_).
5    Effects:
(5.1) If I is a pointer type or if the expression get<I>(v_).operator->() is well-formed, equivalent to:
        return get<I>(v_);
(5.2) Otherwise, if iter_reference_t<I> is a reference type, equivalent to:
        auto&& tmp = *get<I>(v_);
        return addressof(tmp);
(5.3) Otherwise, equivalent to: return proxy(*get<I>(v_)); where proxy is the exposition-only class:
        class proxy {
            iter_value_t<I> keep_;
            proxy(iter_reference_t<I>&& x)
                : keep_(std::move(x)) {} // Public:
            const iter_value_t<I>* operator->() const {
                return addressof(keep_);
            }
        };
```

23.5.4.5 Navigation

```cpp
common_iterator& operator++();
1    Preconditions: holds_alternative<I>(v_).
2    Effects: Equivalent to ++get<I>(v_).
3    Returns: *this.

decaytpe(auto) operator++(int);
4    Preconditions: holds_alternative<I>(v_).
5    Effects: If I models forward_iterator, equivalent to:
            common_iterator tmp = *this;
            ++*this;
            return tmp;
        Otherwise, equivalent to: return get<I>(v_++)
```

23.5.4.6 Comparisons

```cpp
template<class I2, sentinel_for<I> S2>
    requires sentinel_for<S, I2>
    friend bool operator==(const common_iterator<I2>& x, const common_iterator<I2, S2>& y);
1    Preconditions: x.v_.valueless_by_exception() and y.v_.valueless_by_exception() are each false.
```
Returns: true if \( i = j \), and otherwise \( get\langle i\rangle(x.v_) == get\langle j\rangle(y.v_) \), where \( i \) is \( x.v_\).index() and \( j \) is \( y.v_\).index()

```cpp
template<class I2, sentinel_for<I> S2>
requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
friend bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
```

Preconditions: \( x.v_\).valueless_by_exception() and \( y.v_\).valueless_by_exception() are each false.

Returns: true if \( i \) and \( j \) are each 1, and otherwise \( get\langle i\rangle(x.v_) == get\langle j\rangle(y.v_) \), where \( i \) is \( x.v_\).index() and \( j \) is \( y.v_\).index().

```cpp
template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
requires sized_sentinel_for<S, I2>
friend iter_difference_t<I2> operator-(const common_iterator& x, const common_iterator<I2, S2>& y);
```

Preconditions: \( x.v_\).valueless_by_exception() and \( y.v_\).valueless_by_exception() are each false.

Returns: 0 if \( i \) and \( j \) are each 1, and otherwise \( get\langle i\rangle(x.v_) - get\langle j\rangle(y.v_) \), where \( i \) is \( x.v_\).index() and \( j \) is \( y.v_\).index().

### 23.5.4.7 Customizations

```cpp
friend iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
noexcept(noexcept(ranges::iter_move(declval<const I&>())))
requires input_iterator<I>;
```

Preconditions: holds_alternative\(<I>(v_).

Effects: Equivalent to: return ranges::iter_move(get\langle I\rangle(i.v_));

```cpp
template<indirectly_swappable<I> I2, class S2>
friend void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>()))));
```

Preconditions: holds_alternative\(<I>(x.v_) and holds_alternative\(<I2>(y.v_), are each true.

Effects: Equivalent to ranges::iter_swap(get\langle I\rangle(x.v_), get\langle I2\rangle(y.v_)).

### 23.5.5 Default sentinels

```cpp
namespace std {
  struct default_sentinel_t {};
}
```

Class default_sentinel_t is an empty type used to denote the end of a range. It can be used together with iterator types that know the bound of their range (e.g., counted_iterator (23.5.6.1)).

### 23.5.6 Counted iterators

#### 23.5.6.1 Class template counted_iterator

Class template counted_iterator is an iterator adaptor with the same behavior as the underlying iterator except that it keeps track of the distance to the end of its range. It can be used together with default_sentinel in calls to generic algorithms to operate on a range of \( N \) elements starting at a given position without needing to know the end position a priori.

[Example:

```cpp
list<string> s;
// populate the list s with at least 10 strings
vector<string> v;
// copies 10 strings into v:
ranges::copy(counted_iterator(s.begin(), 10), default_sentinel, back_inserter(v));
```

- end example]

Two values \( i1 \) and \( i2 \) of types counted_iterator\(<I1> \) and counted_iterator\(<I2> \) refer to elements of the same sequence if and only if \( next(i1.base(), i1.count()) \) and \( next(i2.base(), i2.count()) \) refer to the same (possibly past-the-end) element.

\[ 23.5.6.1 \]
namespace std {

    template<input_or_output_iterator I>
    class counted_iterator {
    public:
        using iterator_type = I;

struct iterator_traits<counted_iterator<I>> : iterator_traits<I> {
    using pointer = void;
};

23.5.6.2 Constructors and conversions [counted.iter.const]

constexpr counted_iterator(I i, iter_difference_t<I> n);
1
   Preconditions: n >= 0.
2
   Effects: Initializes current with std::move(i) and length with n.

template<class I2>
    requires convertible_to<const I2&, I>
    constexpr counted_iterator(const counted_iterator<I2>& x);
3
   Effects: Initializes current with x.current and length with x.length.

template<class I2>
    requires assignable_from<I&, const I2&>
    constexpr counted_iterator& operator=(const counted_iterator<I2>& x);
4
   Effects: Assigns x.current to current and x.length to length.
5
   Returns: *this.

23.5.6.3 Accessors [counted.iter.access]

constexpr I base() const requires copy_constructible<I>;
1
   Effects: Equivalent to: return current;

constexpr I base() &&;
2
   Returns: std::move(current).

constexpr iter_difference_t<I> count() const noexcept;
3
   Effects: Equivalent to: return length;

23.5.6.4 Element access [counted.iter.elem]

constexpr decltype(auto) operator*();
constexpr decltype(auto) operator*() const
    requires dereferenceable<const I>;
1
   Effects: Equivalent to: return *current;

constexpr decltype(auto) operator[](iter_difference_t<I> n) const
    requires random_access_iterator<I>;
2
   Preconditions: n < length.
Effects: Equivalent to: return current[n];

23.5.6.5 Navigation

constexpr counted_iterator& operator++();

Preconditions: length > 0.

Effects: Equivalent to:
++current;
--length;
return *this;

decltype(auto) operator++(int);

Preconditions: length > 0.

Effects: Equivalent to:
--length;
try { return current++; }
catch(...) { ++length; throw; }

constexpr counted_iterator operator++(int)
requires forward_iterator<I>;

Effects: Equivalent to:
counted_iterator tmp = *this;
+++this;
return tmp;

constexpr counted_iterator& operator--();
requires bidirectional_iterator<I>;

Effects: Equivalent to:

++length;
return *this;

constexpr counted_iterator& operator--(int)
requires bidirectional_iterator<I>;

Effects: Equivalent to:
counted_iterator tmp = *this;
--*this;
return tmp;

constexpr counted_iterator operator+(iter_difference_t<I> n) const
requires random_access_iterator<I>;

Effects: Equivalent to: return counted_iterator(current + n, length - n);

friend constexpr counted_iterator operator+(iter_difference_t<I> n, const counted_iterator& x)
requires random_access_iterator<I>;

Effects: Equivalent to: return x + n;

constexpr counted_iterator& operator+=(iter_difference_t<I> n)
requires random_access_iterator<I>;

Preconditions: n <= length.

Effects: Equivalent to:
current += n;
length -= n;
return *this;
constexpr counted_iterator operator-(iter_difference_t<I> n) const
requires random_access_iterator<I>;

Effects: Equivalent to: return counted_iterator(current - n, length + n);

template<common_with<I> I2>
friend constexpr iter_difference_t<I2> operator-(
    const counted_iterator& x, const counted_iterator<I2>& y);

Preconditions: x and y refer to elements of the same sequence (23.5.6.1).

Effects: Equivalent to: return y.length - x.length;

friend constexpr iter_difference_t<I> operator-(
    const counted_iterator& x, default_sentinel_t);

Effects: Equivalent to: return -x.length;

friend constexpr iter_difference_t<I> operator-(
    default_sentinel_t, const counted_iterator& y);

Effects: Equivalent to: return y.length;

constexpr counted_iterator& operator-=(iter_difference_t<I> n)
requires random_access_iterator<I>;

Preconditions: -n <= length.

Effects: Equivalent to:
    current -= n;
    length += n;
    return *this;

23.5.6.6 Comparisons

friend constexpr bool operator==(const counted_iterator& x, const counted_iterator<I2>& y);

Preconditions: x and y refer to elements of the same sequence (23.5.6.1).

Effects: Equivalent to: return x.length == y.length;

friend constexpr bool operator==(const counted_iterator& x, default_sentinel_t);

Effects: Equivalent to: return x.length == 0;

template<common_with<I> I2>
friend constexpr strong_ordering operator<=>(const counted_iterator& x, const counted_iterator<I2>& y);

Preconditions: x and y refer to elements of the same sequence (23.5.6.1).

Effects: Equivalent to: return y.length <=> x.length;

[Note: The argument order in the Effects: element is reversed because length counts down, not up. — end note]

23.5.6.7 Customizations

friend constexpr iter_rvalue_reference_t<I>
    iter_move(const counted_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)))
requires input_iterator<I>;

Effects: Equivalent to: return ranges::iter_move(i.current);

template<indirectly_swappable<I> I2>
friend constexpr void
    iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

Effects: Equivalent to ranges::iter_swap(x.current, y.current).
23.5.7 Unreachable sentinel

23.5.7.1 Class unreachable_sentinel_t

Class unreachable_sentinel_t can be used with any weakly_incrementable type to denote the "upper bound" of an unbounded interval.

[Example:

```c
char* p;
// set p to point to a character buffer containing newlines
char* nl = find(p, unreachable_sentinel, '\n');
```

Provided a newline character really exists in the buffer, the use of unreachable_sentinel above potentially makes the call to find more efficient since the loop test against the sentinel does not require a conditional branch. — end example]

namespace std {
    struct unreachable_sentinel_t {
        template<weakly_incrementable I>
        friend constexpr bool operator==(unreachable_sentinel_t, const I&) noexcept
            { return false; }
    }
}

23.6 Stream iterators

To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[Example:

```c
partial_sum(istream_iterator<double, char>(cin),
            istream_iterator<double, char>(),
            ostream_iterator<double, char>(cout, "\n"));
```

reads a file containing floating-point numbers from cin, and prints the partial sums onto cout. — end example]

23.6.1 Class template istream_iterator

The class template istream_iterator is an input iterator (23.3.5.2) that reads successive elements from the input stream for which it was constructed.

namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>,
             class Distance = ptrdiff_t>
    class istream_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = T;
        using difference_type = Distance;
        using pointer = const T*;
        using reference = const T&;
        using char_type = charT;
        using traits_type = traits;
        using istream_type = basic_istream<charT,traits>;

        constexpr istream_iterator();
        constexpr istream_iterator(default_sentinel_t);
        istream_iterator(istream_type& s);
        "istream_iterator(const istream_iterator& x) = default;"
        istream_iterator& operator=(const istream_iterator& x) = default;

        const T& operator*() const;
        const T* operator->() const;
        istream_iterator& operator++();
        istream_iterator& operator++(int);

        friend bool operator==(const istream_iterator& i, default_sentinel_t);
    }
}
private:

    basic_istream<charT,traits>* in_stream; // exposition only
    T value; // exposition only

};

The type T shall meet the Cpp17DefaultConstructible, Cpp17CopyConstructible, and Cpp17CopyAssignable requirements.

### 23.6.1.1 Constructors and destructor

```cpp
constexpr istream_iterator();
constexpr istream_iterator(default_sentinel_t);
```

1. **Effects:** Constructs the end-of-stream iterator, value-initializing value.

2. **Postconditions:** in_stream == nullptr is true.

3. **Remarks:** If the initializer T() in the declaration `auto x = T();` is a constant initializer (7.7), then these constructors are constexpr constructors.

```cpp
istream_iterator(istream_type& s);
```

4. **Effects:** Initializes in_stream with addressof(s), value-initializes value, and then calls operator++().

```cpp
istream_iterator(const istream_iterator& x) = default;
```

5. **Postconditions:** in_stream == x.in_stream is true.

6. **Remarks:** If is_trivially_copy_constructible_v<T> is true, then this constructor is trivial.

```cpp
~istream_iterator() = default;
```

7. **Remarks:** If is_trivially_destructible_v<T> is true, then this destructor is trivial.

### 23.6.1.2 Operations

```cpp
const T& operator*() const;
const T* operator->() const;
istream_iterator& operator++();
istream_iterator operator++(int);
```

8. **Preconditions:** in_stream != nullptr is true.

9. **Returns:** value.

10. **Preconditions:** in_stream != nullptr is true.

11. **Returns:** addressof(value).

12. **Effects:** Equivalent to:

    ```cpp
    if (!(*in_stream >> value))
        in_stream = nullptr;
    ```

13. **Returns:** *this.

14. **Preconditions:** in_stream != nullptr is true.

15. **Effects:** Equivalent to:

    ```cpp
    istream_iterator tmp = *this;
    +++this;
    return tmp;
    ```

16. **Returns:** x.in_stream == y.in_stream.
friend bool operator==(const istream_iterator& i, default_sentinel_t);

Returns: \!i.in_stream.

23.6.2 Class template ostream_iterator

ostream_iterator writes (using operator<<) successive elements onto the output stream from which it was constructed. If it was constructed with charT* as a constructor argument, this string, called a delimiter string, is written to the stream after every T is written.

namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>>
    class ostream_iterator {
        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = ptrdiff_t;
            using pointer = void;
            using reference = void;
            using char_type = charT;
            using traits_type = traits;
            using ostream_type = basic_ostream<charT,traits>;

            constexpr ostream_iterator() noexcept = default;
            ostream_iterator(ostream_type& s);
            ostream_iterator(ostream_type& s, const charT* delimiter);
            "ostream_iterator();
            ostream_iterator& operator=(const ostream_iterator& x);
            ostream_iterator& operator=(const T& value);
            ostream_iterator& operator*();
            ostream_iterator& operator++();
            ostream_iterator& operator++(int);

        private:
            basic_ostream<charT,traits>* out_stream = nullptr; // exposition only
            const charT* delim = nullptr; // exposition only
        }
    }

23.6.2.1 Constructors and destructor

ostream_iterator(ostream_type& s);

Effects: Initializes out_stream with addressof(s) and delim with nullptr.

ostream_iterator(ostream_type& s, const charT* delimiter);

Effects: Initializes out_stream with addressof(s) and delim with delimiter.

23.6.2.2 Operations

ostream_iterator& operator=(const T& value);

Effects: As if by:

*out_stream << value;
if (delim)
    *out_stream << delim;
return *this;

ostream_iterator& operator*();

Returns: *this.

ostream_iterator& operator++();
ostream_iterator& operator++(int);

Returns: *this.
The class template istreambuf_iterator defines an input iterator (23.3.5.2) that reads successive characters from the streambuf for which it was constructed. operator* provides access to the current input character, if any. Each time operator++ is evaluated, the iterator advances to the next input character. If the end of stream is reached (streambuf_type::sgetc() returns traits::eof()), the iterator becomes equal to the end-of-stream iterator value. The default constructor istreambuf_iterator() and the constructor istreambuf_iterator(nullptr) both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of istreambuf_iterator shall have a trivial copy constructor, a constexpr default constructor, and a trivial destructor.

The result of operator*() on an end-of-stream iterator is undefined. For any other iterator value a char_type value is returned. It is impossible to assign a character via an input iterator.

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class istreambuf_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = charT;
        using difference_type = typename traits::off_type;
        using pointer = unspecified;
        using reference = charT;
        using char_type = charT;
        using traits_type = traits;
        using int_type = typename traits::int_type;
        using streambuf_type = basic_streambuf<charT,traits>;
        using istream_type = basic_istream<charT,traits>;

        class proxy; // exposition only
    
    constexpr istreambuf_iterator() noexcept;
    constexpr istreambuf_iterator(default_sentinel_t) noexcept;
    istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
    ~istreambuf_iterator() = default;
    istreambuf_iterator(istream_type& s) noexcept;
    istreambuf_iterator(streambuf_type* s) noexcept;
    istreambuf_iterator(const proxy& p) noexcept;
    istreambuf_iterator& operator=(const istreambuf_iterator&) noexcept = default;
    charT operator*() const;
    istreambuf_iterator& operator++();
    proxy operator++(int);
    bool equal(const istreambuf_iterator& b) const;
    
    friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);

    private:
        streambuf_type* sbuf_; // exposition only
    };
};

23.6.3.1 Class istreambuf_iterator::proxy

Class istreambuf_iterator::proxy is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class istreambuf_iterator::proxy provides a temporary placeholder as the return value of the post-increment operator (operator++). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

namespace std {
    template<class charT, class traits>
    class istreambuf_iterator<charT, traits>::proxy { // exposition only
        charT keep_;
        basic_streambuf<charT,traits>* sbuf_;
        proxy(charT c, basic_streambuf<charT,traits>* sbuf) : keep_(c), sbuf_(sbuf) {} 
    };
}

§ 23.6.3.1 932
23.6.3.2 Constructors

For each `istreambuf_iterator` constructor in this subclause, an end-of-stream iterator is constructed if and only if the exposition-only member `sbuf_` is initialized with a null pointer value.

```cpp
constexpr istreambuf_iterator() noexcept;
constexpr istreambuf_iterator(default_sentinel_t) noexcept;
istreambuf_iterator(istream_type& s) noexcept;
istreambuf_iterator(streambuf_type* s) noexcept;
istreambuf_iterator(const proxy& p) noexcept;
```

23.6.3.3 Operations

```cpp
charT operator*() const;
istreambuf_iterator& operator++();
proxy operator++(int);
bool equal(const istreambuf_iterator& b) const;
template<class charT, class traits>
bool operator==(const istreambuf_iterator<charT, traits>& a,
               const istreambuf_iterator<charT, traits>& b);
friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);
```

23.6.4 Class template `ostreambuf_iterator`

The class template `ostreambuf_iterator` writes successive characters onto the output stream from which it was constructed.

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class ostreambuf_iterator {
    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = ptrdiff_t;
        using pointer = void;
        using reference = void;
        using char_type = charT;
        using traits_type = traits;
    }
}
```
using streambuf_type = basic_streambuf<charT,traits>;
using ostream_type = basic_ostream<charT,traits>;

constexpr ostreambuf_iterator() noexcept = default;
ostreambuf_iterator(ostream_type& s) noexcept;
ostreambuf_iterator(streambuf_type* s) noexcept;
ostreambuf_iterator& operator=(charT c);
ostreambuf_iterator& operator*();
ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);

bool failed() const noexcept;

private:
    streambuf_type* sbuf_ = nullptr;   // exposition only
};

23.6.4.1 Constructors

ostreambuf_iterator(ostream_type& s) noexcept;
1    Preconditions: s.rdbuf() is not a null pointer.
2    Effects: Initializes sbuf_ with s.rdbuf().

ostreambuf_iterator(streambuf_type* s) noexcept;
3    Preconditions: s is not a null pointer.
4    Effects: Initializes sbuf_ with s.

23.6.4.2 Operations

ostreambuf_iterator& operator=(charT c);
1    Effects: If failed() yields false, calls sbuf_ -> sputc(c); otherwise has no effect.
2    Returns: *this.

ostreambuf_iterator& operator*();
3    Returns: *this.

ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);
4    Returns: *this.

bool failed() const noexcept;
5    Returns: true if in any prior use of member operator=, the call to sbuf_ -> sputc() returned traits::eof();
or false otherwise.

23.7 Range access

In addition to being available via inclusion of the <iterator> header, the function templates in 23.7 are available when any of the following headers are included: <array> (22.3.2), <deque> (22.3.3), <forward_list> (22.3.4), <list> (22.3.5), <map> (22.4.2), <regex> (30.4), <set> (22.4.3), <span> (22.7.2), <string> (21.3.1), <string_view> (21.4.1), <unordered_map> (22.5.2), <unordered_set> (22.5.3), and <vector> (22.3.6). Each of these templates is a designated customization point (16.5.4.2.1).

template<class C> constexpr auto begin(C& c) -> decltype(c.begin());
template<class C> constexpr auto begin(const C& c) -> decltype(c.begin());
2    Returns: c.begin().

template<class C> constexpr auto end(C& c) -> decltype(c.end());
template<class C> constexpr auto end(const C& c) -> decltype(c.end());
3    Returns: c.end().
template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
Returns: array.

template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
Returns: array + N.

template<class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
-> decltype(std::begin(c));
Returns: std::begin(c).

template<class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
-> decltype(std::end(c));
Returns: std::end(c).

template<class C> constexpr auto rbegin(C& c) -> decltype(c.rbegin());
template<class C> constexpr auto rbegin(const C& c) -> decltype(c.rbegin());
Returns: c.rbegin().

template<class C> constexpr auto rend(C& c) -> decltype(c.rend());
template<class C> constexpr auto rend(const C& c) -> decltype(c.rend());
Returns: c.rend().

template<class T, size_t N> constexpr reverse_iterator<T*> rbegin(T (&array)[N]);
Returns: reverse_iterator<T*>(array + N).

template<class T, size_t N> constexpr reverse_iterator<T*> rend(T (&array)[N]);
Returns: reverse_iterator<T*>(array).

template<class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il);
Returns: reverse_iterator<const E*>(il.end()).

template<class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il);
Returns: reverse_iterator<const E*>(il.begin()).

template<class C> constexpr auto crbegin(const C& c) -> decltype(std::rbegin(c));
Returns: std::rbegin(c).

template<class C> constexpr auto crend(const C& c) -> decltype(std::rend(c));
Returns: std::rend(c).

template<class C> constexpr auto size(const C& c) -> decltype(c.size());
Returns: c.size().

template<class T, size_t N> constexpr size_t size(const T (&array)[N]) noexcept;
Returns: N.

template<class C> constexpr auto ssize(const C& c)
-> common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>;
Effects: Equivalent to:
return static_cast<common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>>(c.size());

template<class C> std::tuple<ptrdiff_t, size_t> size(const C& c)
returns: std::size_t(c.size()), std::ptrdiff_t(c.size());

§ 23.7 935
template<class T, size_t N> [[nodiscard]] constexpr bool empty(const T (&array)[N]) noexcept;

Returns: false.

template<class E> [[nodiscard]] constexpr bool empty(initializer_list<E> il) noexcept;

Returns: il.size() == 0.

template<class C> constexpr auto data(C& c) -> decltype(c.data());
template<class C> constexpr auto data(const C& c) -> decltype(c.data());

Returns: c.data().

template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;

Returns: array.

template<class E> constexpr const E* data(initializer_list<E> il) noexcept;

Returns: il.begin().
24 Ranges library [ranges]

24.1 General [ranges.general]

This Clause describes components for dealing with ranges of elements.

The following subclauses describe range and view requirements, and components for range primitives as summarized in Table 90.

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>24.3 Range access</td>
<td>&lt;ranges&gt;</td>
</tr>
<tr>
<td>24.4 Requirements</td>
<td></td>
</tr>
<tr>
<td>24.5 Range utilities</td>
<td></td>
</tr>
<tr>
<td>24.6 Range factories</td>
<td></td>
</tr>
<tr>
<td>24.7 Range adaptors</td>
<td></td>
</tr>
</tbody>
</table>

24.2 Header <ranges> synopsis [ranges.syn]

```cpp
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.1
#include <iterator>  // see 23.2

    template<class I, class S, ranges::subrange_kind K>
    struct tuple_element<1, ranges::subrange<I, S, K>> {
        using type = S;
    };

} // std

1 Within this Clause, for an integer-like type X (23.3.4.4), make_unsigned-like-t<X> denotes make_unsigned_t<X> if X is an integer type; otherwise, it denotes a corresponding unspecified unsigned-integer-like type of the same width as X. For an expression x of type X, to_unsigned-like(x) is x explicitly converted to make_unsigned-like-t<X>.
24.3 Range access

1 In addition to being available via inclusion of the `<ranges>` header, the customization point objects in 24.3 are available when `<iterator>` is included.

2 Within this subclause, the reified object of a subexpression `E` denotes

   - the same object as `E` if `E` is a glvalue, or
   - the result of applying the temporary materialization conversion (7.3.4) to `E` otherwise.

24.3.1 ranges::begin

1 The name ranges::begin denotes a customization point object (16.4.2.2.6).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

   - If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, ranges::begin(`E`) is ill-formed.
   - Otherwise, if `T` is an array type (6.8.2) and `remove_all_extents_t<T>` is an incomplete type, ranges::begin(`E`) is ill-formed with no diagnostic required.
   - Otherwise, if `T` is an array type, ranges::begin(`E`) is expression-equivalent to `t + 0`.
   - Otherwise, if `decay-copy(t.begin())` is a valid expression whose type models input_or_output_iterator, ranges::begin(`E`) is expression-equivalent to `decay-copy(t.begin())`.
   - Otherwise, if `T` is a class or enumeration type and `decay-copy(begin(t))` is a valid expression whose type models input_or_output_iterator with overload resolution performed in a context in which unqualified lookup for `begin` finds only the declarations

        ```cpp
        void begin(auto&) = delete;
        void begin(const auto&) = delete;
        ```

        then ranges::begin(`E`) is expression-equivalent to `decay-copy(begin(t))` with overload resolution performed in the above context.
   - Otherwise, ranges::begin(`E`) is ill-formed.

3 [Note: Diagnosable ill-formed cases above result in substitution failure when ranges::begin(`E`) appears in the immediate context of a template instantiation. — end note]

4 [Note: Whenever ranges::begin(`E`) is a valid expression, its type models input_or_output_iterator. — end note]

24.3.2 ranges::end

1 The name ranges::end denotes a customization point object (16.4.2.2.6).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

   - If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, ranges::end(`E`) is ill-formed.
   - Otherwise, if `T` is an array type (6.8.2) and `remove_all_extents_t<T>` is an incomplete type, ranges::end(`E`) is ill-formed with no diagnostic required.
   - Otherwise, if `T` is an array of unknown bound, ranges::end(`E`) is ill-formed.
   - Otherwise, if `T` is an array, ranges::end(`E`) is expression-equivalent to `t.extent.v<T>`.
   - Otherwise, if `decay-copy(t.end())` is a valid expression whose type models sentinel_for<iterator_end_t<T>> then ranges::end(`E`) is expression-equivalent to `decay-copy(t.end())`.
   - Otherwise, if `T` is a class or enumeration type and `decay-copy(end(t))` is a valid expression whose type models sentinel_for<iterator_end_t<T>> with overload resolution performed in a context in which unqualified lookup for `end` finds only the declarations

        ```cpp
        void end(auto&) = delete;
        void end(const auto&) = delete;
        ```

        then ranges::end(`E`) is expression-equivalent to `decay-copy(end(t))` with overload resolution performed in the above context.
   - Otherwise, ranges::end(`E`) is ill-formed.
24.3.3 ranges::cbegin  
1 The name ranges::cbegin denotes a customization point object (16.4.2.2.6). The expression ranges::cbegin(E) for a subexpression E of type T is expression-equivalent to:

- (1.1) ranges::begin(static_cast<const T&>(E)) if E is an lvalue.
- (1.2) Otherwise, ranges::begin(static_cast<const T&&>(E)).

2 [Note: Whenever ranges::cbegin(E) is a valid expression, the types S and I of ranges::end(E) and ranges::cbegin(E) model sentinel_for<S, I>. — end note]

24.3.4 ranges::cend  
1 The name ranges::cend denotes a customization point object (16.4.2.2.6). The expression ranges::cend(E) for a subexpression E of type T is expression-equivalent to:

- (1.1) ranges::end(static_cast<const T&>(E)) if E is an lvalue.
- (1.2) Otherwise, ranges::end(static_cast<const T&&>(E)).

2 [Note: Whenever ranges::cend(E) is a valid expression, the types S and I of ranges::cend(E) and ranges::cbegin(E) model sentinel_for<S, I>. — end note]

24.3.5 ranges::rbegin  
1 The name ranges::rbegin denotes a customization point object (16.4.2.2.6).

2 Given a subexpression E with type T, let t be an lvalue that denotes the reified object for E. Then:

- (2.1) If E is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::rbegin(E) is ill-formed.
- (2.2) Otherwise, if T is an array type (6.8.2) and remove_all_extents_t<T> is an incomplete type, ranges::rbegin(E) is ill-formed with no diagnostic required.
- (2.3) Otherwise, if decay_copy(t.rbegin()) is a valid expression whose type models input_or_output_iterator, ranges::rbegin(E) is expression-equivalent to decay_copy(t.rbegin()).
- (2.4) Otherwise, if T is a class or enumeration type and decay_copy(rbegin(t)) is a valid expression whose type models input_or_output_iterator with overload resolution performed in a context in which unqualified lookup for rbegin finds only the declarations

```cpp
void rbegin(auto&) = delete;
void rbegin(const auto&) = delete;
```

then ranges::rbegin(E) is expression-equivalent to decay_copy(rbegin(t)) with overload resolution performed in the above context.

- (2.5) Otherwise, if both ranges::begin(t) and ranges::end(t) are valid expressions of the same type which models bidirectional_iterator (23.3.4.12), ranges::rbegin(E) is expression-equivalent to make_reverse_iterator(ranges::end(t)).
- (2.6) Otherwise, ranges::rbegin(E) is ill-formed.

3 [Note: Diagnosable ill-formed cases above result in substitution failure when ranges::rbegin(E) appears in the immediate context of a template instantiation. — end note]

4 [Note: Whenever ranges::rbegin(E) is a valid expression, its type models input_or_output_iterator. — end note]

24.3.6 ranges::rend  
1 The name ranges::rend denotes a customization point object (16.4.2.2.6).

2 Given a subexpression E with type T, let t be an lvalue that denotes the reified object for E. Then:

- (2.1) If E is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::rend(E) is ill-formed.
Otherwise, if \( T \) is an array type (6.8.2) and \( \text{remove\_all\_extents\_t\,<T>\text{\,}} \) is an incomplete type, \( \text{ranges::rend(E)} \) is ill-formed with no diagnostic required.

Otherwise, if \( \text{decay\,-\,copy(t.rend())} \) is a valid expression whose type models sentinel\_for\(<\text{decltype(ranges::rbegin(E))}>\) then \( \text{ranges::rend(E)} \) is expression-equivalent to \( \text{decay\,-\,copy(t.rend())} \).

Otherwise, if \( T \) is a class or enumeration type and \( \text{decay\,-\,copy(rrend(t))} \) is a valid expression whose type models sentinel\_for\(<\text{decltype(ranges::rbegin(E))}>\) with overload resolution performed in a context in which unqualified lookup for \( \text{rend} \) finds only the declarations

```c
void rend(auto&) = delete;
void rend(const auto&) = delete;
```

then \( \text{ranges::rend(E)} \) is expression-equivalent to \( \text{decay\,-\,copy(rrend(t))} \) with overload resolution performed in the above context.

Otherwise, if both \( \text{ranges::begin(t)} \) and \( \text{ranges::end(t)} \) are valid expressions of the same type which models bidirectional\_iterator (23.3.4.12), then \( \text{ranges::rend(E)} \) is expression-equivalent to \( \text{make\,-\,reverse\_iterator(ranges::begin(t))} \).

Otherwise, \( \text{ranges::rend(E)} \) is ill-formed.

### range.access.crbegin

The name \( \text{ranges::crbegin} \) denotes a customization point object (16.4.2.2.6). The expression \( \text{ranges::crbegin(E)} \) for a subexpression \( E \) of type \( T \) is expression-equivalent to:

1. \( \text{ranges::rbegin(static\,\_\,cast<\text{const T&}\,(E)} \) if \( E \) is an lvalue.
2. Otherwise, \( \text{ranges::rbegin(static\,\_\,cast<\text{const T&}\,(E)} \).

### range.access.crend

The name \( \text{ranges::crend} \) denotes a customization point object (16.4.2.2.6). The expression \( \text{ranges::crend(E)} \) for a subexpression \( E \) of type \( T \) is expression-equivalent to:

1. \( \text{ranges::rend(static\,\_\,cast<\text{const T&}\,(E)} \) if \( E \) is an lvalue.
2. Otherwise, \( \text{ranges::rend(static\,\_\,cast<\text{const T&}\,(E)} \).

### range.prim.size

The name \( \text{ranges::size} \) denotes a customization point object (16.4.2.2.6).

Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:

1. If \( T \) is an array of unknown bound (9.3.3.4), \( \text{ranges::size(E)} \) is ill-formed.
2. Otherwise, if \( T \) is an array type, \( \text{ranges::size(E)} \) is expression-equivalent to \( \text{decay\,-\,copy(extent\_v\,<T>)} \).
3. Otherwise, if \( \text{disable\,\_\,sized\_\,range<\text{remove\,\_\,cv\_\,t\,<T>}>\,(24.4.3)\,\text{is\,false\,and\,decay\,-\,copy(t.size())\,is\,a\,valid\,expression\,of\,integer\,-\,like\,type\,(23.3.4.4)}\), \( \text{ranges::size(E)} \) is expression-equivalent to \( \text{decay\,-\,copy(t.size())} \).
4. Otherwise, if \( T \) is a class or enumeration type, \( \text{disable\,\_\,sized\,\,range<\text{remove\,\,cv\,\,t\,<T>}>\,(24.4.3)\,\text{is\,false\,and\,decay\,-\,copy(size(t))\,is\,a\,valid\,expression\,of\,integer\,-\,like\,type\,with\,overload\,resolution\,performed\,in\,a\,context\,in\,which\,unqualified\,lookup\,for\,\text{size}\,\,finds\,\,only\,\,the\,\,declarations} \)

```c
void size(auto&) = delete;
void size(const auto&) = delete;
```

then \( \text{ranges::size(E)} \) is expression-equivalent to \( \text{decay\,-\,copy(size(t))} \) with overload resolution performed in the above context.
© ISO/IEC

— Otherwise, if `to_unsigned-like(ranges::end(t) - ranges::begin(t))` (24.2) is a valid expression and the types `I` and `S` of `ranges::begin(t)` and `ranges::end(t)` (respectively) model both `sized_sentinel_for<S, I>` (23.3.4.8) and `forward_iterator<I>`, then `ranges::size(E)` is expression-equivalent to `to_unsigned-like(ranges::end(t) - ranges::begin(t))`.

— Otherwise, `ranges::size(E)` is ill-formed.

3 [Note: Diagnosable ill-formed cases above result in substitution failure when `ranges::size(E)` appears in the immediate context of a template instantiation. — end note]

4 [Note: Whenever `ranges::size(E)` is a valid expression, its type is integer-like. — end note]

### 24.3.10 ranges::size

The name `ranges::size` denotes a customization point object (16.4.2.2.6). The expression `ranges::size(E)` for a subexpression `E` of type `T` is expression-equivalent to:

1 If `range_difference_t<T>` has width less than `ptrdiff_t`, `static_cast<ptrdiff_t>(ranges::size(E))`.

2 Otherwise, `static_cast<range_difference_t<T>>(ranges::size(E))`.

### 24.3.11 ranges::empty

The name `ranges::empty` denotes a customization point object (16.4.2.2.6). Given a subexpression `ranges::empty(E)` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

1 If `T` is an array of unknown bound (6.8.2), `ranges::empty(E)` is ill-formed.

2 Otherwise, if `bool(t.empty())` is a valid expression, `ranges::empty(E)` is expression-equivalent to `bool(t.empty())`.

3 Otherwise, if `(ranges::size(t) == 0)` is a valid expression, `ranges::empty(E)` is expression-equivalent to `(ranges::size(t) == 0)`.

4 Otherwise, if `bool(ranges::begin(t) == ranges::end(t))` is a valid expression and the type of `ranges::begin(t)` models `forward_iterator`, `ranges::empty(E)` is expression-equivalent to `bool(ranges::begin(t) == ranges::end(t))`.

5 Otherwise, `ranges::empty(E)` is ill-formed.

3 [Note: Diagnosable ill-formed cases above result in substitution failure when `ranges::empty(E)` appears in the immediate context of a template instantiation. — end note]

4 [Note: Whenever `ranges::empty(E)` is a valid expression, it has type `bool`. — end note]

### 24.3.12 ranges::data

The name `ranges::data` denotes a customization point object (16.4.2.2.6). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

1 If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::data(E)` is ill-formed.

2 Otherwise, if `T` is an array type (6.8.2) and `remove_all_extents_t<T>` is an incomplete type, `ranges::data(E)` is ill-formed with no diagnostic required.

3 Otherwise, if `decay_copy(t.data())` is a valid expression of pointer to object type, `ranges::data(E)` is expression-equivalent to `decay_copy(t.data())`.

4 Otherwise, if `ranges::begin(t)` is a valid expression whose type models `contiguous_iterator`, `ranges::data(E)` is expression-equivalent to `to_address(ranges::begin(E))`.

5 Otherwise, `ranges::data(E)` is ill-formed.

3 [Note: Diagnosable ill-formed cases above result in substitution failure when `ranges::data(E)` appears in the immediate context of a template instantiation. — end note]

4 [Note: Whenever `ranges::data(E)` is a valid expression, it has type `pointer` to `object` type. — end note]

### 24.3.13 ranges::cdata

The name `ranges::cdata` denotes a customization point object (16.4.2.2.6). The expression `ranges::cdata(E)` for a subexpression `E` of type `T` is expression-equivalent to:

1 `ranges::data(static_cast<const T&>(E))` if `E` is an lvalue.
24.4 Range requirements

24.4.1 General

Ranges are an abstraction that allow a C++ program to operate on elements of data structures uniformly. Calling `ranges::begin` on a range returns an object whose type models `input_or_output_iterator` (23.3.4.6). Calling `ranges::end` on a range returns an object whose type `S`, together with the type `I` of the object returned by `ranges::begin`, models `sentinel_for<S, I>`. The library formalizes the interfaces, semantics, and complexity of ranges to enable algorithms and range adaptors that work efficiently on different types of sequences.

The range concept requires that `ranges::begin` and `ranges::end` return an iterator and a sentinel, respectively. The sized_range concept refines range with the requirement that `ranges::size` be amortized $O(1)$. The view concept specifies requirements on a range type with constant-time destruction and move operations.

Several refinements of range group requirements that arise frequently in concepts and algorithms. Common ranges are ranges for which `ranges::begin` and `ranges::end` return objects of the same type. Random access ranges are ranges for which `ranges::begin` returns a type that models `random_access_iterator` (23.3.4.13). (Contiguous, bidirectional, forward, input, and output ranges are defined similarly.) Viewable ranges can be converted to views.

24.4.2 Ranges

The range concept defines the requirements of a type that allows iteration over its elements by providing an iterator and sentinel that denote the elements of the range.

```cpp
template<class T>
concept range =
    requires(T& t) {
    ranges::begin(t); // sometimes equality-preserving (see below)
    ranges::end(t);
    };
```

The required expressions `ranges::begin(t)` and `ranges::end(t)` of the range concept do not require implicit expression variations (18.2).

Given an expression `t` such that `decltype((t))` is `T&`, `T` models range only if

1. `[ranges::begin(t), ranges::end(t))` denotes a range (23.3.1),
2. both `ranges::begin(t)` and `ranges::end(t)` are amortized constant time and non-modifying, and
3. if the type of `ranges::begin(t)` models `forward_iterator`, `ranges::begin(t)` is equality-preserving.

[Note: Equality preservation of both `ranges::begin` and `ranges::end` enables passing a range whose iterator type models `forward_iterator` to multiple algorithms and making multiple passes over the range by repeated calls to `ranges::begin` and `ranges::end`. Since `ranges::begin` is not required to be equality-preserving when the return type does not model `forward_iterator`, repeated calls might not return equal values or might not be well-defined; `ranges::begin` should be called at most once for such a range. — end note]

```cpp
template<class T>
concept borrowed_range =
    range<T> &&
    (is_lvalue_reference_v<T> || enable_borrowed_range<remove_cvref_t<T>>);
```

Given an expression `E` such that `decltype((E))` is `T`, `T` models `borrowed_range` only if the validity of iterators obtained from the object denoted by `E` is not tied to the lifetime of that object.

[Note: Since the validity of iterators is not tied to the lifetime of an object whose type models `borrowed_range`, a function can accept arguments of such a type by value and return iterators obtained from it without danger of dangling. — end note]

```cpp
inline constexpr bool enable_borrowed_range = false;
```

Remarks: Pursuant to 16.5.4.2.1, users may specialize `enable_borrowed_range` for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7) and have type `const bool`.

§ 24.4.2
[Example: Each specialization $S$ of class template subrange (24.5.3) models borrowed_range because

(8.1) enable_borrowed_range<$S$> is specialized to have the value true, and

(8.2) $S$’s iterators do not have validity tied to the lifetime of an $S$ object because they are "borrowed" from some other range.

—end example]

24.4.3 Sized ranges

The sized_range concept refines range with the requirement that the number of elements in the range can be determined in amortized constant time using ranges::size.

```cpp
template<class T>
concept sized_range =
    range<T> &&
    requires(T& t) { ranges::size(t); };
```

Given an lvalue $t$ of type remove_reference_t<T>, $T$ models sized_range only if

(2.1) ranges::size($t$) is amortized $O(1)$, does not modify $t$, and is equal to ranges::distance($t$), and

(2.2) if iterator_t<T> models forward_iterator, ranges::size($t$) is well-defined regardless of the evaluation of ranges::begin($t$). [Note: ranges::size($t$) is otherwise not required to be well-defined after evaluating ranges::begin($t$). For example, ranges::size($t$) might be well-defined for a sized_range whose iterator type does not model forward_iterator only if evaluated before the first call to ranges::begin($t$). —end note]

```cpp
template<class>
inline constexpr bool disable_sized_range = false;
```

Remarks: Pursuant to 16.5.4.2.1, users may specialize disable_sized_range for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7) and have type const bool.

[Note: disable_sized_range allows use of range types with the library that satisfy but do not in fact model sized_range. —end note]

24.4.4 Views

The view concept specifies the requirements of a range type that has constant time move construction, move assignment, and destruction; that is, the cost of these operations is independent of the number of elements in the view.

```cpp
template<class T>
concept view =
    range<T> && movable<T> && default_initializable<T> && enable_view<T>;
```

$T$ models view only if:

(2.1) $T$ has $O(1)$ move construction; and

(2.2) $T$ has $O(1)$ move assignment; and

(2.3) $T$ has $O(1)$ destruction; and

(2.4) copy_constructible<T> is false, or $T$ has $O(1)$ copy construction; and

(2.5) copyable<T> is false, or $T$ has $O(1)$ copy assignment.

[Example: Examples of views are:

(1.1) A range type that wraps a pair of iterators.

(1.2) A range type that holds its elements by shared_ptr and shares ownership with all its copies.

(1.3) A range type that generates its elements on demand.

Most containers (Clause 22) are not views since destruction of the container destroys the elements, which cannot be done in constant time. —end example]

Since the difference between range and view is largely semantic, the two are differentiated with the help of enable_view.
template<class T>
inline constexpr bool enable_view = derived_from<T, view_base>;

Remarks: Pursuant to 16.5.4.2.1, users may specialize enable_view to true for cv-qualified program-defined types which model view, and false for types which do not. Such specializations shall be usable in constant expressions (7.7) and have type const bool.

24.4.5 Other range refinements  [range.refinements]

The output_range concept specifies requirements of a range type for which ranges::begin returns a model of output_iterator (23.3.4.10). input_range, forward_range, bidirectional_range, and random_access_range are defined similarly.

template<class R, class T>
concept output_range =
range<R> && output_iterator<iterator_t<R>, T>;

template<class T>
concept input_range =
range<T> && input_iterator<iterator_t<T>>;

template<class T>
concept forward_range =
input_range<T> && forward_iterator<iterator_t<T>>;

template<class T>
concept bidirectional_range =
forward_range<T> && bidirectional_iterator<iterator_t<T>>;

template<class T>
concept random_access_range =
bidirectional_range<T> && random_access_iterator<iterator_t<T>>;

contiguous_range additionally requires that the ranges::data customization point object (24.3.12) is usable with the range.

template<class T>
concept contiguous_range =
random_access_range<T> && contiguous_iterator<iterator_t<T>> &&
requires(T& t) {
{ ranges::data(t) } -> same_as<add_pointer_t<range_reference_t<T>>>;
};

Given an expression t such that decltype((t)) is T&, T models contiguous_range only if to_address(ranges::begin(t)) == ranges::data(t) is true.

The common_range concept specifies requirements of a range type for which ranges::begin and ranges::end return objects of the same type. [Example: The standard containers (Clause 22) model common_range. —end example]

template<class T>
concept common_range =
range<T> && same_as<iterator_t<T>, sentinel_t<T>>;

The viewable_range concept specifies the requirements of a range type that can be converted to a view safely.

template<class T>
concept viewable_range =
range<T> && (borrowed_range<T> || view<remove_cvref_t<T>>);

24.5 Range utilities  [range.utility]

The components in this subclause are general utilities for representing and manipulating ranges.

24.5.1 Helper concepts  [range.utility.helpers]

Many of the types in subclause 24.5 are specified in terms of the following exposition-only concepts:

§ 24.5.1 948
template<class R>
concept simple-view = // exposition only
  view<R> && range<const R> &&
  same_as<iterator_t<R>, iterator_t<const R>> &&
  same_as<sentinel_t<R>, sentinel_t<const R>>;

template<class I>
concept has-arrow = // exposition only
  input_iterator<I> && (is_pointer_v<I> || requires(I i) { i.operator->(); });

template<class T, class U>
concept not-same-as = // exposition only
  !same_as<remove_cvref_t<T>, remove_cvref_t<U>>;

24.5.2 View interface [view.interface]

The class template `view_interface` is a helper for defining view-like types that offer a container-like interface. It is parameterized with the type that is derived from it.

namespace std::ranges {
  template<class D>
  requires is_class_v<D> && same_as<D, remove_cv_t<D>>
  class view_interface : public view_base {
    private:
      constexpr D& derived() noexcept { // exposition only
        return static_cast<D&>(*this);
      }
      constexpr const D& derived() const noexcept {
        return static_cast<const D&>(*this);
      }
    public:
      constexpr bool empty() requires forward_range<D> {
        return ranges::begin(derived()) == ranges::end(derived());
      }
      constexpr bool empty() const requires forward_range<const D> {
        return ranges::begin(derived()) == ranges::end(derived());
      }
      constexpr explicit operator bool() requires requires { ranges::empty(derived()); } {
        return !ranges::empty(derived());
      }
      constexpr explicit operator bool() const requires requires { ranges::empty(derived()); } {
        return !ranges::empty(derived());
      }
      constexpr auto data() requires contiguous_iterator<iterator_t<D>> {
        return to_address(ranges::begin(derived()));
      }
      constexpr auto data() const requires range<const D> && contiguous_iterator<iterator_t<const D>> {
        return to_address(ranges::begin(derived()));
      }
      constexpr auto size() requires forward_range<D> &&
        sized_sentinel_for<sentinel_t<D>, iterator_t<D>> {
        return ranges::end(derived()) - ranges::begin(derived());
      }
      constexpr auto size() const requires forward_range<const D> &&
        sized_sentinel_for<sentinel_t<const D>, iterator_t<const D>> {
        return ranges::end(derived()) - ranges::begin(derived());
      }
  }
}
constexpr decltype(auto) front() requires forward_range<D>;
constexpr decltype(auto) front() const requires forward_range<const D>;

customexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;

24.5.3.1 Constructors and conversions

constexpr subrange(convertible-to-non-slicing<I> auto i, S s) requires (!StoreSize);
  Preconditions: [i, s) is a valid range.
  Effects: Initializes begin_ with std::move(i) and end_ with s.

constexpr subrange(convertible-to-non-slicing<I> auto i, S s, make_unsigned_like_t<iter_difference_t<I>> n)
  requires (K == subrange_kind::sized);
  Preconditions: [i, s) is a valid range, and n == to_unsigned_like(ranges::distance(i, s)).
  Effects: Initializes begin_ with std::move(i) and end_ with s. If StoreSize is true, initializes size_ with n.
  [Note: Accepting the length of the range and storing it to later return from size() enables subrange to model sized_range even when it stores an iterator and sentinel that do not model sized_sentinel_for. — end note]

template<not_same_as<subrange> R>
  requires borrowed_range<R> &&
    convertible-to-non-slicing<iterator_t<R>, I> &&
    convertible_to<sentinel_t<R>, S>
  constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);
  Effects: Equivalent to:
If `StoreSize` is true, subrange\(r\), ranges::size\(r\).

Otherwise, subrange\(\text{ranges}::\text{begin}(r)\), ranges::end\(r\).

\begin{verbatim}
template<not_same_as<subrange> PairLike>
    requires pair_like_convertible_from<PairLike, const I&, const S&>
constexpr operator PairLike() const;
\end{verbatim}

\textbf{Effects:} Equivalent to: return PairLike(begin_, end_);

### 24.5.3.2 Accessors

\begin{verbatim}
constexpr I begin() const requires copyable<I>;
\end{verbatim}

\textbf{Effects:} Equivalent to: return begin_;

\begin{verbatim}
[[nodiscard]] constexpr I begin() requires (!copyable<I>);
\end{verbatim}

\textbf{Effects:} Equivalent to: return std::move(begin_);

\begin{verbatim}
constexpr S end() const;
\end{verbatim}

\textbf{Effects:} Equivalent to: return end_;

\begin{verbatim}
constexpr bool empty() const;
\end{verbatim}

\textbf{Effects:} Equivalent to: return begin_ == end_;

\begin{verbatim}
constexpr make_unsigned_like_t<iter_difference_t<I>> size() const
    requires (K == subrange_kind::sized);
\end{verbatim}

\textbf{Effects:}

\begin{enumerate}
  \item If `StoreSize` is true, equivalent to: return size_;
  \item Otherwise, equivalent to: return to_unsigned_like(end_ - begin_);
\end{enumerate}

\begin{verbatim}
[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) const &
    requires forward_iterator<I>;
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
    auto tmp = *this;
    tmp.advance(n);
    return tmp;
\end{verbatim}

\begin{verbatim}
[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) &&;
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
    advance(n);
    return std::move(*this);
\end{verbatim}

\begin{verbatim}
[[nodiscard]] constexpr subrange prev(iter_difference_t<I> n = 1) const
    requires bidirectional_iterator<I>;
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
    auto tmp = *this;
    tmp.advance(-n);
    return tmp;
\end{verbatim}

\begin{verbatim}
constexpr subrange& advance(iter_difference_t<I> n);
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{enumerate}
  \item If `StoreSize` is true,
    \begin{verbatim}
        auto d = n - ranges::advance(begin_, n, end_);
        if (d >= 0)
            size_ -= to_unsigned_like(d);
        else
            size_ += to_unsigned_like(-d);
        return *this;
    \end{verbatim}
  \item Otherwise,
\end{enumerate}
ranges::advance(begin_, n, end_);
return *this;

```cpp
template<size_t N, class I, class S, subrange_kind K>
requires (N < 2)
constexpr auto get(const subrange<I, S, K>& r);
```

```cpp
template<size_t N, class I, class S, subrange_kind K>
requires (N < 2)
constexpr auto get(subrange<I, S, K>&& r);
```

10 **Effects:** Equivalent to:

```cpp
if constexpr (N == 0)
  return r.begin();
else
  return r.end();
```

### 24.5.4 Dangling iterator handling

The tag type `dangling` is used together with the template aliases `borrowed_iterator_t` and `borrowed_subrange_t` to indicate that an algorithm that typically returns an iterator into or subrange of a range argument does not return an iterator or subrange which could potentially reference a range whose lifetime has ended for a particular rvalue range argument which does not model `borrowed_range` (24.4.2).

```cpp
namespace std::ranges {
  struct dangling {
    constexpr dangling() noexcept = default;
    template<class... Args>
    constexpr dangling(Args&&...) noexcept { }
  }
}
```

2 **Example:**

```cpp
vector<int> f();
auto result1 = ranges::find(f(), 42); // #1
static_assert(same_as< decltype(result1), ranges::dangling> );
auto vec = f();
auto result2 = ranges::find(vec, 42); // #2
static_assert(same_as< decltype(result2), vector<int>::iterator> );
auto result3 = ranges::find(subrange{vec}, 42); // #3
static_assert(same_as< decltype(result3), vector<int>::iterator> );
```

The call to `ranges::find` at #1 returns `ranges::dangling` since `f()` is an rvalue vector; the vector could potentially be destroyed before a returned iterator is dereferenced. However, the calls at #2 and #3 both return iterators since the lvalue `vec` and specializations of `subrange` model `borrowed_range`. — *end example*

### 24.6 Range factories

1 This subclause defines *range factories*, which are utilities to create a view.

2 Range factories are declared in namespace `std::ranges::views`.

#### 24.6.1 Empty view

**Overview**

1 `empty_view` produces a view of no elements of a particular type.

2 **Example:**

```cpp
empty_view<int> e;
static_assert(ranges::empty(e));
static_assert(0 == e.size());
-- end example
```
24.6.1.2 Class template `empty_view`  

```cpp
namespace std::ranges {
    template<class T>
    requires is_object_v<T>
    class empty_view : public view_interface<empty_view<T>> {
        public:
            static constexpr T* begin() noexcept { return nullptr; }
            static constexpr T* end() noexcept { return nullptr; }
            static constexpr T* data() noexcept { return nullptr; }
            static constexpr size_t size() noexcept { return 0; }
            static constexpr bool empty() noexcept { return true; }
    }
}
```

24.6.2 Single view  
24.6.2.1 Overview

`singlen_view` produces a view that contains exactly one element of a specified value.

The name views::single denotes a customization point object (16.4.2.2.6). Given a subexpression `E`, the expression `views::single(E)` is expression-equivalent to `single_view{E}`.

```cpp
1 single_view s{4};
for (int i : s)
    cout << i;  // prints 4
```

24.6.2.2 Class template `single_view`  

```cpp
namespace std::ranges {
    template<copy_constructible T>
    requires is_object_v<T>
    class single_view : public view_interface<single_view<T>> {
        private:
            semiregular-box<T> value_;  // exposition only (see 24.7.2)
        public:
            single_view() = default;
            constexpr explicit single_view(const T& t);
            constexpr explicit single_view(T&& t);
            template<class... Args>
            requires constructible_from<T, Args...>
            constexpr single_view(in_place_t, Args&&... args);
            constexpr T* begin() noexcept;
            constexpr const T* begin() const noexcept;
            constexpr T* end() noexcept;
            constexpr const T* end() const noexcept;
            static constexpr size_t size() noexcept;
            constexpr T* data() noexcept;
            constexpr const T* data() const noexcept;
    }
}
```

1 Effects: Initializes `value_` with `t`.

2 Effects: Initializes `value_` with `std::move(t)`.

3 Effects: Initializes `value_` as if by `value_(in_place, std::forward<Args>(args)...)`.

§ 24.6.2.2 955
constexpr T* begin() noexcept;
constexpr const T* begin() const noexcept;

Effects: Equivalent to: return data();

constexpr T* end() noexcept;
constexpr const T* end() const noexcept;

Effects: Equivalent to: return data() + 1;

static constexpr size_t size() noexcept;

Effects: Equivalent to: return 1;

constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

Effects: Equivalent to: return value_.operator->();

24.6.3 Iota view

24.6.3.1 Overview

iota_view generates a sequence of elements by repeatedly incrementing an initial value.

The name views::iota denotes a customization point object (16.4.2.2.6). Given subexpressions E and F, the expressions views::iota(E) and views::iota(E, F) are expression-equivalent to iota_view(E) and iota_view(E, F), respectively.

[Example:

```c++
for (int i : iota_view{1, 10})
    cout << i << ' '; // prints: 1 2 3 4 5 6 7 8 9
```

− end example]

24.6.3.2 Class template iota_view

namespace std::ranges {

    template<class I>
    concept decrementable = // exposition only
        see below;

    template<class I>
    concept advanceable = // exposition only
        see below;

    template<weakly_incrementable W, semiregular Bound = unreachable_sentinel_t>
    requires weakly-equality-comparable-with<W, Bound> && semiregular<W>
    class iota_view : public view_interface<iota_view<W, Bound>> {

    private:
        // 24.6.3.3, class iota_view::iterator
        struct iterator;
        // exposition only

        // 24.6.3.4, class iota_view::sentinel
        struct sentinel;
        // exposition only

        W value_ = W();    // exposition only
        Bound bound_ = Bound();    // exposition only

        public:

        iota_view() = default;
        constexpr explicit iota_view(W value);
        constexpr iota_view(type_identity_t<W> value,
            type_identity_t<Bound> bound);
        constexpr iota_view(iterator first, sentinel last) : iota_view(*first, last, bound_)
            {};

        constexpr iterator begin() const;
        constexpr auto end() const;
        constexpr iterator end() const requires same_as<W, Bound>;

        constexpr auto size() const requires see below;
    };

§ 24.6.3.2
template<class W, class Bound>
requires (!is-integer-like<W> || !is-integer-like<Bound> ||
(is-signed-integer-like<W> == is-signed-integer-like<Bound>))
    iota_view(W, Bound) -> iota_view<W, Bound>;
}

1 Let \( IOTA\)-DIFF-T(\( W \)) be defined as follows:

\( IOTA\)-DIFF-T(\( W \)) is:

\( \text{(1.1)} \)
- If \( W \) is not an integral type, or if it is an integral type and \text{sizeof(\text{iter_difference_t}<W>) \text{ is}}\) greater than \text{sizeof(\( W \))}, then \( IOTA\)-DIFF-T(\( W \)) denotes \text{iter_difference_t}<W>.

\( \text{(1.2)} \)
- Otherwise, \( IOTA\)-DIFF-T(\( W \)) is a signed integer type of width greater than the width of \( W \) if such a type exists.

\( \text{(1.3)} \)
- Otherwise, \( IOTA\)-DIFF-T(\( W \)) is an unspecified signed-integer-like type (23.3.4.4) of width not less than the width of \( W \). [Note: It is unspecified whether this type satisfies weakly_incrementable. — end note]

2 The exposition-only \text{decrementable} concept is equivalent to:

\text{template<class I>
concept decrementable =
  incrementable<I> \&\& requires(I i) {
    { --i } -> same_as<I&>;
    { 1-- } -> same_as<I>;
  };
}

3 When an object is in the domain of both pre- and post-decrement, the object is said to be \text{decrementable}.

4 Let \( a \) and \( b \) be equal objects of type \( I \). \( I \) models \text{decrementable} only if

\( \text{(4.1)} \)
- If \( a \) and \( b \) are decrementable, then the following are all true:

\( \text{(4.1.1)} \)
- \text{addressof(--a) == addressof(a)}

\( \text{(4.1.2)} \)
- \text{bool(a-- == b)}

\( \text{(4.1.3)} \)
- \text{bool(((void)a--, a) == --b)}

\( \text{(4.1.4)} \)
- \text{bool(++(--a) == b)}.

\( \text{(4.2)} \)
- If \( a \) and \( b \) are incrementable, then \text{bool(--[++a] == b)}.

5 The exposition-only \text{advanceable} concept is equivalent to:

\text{template<class I>
concept advanceable =
  decrementable<I> \&\& totally_ordered<I> \&\&
  requires(I i, const I j, const IOTA\)-DIFF-T(I) n) {
    { i += n } -> same_as<I&>;
    { i -= n } -> same_as<I>;
    I(j + n);
    I(n + j);
    I(j - n);
    { j - j } -> convertible_to<IOTA\)-DIFF-T(I)>;
  };
}

Let \( D \) be \( IOTA\)-DIFF-T(\( I \)). Let \( a \) and \( b \) be objects of type \( I \) such that \( b \) is reachable from \( a \) after \( n \) applications of ++\( a \), for some value \( n \) of type \( D \). \( I \) models \text{advanceable} only if

\( \text{(5.1)} \)
- \( (a += n) \) is equal to \( b \).

\( \text{(5.2)} \)
- \text{addressof(a += n) is equal to addressof(a)}.

\( \text{(5.3)} \)
- \text{I(a + n) is equal to (a += n)}.

\( \text{(5.4)} \)
- For any two positive values \( x \) and \( y \) of type \( D \), if \( I(a + D(x + y)) \) is well-defined, then \( I(a + D(x + y)) \) is equal to \( I(I(a + x) + y) \).

\( \text{(5.5)} \)
- \( I(a + D(0)) \) is equal to \( a \).

\( \text{(5.6)} \)
- If \( I(a + D(n - 1)) \) is well-defined, then \( I(a + n) \) is equal to \( I(I c) \{ \text{return ++c;} \}(I(a + D(n - 1))) \).

\( \text{(5.7)} \)
- \( (b += -n) \) is equal to \( a \).

\( \text{(5.8)} \)
- \( (b -= n) \) is equal to \( a \).
addressof(b -= n) is equal to addressof(b).

I(b - n) is equal to (b -= n).

D(b - a) is equal to I(n).

D(a - b) is equal to D(-n).

bool(a <= b) is true.

constexpr explicit iota_view(W value);

Preconditions: Bound denotes unreachable_sentinel_t or Bound() is reachable from value.

Effects: Initializes value_ with value.

costexpr iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);

Preconditions: Bound denotes unreachable_sentinel_t or bound is reachable from value. When W and Bound model totally_ordered_with, then bool(value <= bound) is true.

Effects: Initializes value_ with value and bound_ with bound.

costexpr iterator begin() const;

Effects: Equivalent to: return iterator{value_};

costexpr auto end() const;

Effects: Equivalent to:
if constexpr (same_as<Bound, unreachable_sentinel_t>)
return unreachable_sentinel;
else
return sentinel{bound_};

costexpr iterator end() const requires same_as<W, Bound>;

Effects: Equivalent to: return iterator{bound_};

costexpr auto size() const requires see below;

Effects: Equivalent to:
if constexpr (is-integer-like<W> && is-integer-like<Bound>)
return (value_ < 0)
? ((bound_ < 0)
? to-unsigned-like(-value_) - to-unsigned-like(-bound_)
: to-unsigned-like(bound_) + to-unsigned-like(-value_))
: to-unsigned-like(bound_) - to-unsigned-like(value_);
else
return to-unsigned-like(bound_ - value_);

Remarks: The expression in the requires-clause is equivalent to:
(same_as<W, Bound> && advanceable<W>) || (integral<W> && integral<Bound>) || sized_sentinel_for<Bound, W>

§ 24.6.3.3 Class iota_view::iterator
constexpr W operator*() const noexcept(is_nothrow_copy_constructible_v<W>);
constexpr iterator & operator++();
constexpr void operator++(int);
constexpr iterator operator++(int) requires decreamentable<W>;
constexpr iterator operator--() requires decreamentable<W>;
constexpr iterator operator--(int) requires decreamentable<W>;
constexpr iterator & operator+=(difference_type n) requires advanceable<W>;
constexpr iterator & operator-=(difference_type n) requires advanceable<W>;
constexpr W operator[](difference_type n) const requires advanceable<W>;
friend constexpr bool operator==(const iterator & x, const iterator & y) requires equality_comparable<W>;
friend constexpr bool operator<(const iterator & x, const iterator & y) requires totally_ordered<W>;
friend constexpr bool operator>(const iterator & x, const iterator & y) requires totally_ordered<W>;
friend constexpr bool operator<=(const iterator & x, const iterator & y) requires totally_ordered<W>;
friend constexpr bool operator>=(const iterator & x, const iterator & y) requires totally_ordered<W>;
friend constexpr auto operator<=>(const iterator & x, const iterator & y) requires totally_ordered<W> && three_way_comparable<W>;

Effects: Equivalent to:
--value_;
return *this;

constexpr iterator operator--(int) requires decrementable<W>;

Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr iterator& operator+=(difference_type n) requires advanceable<W>;

Effects: Equivalent to:
if constexpr (is-integer-like<W> && !is-signed-integer-like<W>) {
  if (n >= difference_type(0))
    value_ += static_cast<W>(n);
  else
    value_ -= static_cast<W>(-n);
} else {
  value_ += n;
}
return *this;

constexpr iterator& operator-=(difference_type n) requires advanceable<W>;

Effects: Equivalent to:
if constexpr (is-integer-like<W> && !is-signed-integer-like<W>) {
  if (n >= difference_type(0))
    value_ -= static_cast<W>(n);
  else
    value_ += static_cast<W>(-n);
} else {
  value_ -= n;
}
return *this;

constexpr W operator[](difference_type n) const requires advanceable<W>;

Effects: Equivalent to: return W(value_ + n);

friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<W>;

Effects: Equivalent to: return x.value_ == y.value_;

friend constexpr bool operator<(const iterator& x, const iterator& y) requires totally_ordered<W>;

Effects: Equivalent to: return x.value_ < y.value_;
friend constexpr bool operator>(const iterator& x, const iterator& y) requires totally_ordered<W>;

   Effects: Equivalent to: return y < x;

friend constexpr bool operator<=(const iterator& x, const iterator& y) requires totally_ordered<W>;

   Effects: Equivalent to: return !(y < x);

friend constexpr bool operator>=(const iterator& x, const iterator& y) requires totally_ordered<W>;

   Effects: Equivalent to: return !(x < y);

friend constexpr auto operator<=>(const iterator& x, const iterator& y) requires totally_ordered<W> && three_way_comparable<W>;

   Effects: Equivalent to: return x.value_ <=> y.value_;

friend constexpr iterator operator+(iterator i, difference_type n) requires advanceable<W>;

   Effects: Equivalent to: return i += n;

friend constexpr iterator operator+(difference_type n, iterator i) requires advanceable<W>;

   Effects: Equivalent to: return i + n;

friend constexpr iterator operator-(iterator i, difference_type n) requires advanceable<W>;

   Effects: Equivalent to: return i -= n;

friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires advanceable<W>;

   Effects: Equivalent to:

   using D = difference_type;
   if constexpr (is_integer_like<W>) {
      if constexpr (is_signed_integer_like<W>)
         return D(D(x.value_) - D(y.value_));
      else
         return (y.value_ > x.value_)
            ? D(-D(y.value_ - x.value_))
            : D(x.value_ - y.value_);
   } else {
      return x.value_ - y.value_;
   }

24.6.3.4 Class iota_view::sentinel [range.iota.sentinel]

namespace std::ranges {
   template<weakly_incrementable W, semiregular Bound>
   requires weakly-equality-comparable-with<W, Bound>
   struct iota_view<W, Bound>::sentinel {
      private:
         Bound bound_ = Bound(); // exposition only
	public:
         sentinel() = default;
         constexpr explicit sentinel(Bound bound);

         friend constexpr bool operator==(const iterator& x, const sentinel& y);

         friend constexpr iterator operator-(const iterator& x, const sentinel& y) requires sized_sentinel_for<Bound, W>;

         friend constexpr iterator operator-(const sentinel& x, const iterator& y) requires sized_sentinel_for<Bound, W>;

§ 24.6.3.4
constexpr explicit sentinel(Bound bound);

Effects: Initializes bound_ with bound.

friend constexpr bool operator==(const iterator& x, const sentinel& y);

Effects: Equivalent to: return x.value_ == y.bound_

friend constexpr iter_difference_t<W> operator-(const iterator& x, const sentinel& y)
requires sized_sentinel_for<Bound, W>;

Effects: Equivalent to: return x.value_ - y.bound_

friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
requires sized_sentinel_for<Bound, W>;

Effects: Equivalent to: return -(y - x);

24.6.4 Istream view [range.istream]

24.6.4.1 Overview [range.istream.overview]

basic_istream_view models input_range and reads (using operator>>) successive elements from its corresponding input stream.

[Example:
auto ints = istringstream("0 1 2 3 4");
ranges::copy(istream_view<int>(ints), ostream_iterator<int>{cout, "-"));
// prints 0-1-2-3-4-
— end example]

24.6.4.2 Class template basic_istream_view [range.istream.view]

namespace std::ranges {
    template<class Val, class CharT, class Traits>
    concept stream_extractable = // exposition only
        requires(basic_istream<CharT, Traits>& is, Val& t) {
            is >> t;
        };

    template<movable Val, class CharT, class Traits>
    requires default_initializable<Val> &&
        stream_extractable<Val, CharT, Traits>
    class basic_istream_view : public view_interface<basic_istream_view<Val, CharT, Traits>> {
        public:
            basic_istream_view() = default;
            constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);

            constexpr auto begin() {
                if (stream_) {
                    *stream_ >> object_
                }
                return iterator{*this};
            }

            constexpr default_sentinel_t end() const noexcept;

            private:
                struct iterator; // exposition only
                basic_istream<CharT, Traits>* stream_ = nullptr; // exposition only
                Val object_ = Val(); // exposition only
            };

§ 24.6.4.2
constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);

Effects: Initializes stream_ with addressof(stream).

constexpr default_sentinel_t end() const noexcept;

Effects: Equivalent to: return default_sentinel;

template<class Val, class CharT, class Traits>
basic_istream_view<Val, CharT, Traits> istream_view(basic_istream<CharT, Traits>& s);

Effects: Equivalent to: return basic_istream_view<Val, CharT, Traits>{s};

### 24.6.4.3 Class template basic_istream_view::iterator

namespace std::ranges {

template<movable Val, class CharT, class Traits>
requires default_initializable<Val> &&
stream-extractable<Val, CharT, Traits>
class basic_istream_view<Val, CharT, Traits>::iterator {
   // exposition only
   public:
      using iterator_concept = input_iterator_tag;
      using difference_type = ptrdiff_t;
      using value_type = Val;

      iterator() = default;
      constexpr explicit iterator(basic_istream_view& parent) noexcept;
      iterator(const iterator&) = delete;
      iterator(iterator&&) = default;

      iterator& operator=(const iterator&) = delete;
      iterator& operator=(iterator&&) = default;

      iterator& operator++();
      void operator++(int);

      Val& operator*() const;

      friend bool operator==(const iterator& x, default_sentinel_t);

   private:
      basic_istream_view* parent_ = nullptr;
   } // exposition only

}

constexpr explicit iterator(basic_istream_view& parent) noexcept;

Effects: Initializes parent_ with addressof(parent).

iterator& operator++();

Preconditions: parent_->stream_ != nullptr is true.

Effects: Equivalent to:
   *parent_->stream_ >> parent_->object_;
   return *this;

void operator++(int);

Preconditions: parent_->stream_ != nullptr is true.

Effects: Equivalent to ++this.

Val& operator*() const;

Preconditions: parent_->stream_ != nullptr is true.

Effects: Equivalent to: return parent_->object_;

§ 24.6.4.3
friend bool operator==(const iterator& x, default_sentinel_t);

Effects: Equivalent to: return x.parent_ == nullptr || !x.parent_—stream;

24.7 Range adaptors

This subclause defines range adaptors, which are utilities that transform a range into a view with custom behaviors. These adaptors can be chained to create pipelines of range transformations that evaluate lazily as the resulting view is iterated.

Range adaptors are declared in namespace std::ranges::views.

The bitwise OR operator is overloaded for the purpose of creating adaptor chain pipelines. The adaptors also support function call syntax with equivalent semantics.

[Example:

```cpp
vector<int> ints{0,1,2,3,4,5};
auto even = [](int i){ return 0 == i % 2; };
auto square = [](int i) { return i * i; };
for (int i : ints | views::filter(even) | views::transform(square)) {
    cout << i << ' ';
} // prints: 0 4 16
assert(ranges::equal(ints | views::filter(even), views::filter(ints, even)));
— end example]

24.7.1 Range adaptor objects

A range adaptor closure object is a unary function object that accepts a viewable_range argument and returns a view. For a range adaptor closure object C and an expression R such that decltype((R)) models viewable_range, the following expressions are equivalent and yield a view:

```cpp
C(R)
R | C
```

Given an additional range adaptor closure object D, the expression C | D is well-formed and produces another range adaptor closure object such that the following two expressions are equivalent:

```cpp
R | C | D
R | (C | D)
```

A range adaptor object is a customization point object (16.4.2.2.6) that accepts a viewable_range as its first argument and returns a view.

If a range adaptor object accepts only one argument, then it is a range adaptor closure object.

If a range adaptor object accepts more than one argument, then the following expressions are equivalent:

```cpp
adaptor(range, args...)
adaptor(args...)(range)
range | adaptor(args...)
```

In this case, adaptor(args...) is a range adaptor closure object.

24.7.2 Semiregular wrapper

Many types in this subclause are specified in terms of an exposition-only class template semiregular-box. semiregular-box<T> behaves exactly like optional<T> with the following differences:

1. semiregular-box<T> constrains its type parameter T with copy_constructible<T> && is_object-v<T>.
2. If T models default_initializable, the default constructor of semiregular-box<T> is equivalent to:
   ```cpp
   constexpr semiregular-box() noexcept(is_nothrow_default_constructible_v<T>)
   { in_place }
   ```
3. If assignable_from<T&>, const T& is not modeled, the copy assignment operator is equivalent to:
   ```cpp
   semiregular-box& operator=(const semiregular-box& that)
   noexcept(is_nothrow_copy_constructible_v<T>)
   { if (that) emplace(*that); }
   ```
else reset();
  return *this;
}

— If assignable_from<T&, T> is not modeled, the move assignment operator is equivalent to:

```
semiregular-box& operator=(semiregular-box&& that)
  noexcept(is_nothrow_move_constructible_v<T>)
  {
    if (that) emplace(std::move(*that));
    else reset();
    return *this;
  }
```

### 24.7.3 All view

views::all returns a view that includes all elements of its range argument.

The name views::all denotes a range adaptor object (24.7.1). Given a subexpression $E$, the expression views::all($E$) is expression-equivalent to:

1. decay-copy($E$) if the decayed type of $E$ models view.
2. Otherwise, ref_view($E$) if that expression is well-formed.
3. Otherwise, subrange($E$).

#### 24.7.3.1 Class template ref_view

`ref_view` is a view of the elements of some other range.

```
namespace std::ranges {
  template<range R>
  requires is_object_v<R>
  class ref_view : public view_interface<ref_view<R>> {
    private:
      R* r_ = nullptr; // exposition only
    public:
      constexpr ref_view() noexcept = default;
    
    template<not_same_as<ref_view> T>
    requires see below
    constexpr ref_view(T&& t);
    
    constexpr R& base() const { return *r_; }
    
    constexpr iterator_t<R> begin() const { return ranges::begin(*r_); }
    constexpr sentinel_t<R> end() const { return ranges::end(*r_); }
    
    constexpr bool empty() const
      requires requires { ranges::empty(*r_); }
    { return ranges::empty(*r_); }
    
    constexpr auto size() const requires sized_range<R>
      requires requires { ranges::size(*r_); }
    { return ranges::size(*r_); }
    
    constexpr auto data() const requires contiguous_range<R>
      requires requires { ranges::data(*r_); }
    { return ranges::data(*r_); }
  };

  template<class R>
  ref_view(R&) -> ref_view<R>;
}
```

### 2

Effects: Initializes $r_\_\_$ with addressof(static_cast<R&>(std::forward<T>(t))).

### 3

Remarks: Let `FUN` denote the exposition-only functions.
void FUN(R&);
void FUN(R&&) = delete;

The expression in the requires-clause is equivalent to:
convertible_to<T, R&> && requires {
  FUN(declval<T>()); }

24.7.4 Filter view

24.7.4.1 Overview

filter_view presents a view of the elements of an underlying sequence that satisfy a predicate.

The name views::filter denotes a range adaptor object (24.7.1). Given subexpressions E and P, the expression views::filter(E, P) is expression-equivalent to filter_view{E, P}.

[Example:

vector<int> is{ 0, 1, 2, 3, 4, 5, 6 };
filter_view evens(is, [](int i) { return 0 == i % 2; });
for (int i : evens)
  cout << i << ' '; // prints: 0 2 4 6
— end example]

24.7.4.2 Class template filter_view

namespace std::ranges {
  template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
  requires view<V> && is_object_v<Pred>
  class filter_view : public view_interface<filter_view<V, Pred>> {
    private:
      V base_ = V(); // exposition only
      semiregular-box<Pred> pred_; // exposition only

      // 24.7.4.3, class filter_view::iterator
    class iterator;
    // exposition only

    // 24.7.4.4, class filter_view::sentinel
    class sentinel;
    // exposition only

    public:
      filter_view() = default;
      constexpr filter_view(V base, Pred pred);
      constexpr V base() const& requires copy_constructible<V> { return base_; }
      constexpr V base() && { return std::move(base_); }
      constexpr const Pred& pred() const;
      constexpr iterator begin();
      constexpr auto end() {
        if constexpr (common_range<V>)
          return iterator{*this, ranges::end(base_)};
        else
          return sentinel{*this};
      }
  };

  template<class R, class Pred>
  filter_view(R&&, Pred) -> filter_view<views::all_t<R>, Pred>;
}

costexpr filter_view(V base, Pred pred);

  Effects: Initializes base_ with std::move(base) and initializes pred_ with std::move(pred).

costexpr const Pred& pred() const;

  Effects: Equivalent to: return *pred_;
```cpp
constexpr iterator begin();

// Preconditions: pred_.has_value.
Returns: {*this, ranges::find_if(base_.ref(*pred_))}.

Remarks: In order to provide the amortized constant time complexity required by the range concept when
filter_view models forward_range, this function caches the result within the filter_view for use on
subsequent calls.

24.7.4.3 Class filter_view::iterator

namespace std::ranges {
    template<input_range V, indirect Unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class filter_view<V, Pred>::iterator {
        private:
            iterator_t<V> current_ = iterator_t<V>(); // exposition only
            filter_view* parent_ = nullptr; // exposition only
        public:
            using iterator_concept = see below;
            using iterator_category = see below;
            using value_type = range_value_t<V>;
            using difference_type = range_difference_t<V>;

            iterator() = default;
            constexpr iterator(filter_view& parent, iterator_t<V> current);

            constexpr iterator_t<V> base() const &
                requires copyable<iterator_t<V>>;
            constexpr iterator_t<V> base() &&;
            constexpr range_reference_t<V> operator*() const;
            constexpr iterator_t<V> operator->() const
                requires has_arrow<iterator_t<V>> && copyable<iterator_t<V>>;

            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator operator++(int) requires forward_range<V>;

            constexpr iterator& operator--();
            constexpr iterator operator--(int) requires bidirectional_range<V>;

            friend constexpr bool operator==(const iterator& x, const iterator& y)
                requires equality_comparable<iterator_t<V>>;

            friend constexpr range_rvalue_reference_t<V> iter_move(const iterator& i)
                noexcept(noexcept(ranges::iter_move(i.current_.current_.current_.current_)));  
            friend constexpr void iter_swap(const iterator& x, const iterator& y)
                noexcept(noexcept(ranges::iter_swap(x.current_.current_.current_.current_, y.current_.current_.current_.current_.current_.current_.current_.current_)))
                requires indirectly_swappable<iterator_t<V>>;
    };
}

1 Modification of the element a filter_view::iterator denotes is permitted, but results in undefined behavior if
the resulting value does not satisfy the filter predicate.

2 iterator::iterator_concept is defined as follows:

(2.1) — If V models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
(2.2) — Otherwise, if V models forward_range, then iterator_concept denotes forward_iterator_tag.
(2.3) — Otherwise, iterator_concept denotes input_iterator_tag.

3 iterator::iterator_category is defined as follows:

(3.1) — Let C denote the type iterator traits<iterator_t<V>>::iterator_category.
(3.2) — If C models derived_from<bidirectional_iterator_tag>, then iterator_category denotes bidirectional_iterator_tag.
```
— Otherwise, if \( C \) models derived_from<\forward_iterator_tag>, then \( \text{iterator_category} \) denotes \forward_iterator_tag.

— Otherwise, \( \text{iterator_category} \) denotes \( C \).

\[
\text{constexpr iterator} (\text{filter_view} \& \text{parent}, \text{iterator_t<V> current});
\]

\( \text{Effects:} \) Initializes \text{current} with std::move(current) and \text{parent} with addressof(parent).

\[

friend constexpr void iter_swap(const iterator& x, const iterator& y)
  noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))
  requires indirectly_swappable<iterator_t<V>>;

  Effects: Equivalent to ranges::iter_swap(x.current_, y.current_).

24.7.4.4 Class filter_view::sentinel

namespace std::ranges {
  template<input_range V, indirect unary predicate<iterator_t<V>> Pred>
  requires view<V> & is object_v<Pred>
  class filter_view<V, Pred>::sentinel {
    private:
      sentinel_t<V> end_ = sentinel_t<V>(); // exposition only
    public:
      sentinel() = default;
      constexpr explicit sentinel(filter_view& parent);
      constexpr sentinel_t<V> base() const;
      friend constexpr bool operator==(const iterator& x, const sentinel& y);
    }
  }

constexpr explicit sentinel(filter_view& parent);

  Effects: Initializes end_ with ranges::end(parent.base_).

constexpr sentinel_t<V> base() const;

  Effects: Equivalent to: return end_;

friend constexpr bool operator==(const iterator& x, const sentinel& y);

  Effects: Equivalent to: return x.current_ == y.end_;

24.7.5 Transform view

24.7.5.1 Overview

transform_view presents a view of an underlying sequence after applying a
transformation function to each element.

The name views::transform denotes a range adaptor object (24.7.1). Given
subexpressions E and F, the expression views::transform(E, F) is
expression-equivalent to transform_view{E, F}.

[Example:
  vector<int> is{ 0, 1, 2, 3, 4 };
  transform_view squares{is, [](int i) { return i * i; }};
  for (int i : squares)
    cout << i << ' '; // prints: 0 1 4 9 16
  — end example]

24.7.5.2 Class template transform_view

namespace std::ranges {
  template<input_range V, copy constructible F>
  requires view<V> & is object_v<F> &&
  regular invocable<F&, range reference_t<V>> &&
  can reference<invoke result_t<F&, range reference_t<V>>>;
  class transform_view : public view interface<transform view>V, F>
  {
    private:
      // 24.7.5.3 class template transform view:: iterator
      template<bool> struct iterator;
  } // exposition only

  template<bool> struct sentinel;

  template<bool> struct sentinel;

  V base_ = V(); // exposition only
  semiregular box<F> fun_; // exposition only

§ 24.7.5.2 969
public:
  transform_view() = default;
  constexpr transform_view(V base, F fun);

  constexpr V base() const
      requires copy_constructible<V> { return base_; }

  constexpr V base() && { return std::move(base_); }

  constexpr iterator<false> begin();
  constexpr iterator<true> begin() const
      requires range<const V> &&
      regular_invocable<const F&, range_reference_t<const V>>;

  constexpr iterator<false> end();
  constexpr iterator<true> end() const
      requires range<const V> &&
      regular_invocable<const F&, range_reference_t<const V>>;

  constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
  constexpr auto size() const requires sized_range<const V>
      { return ranges::size(base_); }
};

template<class R, class F>
  transform_view(R&&, F) -> transform_view<views::all_t<R>, F>;

24.7.6 Take view

24.7.6.1 Overview

take_view produces a view of the first \( N \) elements from another view, or all the elements if the adapted view contains fewer than \( N \).

The name views::take denotes a range adaptor object (24.7.1). Let \( E \) and \( F \) be expressions, let \( T \) be remove_cvref_t<decltype((E))>, and let \( D \) be range_difference_t<decltype((E))>. If decltype((F)) does not model convertible_to<O>, views::take(E, F) is ill-formed. Otherwise, the expression views::take(E, F) is expression-equivalent to:

24.7.6.2 Class template take_view

namespace std::ranges {

template<typename V>
class take_view : public view_interface<take_view<V>> {
private:
  V base_ = V(); // exposition only
  range_difference_t<V> count_ = 0; // exposition only
  // 24.7.6.3, class template take_view::sentinel
  template<typename> struct sentinel; // exposition only
public:
  take_view() = default;
  constexpr take_view(V base, range_difference_t<V> count); // 24.7.6.2

  constexpr V base() const
  requires copy_constructible<V> { return base_; } // 24.7.6.2
  constexpr V base() && { return std::move(base_); } // 24.7.6.2
}

§ 24.7.6.2
constexpr auto begin() requires (!\texttt{simple-view}<V>) {
    if constexpr (sized_range<V>) {
        if constexpr (random_access_range<V>)
            return ranges::begin(base_);
        else {
            auto sz = size();
            return counted_iterator(ranges::begin(base_), sz);
        }
    } else
        return counted_iterator(ranges::begin(base_), count_);
}

constexpr auto begin() const requires range<const V> {
    if constexpr (sized_range<const V>) {
        if constexpr (random_access_range<const V>)
            return ranges::begin(base_);
        else {
            auto sz = size();
            return counted_iterator(ranges::begin(base_), sz);
        }
    } else
        return counted_iterator(ranges::begin(base_), count_);
}

constexpr auto end() requires (!\texttt{simple-view}<V>) {
    if constexpr (sized_range<V>) {
        if constexpr (random_access_range<V>)
            return ranges::begin(base_) + size();
        else
            return default_sentinel;
    } else
        return sentinel<false>{ranges::end(base_)};
}

constexpr auto end() const requires range<const V> {
    if constexpr (sized_range<const V>) {
        if constexpr (random_access_range<const V>)
            return ranges::begin(base_) + size();
        else
            return default_sentinel;
    } else
        return sentinel<true>{ranges::end(base_)};
}

constexpr auto size() requires sized_range<V> {
    auto n = ranges::size(base_);
    return ranges::min(n, static_cast<decltype(n)>)(count_);
}

constexpr auto size() const requires sized_range<const V> {
    auto n = ranges::size(base_);
    return ranges::min(n, static_cast<decltype(n)>)(count_);
};

template<range R>
take_view(R&, range_difference_t<R>)
    -> take_view<views::all_t<R>>;

constexpr take_view(V base, range_difference_t<V> count);

\textit{Effects:} Initializes $\texttt{base}$ with $\texttt{std::move(base)}$ and $\texttt{count}$ with $\texttt{count}$. 
24.7.6.3 Class template `take_view::sentinel`  

namespace std::ranges {
    template<view V>
    template<bool Const>
    class take_view<V>::sentinel {
    private:
        using Base = conditional_t<Const, const V, V>;  // exposition only
        using CI = counted_iterator<iterator_t<Base>>;    // exposition only
        sentinel_t<Base> end_ = sentinel_t<Base>();      // exposition only
    public:

            requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
        constexpr sentinel_t<Base> base() const;
        friend constexpr bool operator==(const CI & y, const sentinel & x);
    }
}

constexpr explicit sentinel(sentinel_t<Base> end);  

Effects: Initializes `end_` with `end`.

constexpr sentinel(sentinel<!Const> s)          
    requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

Effects: Initializes `end_` with `std::move(s.end_)`.

constexpr sentinel_t<Base> base() const;

Effects: Equivalent to: `return end_`;

friend constexpr bool operator==(const CI & y, const sentinel & x);

Effects: Equivalent to: `return y.count() == 0 || y.base() == x.end_`;

24.7.7 Take while view  

24.7.7.1 Overview  

Given a unary predicate `pred` and a `view r`, `take_while_view` produces a view of the range `[begin(r), ranges::find_if_not(r, pred))].` The name `views::take_while` denotes a range adaptor object (24.7.1). Given subexpressions `E` and `F`, the expression `views::take_while(E, F)` is expression-equivalent to `take_while_view{E, F}`.

[Example:  
  auto input = istreamstream("
1 2 3 4 5 6 7 8 9");  
  auto small = [i](const auto x) noexcept { return x < 5; };  
  auto small_ints = istream_view<int>(input) | views::take_while(small);  
  for (const auto i : small_ints) {
    cout << i << ' ';  // prints 0 1 2 3 4
  }
  auto i = 0;
  input >> i;
  cout << i;  // prints 6  
— end example]

24.7.7.2 Class template `take_while_view`  

namespace std::ranges {
    template<view V, class Pred>
        requires input_range<V> && is_object_v<Pred> &&
        indirect_unary_predicate<const Pred, iterator_t<V>>
    class take_while_view : public view_interface<take_while_view<V, Pred>> {
        // 24.7.7.3 class template `take_while_view::sentinel`
        template<bool> class sentinel;  // exposition only
namespace std::ranges {

    template<class R, class Pred>
    take_while_view(R&&, Pred) -> take_while_view<views::all_t<R>, Pred>;

}  // namespace std::ranges

§ 24.7.7.3 Class template take_while_view::sentinel

namespace std::ranges {

    constexpr auto end() const requires range<const V>
    { return sentinel<true>(ranges::end(base_), addressof(*pred_)); }

};

template<class R, class Pred>
take_while_view(R&&, Pred) -> take_while_view<views::all_t<R>, Pred>;

}  // namespace std::ranges

V base() && { return std::move(base_); }
constexpr sentinel(sentinel<!Const> s)
    requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;  

friend constexpr bool operator==(const iterator_t<Base>& x, const sentinel& y);  

Effects: Equivalent to: return y.end_ == x || !invoke(*y.pred_, *x);

24.7.8 Drop view

24.7.8.1 Overview

drop_view produces a view excluding the first $N$ elements from another view, or an empty range if the adapted view contains fewer than $N$ elements.

The name views::drop denotes a range adaptor object (24.7.1). Let $E$ and $F$ be expressions, let $T$ be remove_cvref_t<decay_t<$E$>>, and let $D$ be range_difference_t<decay_t<$E$>>. If decay_t($F$) does not model convertible_to<$D$>, views::drop($E$, $F$) is ill-formed. Otherwise, the expression views::drop($E$, $F$) is expression-equivalent to:

(2.1) — If $T$ is a specialization of ranges::empty_view (24.6.1.2), then ((void) $F$, decay-copy($E$)).

(2.2) — Otherwise, if $T$ models random_access_range and sized_range and is

(2.2.1) — a specialization of span (22.7.3) where $T$::extent == dynamic_extent,

(2.2.2) — a specialization of basic_string_view (21.4),

(2.2.3) — a specialization of ranges::iota_view (24.6.3.2), or

(2.2.4) — a specialization of ranges::subrange (24.5.3),

then $T$::begin($E$) + min<$D$>(ranges::size($E$), $F$), ranges::end($E$), except that $E$ is evaluated only once.

(2.3) — Otherwise, ranges::drop_view($E$, $F$).

3 [Example:

```cpp
auto ints = views::iota(0) | views::take(10);
auto latter_half = drop_view<ints, 5>;
for (auto i : latter_half) {
    cout << i << ' ';
} // prints 5 6 7 8 9
```

— end example]

24.7.8.2 Class template drop_view

namespace std::ranges {

template_view V>

class drop_view : public view_interface<drop_view<V>> { public:

    drop_view() = default;
    constexpr drop_view(V base, range_difference_t<$V$> count);

    constexpr V base() const requires copy_constructible<$V$> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr auto begin()
        requires (!($V$ && random_access_range<$V$>));
    constexpr auto begin() const
        requires random_access_range<const $V$>;

    constexpr auto end()
        requires (!simple_view<$V$>)
        { return ranges::end(base_); }
    constexpr auto end() const
        requires range<const $V$>
        { return ranges::end(base_); }

§ 24.7.8.2
constexpr auto size()
    requires sized_range<V>
{
    const auto s = ranges::size(base_);
    const auto c = static_cast<decltype(s)>(count_);
    return s < c ? 0 : s - c;
}

constexpr auto size() const
    requires sized_range<const V>
{
    const auto s = ranges::size(base_);
    const auto c = static_cast<decltype(s)>(count_);
    return s < c ? 0 : s - c;
}

private:
    V base_ = V(); // exposition only
    range_difference_t<V> count_ = 0; // exposition only
};

template<class R>
    drop_view(R&&, range_difference_t<R>) -> drop_view<views::all_t<R>>;

constexpr drop_view(V base, range_difference_t<V> count);

1 Preconditions: count >= 0 is true.
2 Effects: Initializes base_ with std::move(base) and count_ with count.

constexpr auto begin()
    requires (! (simple-view<V> && random_access_range<V>));
constexpr auto begin() const
    requires random_access_range<const V>;
3 Returns: ranges::next(ranges::begin(base_), count_, ranges::end(base_)).
4 Remarks: In order to provide the amortized constant-time complexity required by the range concept when drop_view models forward_range, the first overload caches the result within the drop_view for use on subsequent calls. [Note: Without this, applying a reverse_view over a drop_view would have quadratic iteration complexity. — end note]

24.7.9 Drop while view

24.7.9.1 Overview

1 Given a unary predicate pred and a view r, drop_while_view produces a view of the range [ranges::find_if_not(r, pred), ranges::end(r)].
2 The name views::drop_while denotes a range adaptor object (24.7.1). Given subexpressions E and F, the expression views::drop_while(E, F) is expression-equivalent to drop_while_view{E, F}.
3 [Example:
    constexpr auto source = " \t \t \t hello there";
    auto is_invisible = [] (const auto x) { return x == ' ' || x == '\t'; };
    auto skip_ws = drop_while_view<source, is_invisible>;
    for (auto c : skip_ws) {
        // prints hello there with no leading space
    }
    — end example]

24.7.9.2 Class template drop_while_view

namespace std::ranges {
    template <view V, class Pred>
        requires input_range<V> && is_object_v<Pred> &&
            indirect_unary_predicate<const Pred, iterator_t<V>>
    class drop_while_view : public view_interface<drop_while_view<V, Pred>> {

§ 24.7.9.2

980
public:
drop_while_view() = default;
constexpr drop_while_view(V base, Pred pred);

constexpr V base() const requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }

constexpr const Pred& pred() const;
constexpr auto begin();
constexpr auto end() { return ranges::end(base_); }

private:
V base_ = V(); // exposition only
semiregular-box<Pred> pred_; // exposition only

};

template<class R, class Pred>
drop_while_view(R&&, Pred) -> drop_while_view<views::all_t<R>, Pred>;

constexpr drop_while_view(V base, Pred pred);

Effects: Initializes base_ with std::move(base) and pred_ with std::move(pred).

constexpr const Pred& pred() const;

Effects: Equivalent to: return *pred_;

constexpr auto begin();

Returns: ranges::find_if_not(base_, cref(*pred_)).

Remarks: In order to provide the amortized constant-time complexity required by the range concept when
drop_while_view models forward_range, the first call caches the result within the drop_while_view for
use on subsequent calls. [Note: Without this, applying a reverse_view over a drop_while_view would have
quadratic iteration complexity. — end note]

24.7.10 Join view [range.join]
24.7.10.1 Overview [range.join.overview]
join_view flattens a view of ranges into a view.

The name views::join denotes a range adaptor object (24.7.1). Given a subexpression E, the expression views::join(E)
is expression-equivalent to join_view{E}.

[Example:

vector<string> ss{"hello", "", "world", "!"};
join_view greeting(ss);
for (char ch : greeting)
    cout << ch; // prints: hello world!

— end example]

24.7.10.2 Class template join_view [range.join.view]
namespace std::ranges {

template<input_range V>
    requires view<V> && input_range<range_reference_t<V>> &&
    (is_reference_v<range_reference_t<V>> ||
    view<range_value_t<V>>)
    class join_view : public view_interface<join_view<V>> {
        private:
            using InnerRng = // exposition only
            range_reference_t<V>;;
// 24.7.10.3, class template join_view::iterator
template<bool Const>
struct iterator; // exposition only

// 24.7.10.4, class template join_view::sentinel
template<bool Const>
struct sentinel; // exposition only

V base_ = V(); // exposition only
views::all_t<InnerRng> inner_ = // exposition only, present only when !is_reference_v<InnerRng>
views::all_t<InnerRng>();

public:
join_view() = default;
constexpr explicit join_view(V base);

constexpr V base() const& requires copy_constructible<V> { return base_; }  
constexpr V base() && { return std::move(base_); }

constexpr auto begin() {
constexpr bool use_const = simple_view<V> &&
is_reference_v<range_reference_t<V>>;
return iterator<use_const>{*this, ranges::begin(base_)};
}

constexpr auto begin() const
requires input_range<const V> &&
is_reference_v<range_reference_t<const V>> {
return iterator<true>{*this, ranges::begin(base_)};
}

constexpr auto end() {
if constexpr (forward_range<V> &&
is_reference_v<range_reference_t<const V>> && forward_range<range_reference_t<const V>> &&
common_range<V> && common_range<range_reference_t<const V>>)
return iterator<true>{*this, ranges::end(base_)};
else
return sentinel<true>{*this};
}

constexpr auto end() const
requires input_range<const V> &&
is_reference_v<range_reference_t<const V>> {
if constexpr (forward_range<const V> &&
is_reference_v<range_reference_t<const V>> && forward_range<range_reference_t<const V>> &&
common_range<const V> &&
common_range<range_reference_t<const V>>)
return iterator<true>{*this, ranges::end(base_)};
else
return sentinel<true>{*this};
}

};

template<class R>
explicit join_view(R&&) -> join_view<views::all_t<R>>;

constexpr explicit join_view(V base);

Effects: Initializes base_ with std::move(base).

24.7.10.3 Class template join_view::iterator

namespace std::ranges {
  template<input_range V>
    requires view<V> && input_range<range_reference_t<V>> &&

§ 24.7.10.3
template<
    bool Const
>
struct join_view<V>::iterator {
  private:
  using Parent = condition_t<
      Const, const join_view, join_view>;
  using Base = condition_t<
      Const, const V, V>;
  static constexpr bool ref_is_glvalue =
      is_reference_v<range_reference_t<Base>>;
  iterator_t<Base> outer_ = iterator_t<Base>();
  iterator_t<range_reference_t<Base>> inner_ =
      iterator_t<range_reference_t<Base>>();
  Parent* parent_ = nullptr;
  constexpr void satisfy();
  public:
  using iterator_concept = see below;
  using iterator_category = see below;
  using value_type = range_value_t<range_reference_t<Base>>;
  using difference_type = see below;
  iterator() = default;
  constexpr iterator(Parent& parent, iterator_t<Base> outer);
  constexpr iterator(iterator<!Const> i)
      requires Const &&
          convertible_to<iterator_t<V>, iterator_t<Base>> &&
          convertible_to<iterator_t<InnerRng>,
              iterator_t<range_reference_t<Base>>>;
  constexpr decltype(auto) operator*() const { return *inner_; }
  constexpr iterator_t<Base> operator->() const
      requires has_arrow<iterator_t<Base>> && copyable<iterator_t<Base>>;
  constexpr iterator& operator++();
  constexpr void operator++(int);
  constexpr iterator& operator++(int)
      requires ref_is_glvalue && forward_range<Base> &&
          forward_range<range_reference_t<Base>>;
  constexpr iterator& operator--();
  constexpr iterator operator--(int)
      requires ref_is_glvalue && bidirectional_range<Base> &&
          bidirectional_range<range_reference_t<Base>> &&
          common_range<range_reference_t<Base>>;
  friend constexpr bool operator==(const iterator& x, const iterator& y)
      requires ref_is_glvalue && equality_comparable<iterator_t<Base>> &&
          equality_comparable<iterator_t<range_reference_t<Base>>>;
  friend constexpr decltype(auto) iter_move(const iterator& i)
      noexcept(noexcept(ranges::iter_move(i.inner_))) {
      return ranges::iter_move(i.inner_);
  }
  friend constexpr void iter_swap(const iterator& x, const iterator& y)
      noexcept(noexcept(ranges::iter_swap(x.inner_, y.inner_)));
iterator::iterator_concept is defined as follows:

(1.1) If ref-is-glvalue is true and Base and range_reference_t<Base> each model bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.

(1.2) Otherwise, if ref-is-glvalue is true and Base and range_reference_t<Base> each model forward_range, then iterator_concept denotes forward_iterator_tag.

(1.3) Otherwise, iterator_concept denotes input_iterator_tag.

iterator::iterator_category is defined as follows:

(2.1) Let OUTER denote iterator_traits<iterator_t<Base>>::iterator_category, and let INNER denote iterator_traits<iterator_t<range_reference_t<Base>>>::iterator_category.

(2.2) If ref-is-glvalue is true and OUTER and INNER each model derived_from<bidirectional_iterator_tag>, iterator_category denotes bidirectional_iterator_tag.

(2.3) Otherwise, if ref-is-glvalue is true and OUTER and INNER each model derived_from<forward_iterator_tag>, iterator_category denotes forward_iterator_tag.

(2.4) Otherwise, if OUTER and INNER each model derived_from<input_iterator_tag>, iterator_category denotes input_iterator_tag.

(2.5) Otherwise, iterator_category denotes output_iterator_tag.

iterator::difference_type denotes the type:

```cpp
common_type_t<
    range_difference_t<Base>,
    range_difference_t<range_reference_t<Base>>
```

join_view iterators use the `satisfy` function to skip over empty inner ranges.

```cpp
constexpr void satisfy();  // exposition only
```

Effects: Equivalent to:

```cpp
auto update_inner = [this](range_reference_t<Base> x) -> auto& {
    if constexpr (ref-is-glvalue) // x is a reference
        return x;
    else
        return (parent_->inner_ = views::all(std::move(x)));
};
```

```cpp
for (; outer_ != ranges::end(parent_->base_); ++outer_) {
    auto& inner = update_inner(*outer_);
    inner_ = ranges::begin(inner);
    if (inner_ != ranges::end(inner))
        return;
}
```

```cpp
if constexpr (ref-is-glvalue)
    inner_ = iterator_t<range_reference_t<Base>>();
```

Effects: Initializes `outer_` with std::move(outer) and `parent_` with addressof(parent); then calls `satisfy()`.

```cpp
constexpr iterator(Parent& parent, iterator_t<Base> outer);
```

Effects: Initializes `outer_` with std::move(outer) and `parent_` with addressof(parent); then calls `satisfy()`.

```cpp
constexpr iterator(iterator<!Const> i)
requires Const &&
    convertible_to<iterator_t<V>, iterator_t<Base>> &&
    convertible_to<iterator_t<InnerRng>,
        iterator_t<range_reference_t<Base>>;`
```

Effects: Initializes `outer_` with std::move(i.outer_), `inner_` with std::move(i.inner_), and `parent_` with i.parent_.

§ 24.7.10.3
constexpr iterator_t<Base> operator->() const
requires has-arrow<iterator_t<Base>> && copyable<iterator_t<Base>>;

Effects: Equivalent to return inner_;
24.7.10.4 Class template `join_view::sentinel`

```cpp
namespace std::ranges {
    template<input_range V>
    requires view<V> && input_range<range_reference_t<V>> &&
    (is_reference_v<range_reference_t<V>> ||
    view<range_value_t<V>>)
    template<bool Const>
    struct join_view<V>::sentinel {
        private:
            using Parent = // exposition only
                conditional_t<Const, const join_view, join_view>;
            using Base = conditional_t<Const, const V, V>; // exposition only
            sentinel_t<Base> end_ = sentinel_t<Base>(); // exposition only
        public:
            sentinel() = default;
            constexpr explicit sentinel(Parent& parent);
            constexpr sentinel(sentinel<!Const> s) // exposition only
                requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
            friend constexpr bool operator==(const iterator<Const>& x, const sentinel& y);
        };
    }
}
```

```
constexpr explicit sentinel(Parent& parent);
Effects: Initializes end_ with ranges::end(parent.base_).
```

```
constexpr sentinel(sentinel<!Const> s)
requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
Effects: Initializes end_ with std::move(s.end_).
```

```
friend constexpr bool operator==(const iterator<Const>& x, const sentinel& y);
Effects: Equivalent to: return x.outer_ == y.end_;```  

§ 24.7.11 Split view

24.7.11.1 Overview

`split_view` takes a view and a delimiter, and splits the view into subranges on the delimiter. The delimiter can be a single element or a view of elements.

```
[Example:
  string str{"the quick brown fox"};
  split_view sentence(str, ' ');
  for (auto word : sentence) {
      for (char ch : word)
          cout << ch;
      cout << '*';
  }
  // The above prints: the*quick*brown*fox*
  — end example]
```

24.7.11.2 Class template `split_view`

```cpp
namespace std::ranges {
    template<auto> struct require-constant; // exposition only
    template<class R>
    concept tiny-range = // exposition only
        sized_range<R> &&
        requires { typename require-constant<remove_reference_t<R>::size>(); } &&
        (remove_reference_t<R>::size() <= 1);
```
```cpp
template<input_range V, forward_range Pattern>
requires view<V> && view<Pattern> &&
    indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
    (forward_range<V> || tiny_range<Pattern>)
class split_view : public view_interface<split_view<V, Pattern>> {
private:
    V base_ = V(); // exposition only
    Pattern pattern_ = Pattern(); // exposition only
    iterator_t<V> current_ = iterator_t<V>(); // exposition only, present only if !forward_range<V>
    // 24.7.11.3, class template split_view::outer_iterator
    template<bool> struct outer_iterator;
    // exposition only
    // 24.7.11.5, class template split_view::inner_iterator
    template<bool> struct inner_iterator;
    // exposition only
public:
    split_view() = default;
    constexpr split_view(V base, Pattern pattern);
    template<input_range R>
    requires constructible_from<V, views::all_t<R>> &&
        constructible_from<Pattern, single_view<range_value_t<R>>>
    constexpr split_view(R&& r, range_value_t<R> e);
    constexpr V base() const& requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }
    constexpr auto begin() {
        if constexpr (forward_range<V>)
            return outer_iterator<simple_view<V>>{*this, ranges::begin(base_)};
        else {
            current_ = ranges::begin(base_);
            return outer_iterator<false>{*this};
        }
    }
    constexpr auto begin() const requires forward_range<V> && forward_range<const V> {
        return outer_iterator<true>{*this, ranges::begin(base_)};
    }
    constexpr auto end() requires forward_range<V> && common_range<V> {
        return outer_iterator<simple_view<V>>{*this, ranges::end(base_)};
    }
    constexpr auto end() const {
        if constexpr (forward_range<V> && forward_range<const V> && common_range<const V>)
            return outer_iterator<true>{*this, ranges::end(base_)};
        else
            return default_sentinel;
    }
};

template<class R, class P>
split_view(R&&, P&&) -> split_view<views::all_t<R>, views::all_t<P>>;

template<input_range R>
split_view(R&&, range_value_t<R>)
    -> split_view<views::all_t<R>, single_view<range_value_t<R>>>;
}

constexpr split_view(V base, Pattern pattern);

Effects: Initializes base_ with std::move(base), and pattern_ with std::move(pattern).
```
constexpr split_view(R&& r, range_value_t<R> e);

Effects: Initializes base_ with views::all(std::forward<R>(r)), and pattern_ with single_view{ std::move(e)}.

24.7.11.3 Class template split_view::outer_iterator

namespace std::ranges {
    template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
        indirectly_comparable<iterator_t<V>, iterator_t<Pattern>>, ranges::equal_to &&
        (forward_range<V> || tiny_range<Pattern>)
    template<bool Const>
    struct split_view<V, Pattern>::outer_iterator {
        private:
            using Parent = // exposition only
                conditional_t<Const, const split_view, split_view>;
            using Base = // exposition only
                conditional_t<Const, const V, V>;
            Parent* parent_ = nullptr; // exposition only
            iterator_t<Base> current_ = // exposition only, present only if V models forward_range
                iterator_t<Base>();

        public:
            using iterator_concept = // exposition only
                conditional_t<forward_range<Base>, forward_iterator_tag, input_iterator_tag>;
            using iterator_category = input_iterator_tag;
            // 24.7.11.4, class split_view::outer_iterator::value_type
            struct value_type;
            using difference_type = range_difference_t<Base>;

            outer_iterator() = default;
            constexpr explicit outer_iterator(Parent& parent)
                requires (!forward_range<Base>);
            constexpr outer_iterator(Parent& parent, iterator_t<Base> current)
                requires forward_range<Base>;
            constexpr outer_iterator(outer_iterator<!Const> i)
                requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

            constexpr value_type operator*() const;
            constexpr outer_iterator& operator++();
            constexpr decltype(auto) operator++(int) { // exposition only
                if constexpr (forward_range<Base>) {
                    auto tmp = *this;
                    ++this;
                    return tmp;
                } else
                    +++this;
            }

            friend constexpr bool operator==(const outer_iterator& x, const outer_iterator& y)
                requires forward_range<Base>;

            friend constexpr bool operator==(const outer_iterator& x, default_sentinel_t);
        }
    }
}

§ 24.7.11.3

1 Many of the following specifications refer to the notional member current of outer_iterator. current is equivalent to current_ if V models forward_range, and parent_ -> current_ otherwise.

constexpr explicit outer_iterator(Parent& parent)
    requires (!forward_range<Base>);

Effects: Initializes parent_ with addressof(parent).
```cpp
constexpr outer_iterator(Parent& parent, iterator_t<Base> current)  
requires forward_range<Base>;

    Effects: Initializes parent_ with addressof(parent) and current_ with std::move(current).

constexpr outer_iterator(outer_iterator<Const> i)  
requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

    Effects: Initializes parent_ with i.parent_ and current_ with std::move(i.current_).

constexpr value_type operator*() const;

    Effects: Equivalent to: return value_type{*this};

constexpr outer_iterator& operator++();

    Effects: Equivalent to:
    const auto end = ranges::end(parent_->base_);  
    if (current == end) return *this;  
    const auto [pbegin, pend] = subrange{parent_->pattern_};  
    if (pbegin == pend) ++current;  
    else {
        do {
            auto [b, p] = ranges::mismatch(std::move(current), end, pbegin, pend);  
            current = std::move(b);  
            if (p == pend) {  
                break;  
                // The pattern matched; skip it
            }
        } while (++current != end);
    }
    return *this;

friend constexpr bool operator==(const outer_iterator& x, const outer_iterator& y)  
requires forward_range<Base>;

    Effects: Equivalent to: return x.current_ == y.current_;  

friend constexpr bool operator==(const outer_iterator& x, default_sentinel_t);

    Effects: Equivalent to: return x.current == ranges::end(x.parent_->base_);

§ 24.7.11.4 Class split_view::outer_iterator::value_type
```
constexpr inner-iterator<Const> begin() requires (!copyable<outer-iterator>);

   Effects: Equivalent to: return inner-iterator<Const>{std::move(i_)};

constexpr default_sentinel_t end() const;

   Effects: Equivalent to: return default_sentinel;

24.7.11.5 Class template split_view::inner-iterator

namespace std::ranges {
    template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
    indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
    (forward_range<V> || tiny-range<Pattern>)
    template<bool Const>
    struct split_view<V, Pattern>::inner-iterator {
        private:
            using Base = conditional_t<Const, const V, V>; // exposition only
            outer-iterator<Const> i_ = outer-iterator<Const>(); // exposition only
            bool incremented_ = false; // exposition only

        public:
            using iterator_concept = typename outer-iterator<Const>::iterator_concept;
            using iterator_category = see below;
            using value_type = range_value_t<Base>;
            using difference_type = range_difference_t<Base>;

            inner-iterator() = default;
            constexpr explicit inner-iterator(outer-iterator<Const> i);

            constexpr decltype(auto) operator*() const { return *i_.current; }

            constexpr inner-iterator& operator++();
            constexpr decltype(auto) operator++(int) {
                if constexpr (forward_range<V>) {
                    auto tmp = *this;
                    ++this;
                    return tmp;
                } else
                    ++this;
            }

            friend constexpr bool operator==(const inner-iterator& x, const inner-iterator& y)
            requires forward_range<Base>;

            friend constexpr bool operator==(const inner-iterator& x, default_sentinel_t);

            friend constexpr decltype(auto) iter_move(const inner-iterator& i)
            noexcept(noexcept(ranges::iter_move(i_.i_.current))) {
                return ranges::iter_move(i_.i_.current);
            }

            friend constexpr void iter_swap(const inner-iterator& x, const inner-iterator& y)
            noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current)))
            requires indirectly_swappable<iterator_t<Base>>;
        }
    }
}

1 The typedef-name iterator_category denotes:
(1.1) — forward_iterator_tag if iterator_traits<iterator_t<Base>>::iterator_category models derived_from<forward_iterator_tag>;
(1.2) — otherwise, iterator_traits<iterator_t<Base>>::iterator_category.

constexpr explicit inner-iterator(outer-iterator<Const> i);

   Effects: Initializes i_ with std::move(i).
constexpr inner_iterator& operator++();

Effects: Equivalent to:

incremented_ = true;
if constexpr (is_forward_range<Base>) {
    if constexpr (Pattern::size() == 0) {
        return *this;
    }
}  
++i_.current;
return *this;

friend constexpr bool operator==(const inner_iterator& x, const inner_iterator& y) requires forward_range<Base>;

Effects: Equivalent to: return x.i_.current == y.i_.current;

friend constexpr bool operator==(const inner_iterator& x, default_sentinel_t);

Effects: Equivalent to:

auto [pcur, pend] = subrange{x.i_.parent_->pattern_};
auto end = ranges::end(x.i_.parent_->base_);
if constexpr (is_tiny_range<Pattern>) {
    const auto & cur = x.i_.current;
    if (cur == end) return true;
    if (pcur == pend) return x.incremented_;
    return *cur == *pcur;
} else {
    auto cur = x.i_.current;
    if (cur == end) return true;
    if (pcur == pend) return x.incremented_;
    do {
        if (*cur != *pcur) return false;
        if (++pcur == pend) return true;
    } while (++cur != end);
    return false;
}

friend constexpr void iter_swap(const inner_iterator& x, const inner_iterator& y)
noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current))) requires indirectly_swappable<iterator_t<Base>>;

Effects: Equivalent to ranges::iter_swap(x.i_.current, y.i_.current).

24.7.12 Counted view [range.counted]

A counted view presents a view of the elements of the counted range (23.3.1) \(i + [0, n)\) for an iterator \(i\) and non-negative integer \(n\).

2 The name views::counted denotes a customization point object (16.4.2.2.6). Let \(E\) and \(F\) be expressions, let \(T\) be decay_t<decay_type(E)>, and let \(D\) be iter_difference_t<T>. If decay_type((F)) does not model convertible_to<D>, views::counted(E, F) is ill-formed. [Note: This case can result in substitution failure when views::counted(E, F) appears in the immediate context of a template instantiation. — end note] Otherwise, views::counted(E, F) is expression-equivalent to:

(2.1) If \(T\) models contiguous_iterator, then span(to_address(E), static_cast<D>(F)).

(2.2) Otherwise, if \(T\) models random_access_iterator, then subrange{E, E + static_cast<D>(F)}, except that \(E\) is evaluated only once.

(2.3) Otherwise, subrange{counted_iterator{E, F}, default_sentinel}.

24.7.13 Common view [range.common]

24.7.13.1 Overview [range.common.overview]

common_view takes a view which has different types for its iterator and sentinel and turns it into a view of the same elements with an iterator and sentinel of the same type.
Note: `common_view` is useful for calling legacy algorithms that expect a range's iterator and sentinel types to be the same. — end note

The name `views::common` denotes a range adaptor object (24.7.1). Given a subexpression `E`, the expression `views::common(E)` is expression-equivalent to:

1. `views::all(E)`, if `decltype((E))` models `common_range` and `views::all(E)` is a well-formed expression.
2. Otherwise, `common_view(E)`.

Example:

```cpp
// Legacy algorithm:
template<class ForwardIterator>
size_t count(ForwardIterator first, ForwardIterator last);

template<forward_range R>
void my_algo(R&& r) {
    auto&& common = common_view{r};
    auto cnt = count(common.begin(), common.end());
    // ...
}
```

— end example

24.7.13.2 Class template `common_view`

```cpp
namespace std::ranges {
    namespace detail {
        template<view V>
        requires (!common_range<V> && copyable<iterator_t<V>>)  // exposition only
        class common_view : public view_interface<common_view<V>> {
            private:
                V base_ = V();

            public:
                common_view() = default;
                constexpr explicit common_view(V r);
            
                template<viewable_range R>
                requires (!common_range<R> && constructible_from<V, views::all_t<R>>)
                constexpr explicit common_view(R&& r);

                constexpr V base() const requires copy_constructible<V> { return base_; }
                constexpr V base() && { return std::move(base_); }

                constexpr auto begin() {
                    if constexpr (random_access_range<V> && sized_range<V>)
                        return ranges::begin(base_);
                    else
                        return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::begin(base_));
                }

                constexpr auto begin() const requires range<const V> {
                    if constexpr (random_access_range<const V> && sized_range<const V>)
                        return ranges::begin(base_);
                    else
                        return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::begin(base_));
                }

                constexpr auto end() {
                    if constexpr (random_access_range<V> && sized_range<V>)
                        return ranges::begin(base_) + ranges::size(base_);
                    else
                        return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::end(base_));
                }
            }
        }
    }
    
    template<view V>
    requires (!common_range<V> && copyable<iterator_t<V>>)  // exposition only
    class common_view : public view_interface<common_view<V>> {
        private:
            V base_ = V();

        public:
            common_view() = default;
            constexpr explicit common_view(V r);
        
            template<viewable_range R>
            requires (!common_range<R> && constructible_from<V, views::all_t<R>>)
            constexpr explicit common_view(R&& r);

            constexpr V base() const requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr auto begin() {
                if constexpr (random_access_range<V> && sized_range<V>)
                    return ranges::begin(base_);
                else
                    return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::begin(base_));
            }

            constexpr auto begin() const requires range<const V> {
                if constexpr (random_access_range<const V> && sized_range<const V>)
                    return ranges::begin(base_);
                else
                    return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::begin(base_));
            }

            constexpr auto end() {
                if constexpr (random_access_range<V> && sized_range<V>)
                    return ranges::begin(base_) + ranges::size(base_);
                else
                    return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::end(base_));
            }
        }
    }
}
```

§ 24.7.13.2
constexpr auto end() const requires range<const V> {
    if constexpr (random_access_range<const V> && sized_range<const V>)
        return ranges::begin(base_) + ranges::size(base_);
    else
        return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::end(base_));
}

constexpr auto size() requires sized_range<V> {
    return ranges::size(base_);
}
constexpr auto size() const requires sized_range<const V> {
    return ranges::size(base_);
};

template<class R>
common_view(R&&) -> common_view<views::all_t<R>>;

constexpr explicit common_view(V base);
Effects: Initializes base_ with std::move(base).

template<viewable_range R>
requires (!common_range<R> && constructible_from<V, views::all_t<R>>)
constexpr explicit common_view(R&& r);
Effects: Initializes base_ with views::all(std::forward<R>(r)).

§ 24.7.14 Reverse view

24.7.14.1 Overview

reverse_view takes a bidirectional view and produces another view that iterates the same elements in reverse order.

1. The name views::reverse denotes a range adaptor object (24.7.1). Given a subexpression E, the expression views::reverse(E) is expression-equivalent to:

   (2.1) — If the type of E is a (possibly cv-qualified) specialization of reverse_view, equivalent to E.base().

   (2.2) — Otherwise, if the type of E is cv-qualified
            subrange<reverse_iterator<I>, reverse_iterator<I>, K>
            for some iterator type I and value K of type subrange_kind,
              — if K is subrange_kind::sized, equivalent to:
              subrange<I, I, K>(E.end().base(), E.begin().base(), E.size())
              — otherwise, equivalent to:
              subrange<I, I, K>(E.end().base(), E.begin().base())

   However, in either case E is evaluated only once.

   (2.3) — Otherwise, equivalent to reverse_view{E}.

   [Example:
     vector<int> is {0,1,2,3,4};
     reverse_view rv (is);
     for (int i : rv)
         cout << i << ' '; // prints: 4 3 2 1 0
   — end example]

24.7.14.2 Class template reverse_view

namespace std::ranges {
    template<typename V>
    requires bidirectional_range<typename V>
    class reverse_view : public view_interface<reverse_view<typename V>> {
        private:
V base_ = V(); // exposition only
public:
  reverse_view() = default;

constexpr explicit reverse_view(V r);

constexpr V base() const& requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }

constexpr reverse_iterator<iterator_t<V>> begin();
constexpr auto begin() requires common_range<V>;
constexpr reverse_iterator<iterator_t<V>> end();
constexpr auto end() const requires common_range<const V>;

constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
constexpr auto size() const requires sized_range<const V> { return ranges::size(base_); }

};

template<class R>
reverse_view(R&&) -> reverse_view<views::all_t<R>>;

constexpr explicit reverse_view(V base);

Effects: Initializes base_ with std::move(base).

constexpr reverse_iterator<iterator_t<V>> begin();

Returns:
make_reverse_iterator(ranges::next(ranges::begin(base_), ranges::end(base_)))

Remarks: In order to provide the amortized constant time complexity required by the range concept, this
function caches the result within the reverse_view for use on subsequent calls.

constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;
constexpr auto begin() const requires common_range<const V>;

Effects: Equivalent to: return make_reverse_iterator(ranges::end(base_));

constexpr reverse_iterator<iterator_t<V>> end();
constexpr auto end() const requires common_range<const V>;

Effects: Equivalent to: return make_reverse_iterator(ranges::begin(base_));

24.7.15 Elements view

24.7.15.1 Overview

elements_view takes a view of tuple-like values and a size_t, and produces a view with a value-type of the N\textsuperscript{th}
element of the adapted view’s value-type.

The name views::elements<N> denotes a range adaptor object (24.7.1). Given a subexpression E and constant expression N, the expression views::elements<N>(E) is expression-equivalent to elements_view<views::all_t<decltype((E))>, N>{E}.

Example:
auto historical_figures = map{
  {"Lovelace"sv, 1815},
  {"Turing"sv, 1912},
  {"Babbage"sv, 1791},
  {"Hamilton"sv, 1936}
};
auto names = historical_figures | views::elements<0>;
for (auto&& name : names) {
    cout << name << ' ';  // prints Babbage Hamilton Lovelace Turing
}

auto birth_years = historical_figures | views::elements<1>;
for (auto&& born : birth_years) {
    cout << born << ' ';  // prints 1791 1936 1815 1912
}

— end example]

3 keys_view is an alias for elements_view<views::all_t<R>, 0>, and is useful for extracting keys from associative containers.

[Example:
    auto names = keys_view{historical_figures};
    for (auto&& name : names) {
        cout << name << ' ';  // prints Babbage Hamilton Lovelace Turing
    }
    — end example

4 values_view is an alias for elements_view<views::all_t<R>, 1>, and is useful for extracting values from associative containers.

[Example:
    auto is_even = [](const auto x) { return x % 2 == 0; };
    cout << ranges::count_if(values_view{historical_figures}, is_even);  // prints 2
    — end example

24.7.15.2  Class template elements_view

namespace std::ranges {

    template<class T, size_t N>
    concept has-tuple-element =
    // exposition only
    requires(T t) {
        typename tuple_size<T>::type;
        requires N < tuple_size_v<T>;
        typename tuple_element_t<N, T>;
        { get<N>(t) } -> convertible_to<const tuple_element_t<N, T>&>;
    };

    template<input_range V, size_t N>
    requires view<V> &&
    has-tuple-element<range_value_t<V>, N> &&
    has-tuple-element<remove_reference_t<range_reference_t<V>>, N>
    class elements_view : public view_interface<elements_view<V, N>> {
        public:
            elements_view() = default;
            constexpr explicit elements_view(V base) {
                std::ranges::begin(base_);
            }
            constexpr V base() const requires copy_constructible<V> {
                return base_; }
            constexpr V base() && {
                return std::move(base_); }

            constexpr auto begin() requires (!simple_view<V>)
            { return iterator<false>(ranges::begin(base_)); };

            constexpr auto begin() const requires simple_view<V>

25 Algoritms library

25.1 General

This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 22) and other sequences.

The following subclauses describe components for non-modifying sequence operations, mutating sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 91.

Table 91: Algorithms library summary

25.2 Algorithms requirements

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

The entities defined in the std::ranges namespace in this Clause are not found by argument-dependent name lookup (6.5.2). When found by unqualified (6.5.1) name lookup for the postfix-expression in a function call (7.6.1.2), they inhibit argument-dependent name lookup.

[Example]

```cpp
void foo() {
    using namespace std::ranges;
    std::vector<int> vec{1, 2, 3};
    find(begin(vec), end(vec), 2); // #1
}
```

The function call expression at #1 invokes std::ranges::find, not std::find, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::find is more specialized (13.7.6.2) than std::ranges::find since the former requires its first two parameters to have the same type. ~ end example]

For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

Throughout this Clause, where the template parameters are not constrained, the names of template parameters are used to express type requirements.

- If an algorithm’s template parameter is named InputIterator, InputIterator1, or InputIterator2, the template argument shall meet the Cpp17InputIterator requirements (23.3.5.2).
- If an algorithm’s template parameter is named OutputIterator, OutputIterator1, or OutputIterator2, the template argument shall meet the Cpp17OutputIterator requirements (23.3.5.3).
- If an algorithm’s template parameter is named ForwardIterator, ForwardIterator1, or ForwardIterator2, the template argument shall meet the Cpp17ForwardIterator requirements (23.3.5.4).
If an algorithm’s template parameter is named `NoThrowForwardIterator`, the template argument shall meet the `Cpp17ForwardIterator` requirements (23.3.5.4), and is required to have the property that no exceptions are thrown from increment, assignment, or comparison of, or indirection through, valid iterators.

If an algorithm’s template parameter is named `BidirectionalIterator`, `BidirectionalIterator1`, or `BidirectionalIterator2`, the template argument shall meet the `Cpp17BidirectionalIterator` requirements (23.3.5.5).

If an algorithm’s template parameter is named `RandomAccessIterator`, `RandomAccessIterator1`, or `RandomAccessIterator2`, the template argument shall meet the `Cpp17RandomAccessIterator` requirements (23.3.5.6).

If an algorithm’s `Effects` element specifies that a value pointed to by any iterator passed as an argument is modified, then that algorithm has an additional type requirement: The type of that argument shall meet the requirements of a mutable iterator (23.3). [Note: This requirement does not affect arguments that are named `OutputIterator`, `OutputIterator1`, or `OutputIterator2`, because output iterators must always be mutable, nor does it affect arguments that are constrained, for which mutability requirements are expressed explicitly. —end note]

Both in-place and copying versions are provided for certain algorithms. When such a version is provided for algorithm it is called `algorithm_copy`. Algorithms that take predicates end with the suffix `_copy`.

When not otherwise constrained, the `Predicate` parameter is used whenever an algorithm expects a function object (20.14) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as `true`. In other words, if an algorithm takes `Predicate pred` as its argument and `first` as its iterator argument with value type `T`, it should work correctly in the construct `pred(*first)` contextually converted to `bool` (7.3). The function object `pred` shall not apply any non-constant function through the dereferenced iterator. Given a glvalue `u` of type (possibly `const`) `T` that designates the same object as `*first`, `pred(u)` shall be a valid expression that is equal to `pred(*first)`.

When not otherwise constrained, the `BinaryPredicate` parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type `T` when `T` is part of the signature returns a value testable as `true`. In other words, if an algorithm takes `BinaryPredicate binary_pred` as its argument and `first1` and `first2` as its iterator arguments with respective value types `T1` and `T2`, it should work correctly in the construct `binary_pred(*first1, *first2)` contextually converted to `bool` (7.3). Unless otherwise specified, `BinaryPredicate` always takes the first iterator’s `value_type` as its first argument, that is, in those cases when `T` value is part of the signature, it should work correctly in the construct `binary_pred(*first1, value)` contextually converted to `bool` (7.3). `Binary_pred` shall not apply any non-constant function through the dereferenced iterators. Given a glvalue `u` of type (possibly `const`) `T1` that designates the same object as `*first1`, and a glvalue `v` of type (possibly `const`) `T2` that designates the same object as `*first2`, `binary_pred(u, *first2)`, `binary_pred(*first1, v)`, and `binary_pred(u, v)` shall each be a valid expression that is equal to `binary_pred(*first1, *first2)`, and `binary_pred(u, value)` shall be a valid expression that is equal to `binary_pred(*first1, value)`.

The parameters `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, and `BinaryOperation2` are used whenever an algorithm expects a function object (20.14).

[Note: Unless otherwise specified, algorithms that take function objects as arguments are permitted to copy those function objects freely. Programmers for whom object identity is important should consider using a wrapper class that points to a noncopied implementation object such as `reference_wrapper<T>` (20.14.5), or some equivalent solution. —end note]

When the description of an algorithm gives an expression such as `*first == value` for a condition, the expression shall evaluate to either `true` or `false` in boolean contexts.

In the description of the algorithms, operator `+` is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of `a + n` are the same as those of

```cpp
auto tmp = a;
for (; n < 0; ++n) --tmp;
for (; n > 0; --n) ++tmp;
return tmp;
```

---

230) The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, `sort_copy` is not included because the cost of sorting is much more significant, and users might as well do `copy` followed by `sort`. 

§ 25.2
Similarly, operator \(-\) is used for some combinations of iterators and sentinel types for which it does not have to be defined. If \([a, b)\) denotes a range, the semantics of \(b - a\) in these cases are the same as those of

\[
\text{iter\_difference}_{T}\langle\text{decltype}\langle a\rangle\rangle \ n = 0;
\text{for} \ (\text{auto} \ \text{tmp} = a; \ \text{tmp} \ != b; \ ++\text{tmp}) \ ++\text{n};
\text{return} \ \text{n};
\]

and if \([b, a)\) denotes a range, the same as those of

\[
\text{iter\_difference}_{T}\langle\text{decltype}\langle b\rangle\rangle \ n = 0;
\text{for} \ (\text{auto} \ \text{tmp} = b; \ \text{tmp} \ != a; \ ++\text{tmp}) \ --\text{n};
\text{return} \ \text{n};
\]

In the description of algorithm return values, a sentinel value \(s\) denoting the end of a range \([i, s)\) is sometimes returned where an iterator is expected. In these cases, the semantics are as if the sentinel is converted into an iterator using \(\text{ranges::next}\langle i, s\rangle\).

Overloads of algorithms that take \texttt{range} arguments (24.4.2) behave as if they are implemented by calling \texttt{ranges::begin} and \texttt{ranges::end} on the range(s) and dispatching to the overload in namespace \texttt{ranges} that takes separate iterator and sentinel arguments.

The number and order of deducible template parameters for algorithm declarations are unspecified, except where explicitly stated otherwise. \[\text{Note: Consequently, the algorithms may not be called with explicitly-specified template argument lists. — end note}\]

### 25.3 Parallel algorithms

#### 25.3.1 Preamble

A parallel algorithm is a function template listed in this document with a template parameter named \texttt{ExecutionPolicy}.

Parallel algorithms access objects indirectly accessible via their arguments by invoking the following functions:

- All operations of the categories of the iterators that the algorithm is instantiated with.
- Operations on those sequence elements that are required by its specification.
- User-provided function objects to be applied during the execution of the algorithm, if required by the specification.
- Operations on those function objects required by the specification. \[\text{Note: See 25.2. — end note}\]

These functions are herein called element access functions. \[\text{Example: The sort function may invoke the following element access functions:}\]

- Operations of the random-access iterator of the actual template argument (as per 23.3.5.6), as implied by the name of the template parameter \texttt{RandomAccessIterator}.
- The \texttt{swap} function on the elements of the sequence (as per the preconditions specified in 25.8.1.1).
- The user-provided \texttt{Compare} function object.

A standard library function is vectorization-unsafe if it is specified to synchronize with another function invocation, or another function invocation is specified to synchronize with it, and if it is not a memory allocation or deallocation function. \[\text{Note: Implementations must ensure that internal synchronization inside standard library functions does not prevent forward progress when those functions are executed by threads of execution with weakly parallel forward progress guarantees. — end note}\]

\[\text{Example:}\]

```cpp
int x = 0;
std::mutex m;
void f() {
    int a[] = {1,2};
    std::for_each(std::execution::par_unseq, std::begin(a), std::end(a), [&](int) {
        std::lock_guard<mutex> guard(m); // incorrect: lock_guard constructor calls m.lock()
        ++x;
    });
}
```
The above program may result in two consecutive calls to std::jthread() on the same thread of execution (which may deadlock), because the applications of the function object are not guaranteed to run on different threads of execution. — end example

25.3.2 Requirements on user-provided function objects

Unless otherwise specified, function objects passed into parallel algorithms as objects of type Predicate, Compare, UnaryOperation, BinaryOperation, BinaryOperation1, BinaryOperation2, and the operators used by the analogous overloads to these parallel algorithms that could be formed by the invocation with the specified default predicate or operation (where applicable) shall not directly or indirectly modify objects via their arguments, nor shall they rely on the identity of the provided objects.

25.3.3 Effect of execution policies on algorithm execution

Parallel algorithms have template parameters named ExecutionPolicy (20.18) which describe the manner in which the execution of these algorithms may be parallelized and the manner in which they apply the element access functions.

If an object is modified by an element access function, the algorithm will perform no other unsynchronized accesses to that object. The modifying element access functions are those which are specified as modifying the object. [Note: For example, swap, ++, --, @=, and assignments modify the object. For the assignment and @= operators, only the left argument is modified. — end note]

Unless otherwise stated, implementations may make arbitrary copies of elements (with type T) from sequences where is_trivially_copy_constructible_v<T> and is_trivially_destructible_v<T> are true. [Note: This implies that user-supplied function objects should not rely on object identity of arguments for such input sequences. Users for whom the object identity of the arguments to these function objects is important should consider using a wrapping iterator that returns a non-copied implementation object such as reference_wrapper<T> (20.14.5) or some equivalent solution. — end note]

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type execution::sequenced_policy all occur in the calling thread of execution. [Note: The invocations are not interleaved; see 6.9.1. — end note]

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type execution::unsequenced_policy are permitted to execute in an unordered fashion in the calling thread of execution, unsequenced with respect to one another in the calling thread of execution. [Note: This means that multiple function object invocations may be interleaved on a single thread of execution, which overrides the usual guarantee from 6.9.1 that function executions do not overlap with one another. — end note] The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from a execution::unsequenced_policy algorithm. [Note: Because execution::unsequenced_policy allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. — end note]

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type execution::parallel_policy are permitted to execute either in the invoking thread of execution or in a thread of execution implicitly created by the library to support parallel algorithm execution. If the threads of execution created by thread (32.4.2) or jthread (32.4.3) provide concurrent forward progress guarantees (6.9.2.2), then a thread of execution implicitly created by the library will provide parallel forward progress guarantees; otherwise, the provided forward progress guarantee is implementation-defined. Any such invocations executing in the same thread of execution are indeterminately sequenced with respect to each other. [Note: It is the caller’s responsibility to ensure that the invocation does not introduce data races or deadlocks. — end note] [Example:

```c++
int a[] = {0,1};
std::vector<int> v;
std::for_each(std::execution::par, std::begin(a), std::end(a), [&] (int i) {
  v.push_back(i*2+1);
  // incorrect: data race
});
```

The program above has a data race because of the unsynchronized access to the container v. — end example]

[Example:

```c++
std::atomic<int> x{0};
int a[] = {1,2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&] (int) {
  x.fetch_add(1, std::memory_order::relaxed);
});
```]
// spin wait for another iteration to change the value of x 
while (x.load(std::memory_order::relaxed) == 1) { } // incorrect: assumes execution order

The above example depends on the order of execution of the iterations, and will not terminate if both iterations are executed sequentially on the same thread of execution. — end example] [Example:

```cpp
text int x = 0;
std::mutex m;
int a[2] = {1, 2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    std::lock_guard<mutex> guard(m);
    ++x;
});
```

The above example synchronizes access to object x ensuring that it is incremented correctly. — end example]

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::parallel_unsequenced_policy` are permitted to execute in an unordered fashion in unspecified threads of execution, and unsequenced with respect to one another within each thread of execution. These threads of execution are either the invoking thread of execution or threads of execution implicitly created by the library; the latter will provide weakly parallel forward progress guarantees. [Note: This means that multiple function object invocations may be interleaved on a single thread of execution, which overrides the usual guarantee from §6.9.1 that function executions do not overlap with one another. — end note] The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from an execution::parallel_unsequenced_policy algorithm. [Note: Because execution::parallel_unsequenced_policy allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. — end note]

[Note: The semantics of invocation with execution::unsequenced_policy, execution::parallel_policy, or execution::parallel_unsequenced_policy allow the implementation to fall back to sequential execution if the system cannot parallelize an algorithm invocation, e.g., due to lack of resources. — end note]

If an invocation of a parallel algorithm uses threads of execution implicitly created by the library, then the invoking thread of execution will either

- temporarily block with forward progress guarantee delegation (§6.9.2.2) on the completion of these library-managed threads of execution, or
- eventually execute an element access function;

the thread of execution will continue to do so until the algorithm is finished. [Note: In blocking with forward progress guarantee delegation in this context, a thread of execution created by the library is considered to have finished execution as soon as it has finished the execution of the particular element access function that the invoking thread of execution logically depends on. — end note]

The semantics of parallel algorithms invoked with an execution policy object of implementation-defined type are implementation-defined.

### § 25.3.4 Parallel algorithm exceptions

[algorithms.parallel.exceptions]

1. During the execution of a parallel algorithm, if temporary memory resources are required for parallelization and none are available, the algorithm throws a `bad_alloc` exception.
2. During the execution of a parallel algorithm, if the invocation of an element access function exits via an uncaught exception, the behavior is determined by the `ExecutionPolicy`.

### § 25.3.5 ExecutionPolicy algorithm overloads

[algorithms.parallel.overloads]

1. Parallel algorithms are algorithm overloads. Each parallel algorithm overload has an additional template type parameter named `ExecutionPolicy`, which is the first template parameter. Additionally, each parallel algorithm overload has an additional function parameter of type `ExecutionPolicy&&`, which is the first function parameter. [Note: Not all algorithms have parallel algorithm overloads. — end note]
2. Unless otherwise specified, the semantics of `ExecutionPolicy` algorithm overloads are identical to their overloads without.
3. Unless otherwise specified, the complexity requirements of `ExecutionPolicy` algorithm overloads are relaxed from the complexity requirements of the overloads without as follows: when the guarantee says “at most expr” or “exactly
expr" and does not specify the number of assignments or swaps, and expr is not already expressed with $O()$ notation, the complexity of the algorithm shall be $O(expr)$.

4 Parallel algorithms shall not participate in overload resolution unless is_execution_policy_v<remove_cvref_t<ExecutionPolicy>> is true.

25.4 Header <algorithm> synopsis

```cpp
#include <initializer_list>

namespace std {

namespace ranges {

    // 25.5, algorithm result types

    constexpr operator in_found_result<I2>() && {
        return {std::move(in), found};
    }
};

25.6 Non-modifying sequence operations [alg.nonmodifying]

25.6.1 All of [alg.all.of]

template<class InputIterator, class Predicate>
constexpr bool all_of(InputIterator first, InputIterator last, Predicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool all_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::all_of(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::all_of(R&& r, Pred pred, Proj proj = {});

Let $E$ be:

1. $\text{pred}(*i)$ for the overloads in namespace std;
2. $\text{invoke}(<\text{pred}, \text{invoke}(<\text{proj}, *i)>)$ for the overloads in namespace ranges.

Returns: false if $E$ is false for some iterator $i$ in the range $[\text{first}, \text{last})$, and true otherwise.

Complexity: At most last - first applications of the predicate and any projection.

### 25.6.2 Any of

```cpp
template<class InputIterator, class Predicate>
constexpr bool any_of(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool any_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::any_of(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::any_of(R&& r, Pred pred, Proj proj = {});
```

Let $E$ be:

1. $\text{pred}(*i)$ for the overloads in namespace std;
2. $\text{invoke}(<\text{pred}, \text{invoke}(<\text{proj}, *i)>)$ for the overloads in namespace ranges.

Returns: true if $E$ is true for some iterator $i$ in the range $[\text{first}, \text{last})$, and false otherwise.

Complexity: At most last - first applications of the predicate and any projection.

### 25.6.3 None of

```cpp
template<class InputIterator, class Predicate>
constexpr bool none_of(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool none_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::none_of(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::none_of(R&& r, Pred pred, Proj proj = {});
```

Let $E$ be:

1. $\text{pred}(*i)$ for the overloads in namespace std;
2. $\text{invoke}(<\text{pred}, \text{invoke}(<\text{proj}, *i)>)$ for the overloads in namespace ranges.

Returns: false if $E$ is true for some iterator $i$ in the range $[\text{first}, \text{last})$, and true otherwise.

Complexity: At most last - first applications of the predicate and any projection.
25.6.4 For each

```cpp
template<class InputIterator, class Function>
constexpr Function for_each(InputIterator first, InputIterator last, Function f);
```

1. **Preconditions:** Function meets the `Cpp17MoveConstructible` requirements (Table 28). [Note: Function need not meet the requirements of `Cpp17CopyConstructible` (Table 29). — end note]
2. **Effects:** Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{last})\), starting from \( \text{first} \) and proceeding to \( \text{last} - 1 \). [Note: If the type of \( \text{first} \) meets the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator. — end note]
3. **Returns:** \( f \).
4. **Complexity:** Applies \( f \) exactly \( \text{last} - \text{first} \) times.
5. **Remarks:** If \( f \) returns a result, the result is ignored.

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Function>
void for_each(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Function f);
```

6. **Preconditions:** Function meets the `Cpp17CopyConstructible` requirements.
7. **Effects:** Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{last})\). [Note: If the type of \( \text{first} \) meets the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator. — end note]
8. **Complexity:** Applies \( f \) exactly \( \text{last} - \text{first} \) times.
9. **Remarks:** If \( f \) returns a result, the result is ignored. Implementations do not have the freedom granted under 25.3.3 to make arbitrary copies of elements from the input sequence. [Note: Does not return a copy of its `Function` parameter, since parallelization may not permit efficient state accumulation. — end note]

```cpp
template<input_iterator I, sentinel_for<I> S, class Proj = identity, indirectly_unary_invocable<projected<I, Proj>> Fun>
constexpr ranges::for_each_result<I, Fun> ranges::for_each(I first, S last, Fun f, Proj proj = {});
```

10. **Effects:** Calls \( \text{invoke}(f, \text{invoke}(\text{proj}, *i)) \) for every iterator \( i \) in the range \([\text{first}, \text{last})\), starting from \( \text{first} \) and proceeding to \( \text{last} - 1 \). [Note: If the result of \( \text{invoke}(\text{proj}, *i) \) is a mutable reference, \( f \) may apply non-constant functions. — end note]
11. **Returns:** \( \text{last}, \text{std::move}(f) \).
12. **Complexity:** Applies \( f \) and \( \text{proj} \) exactly \( \text{last} - \text{first} \) times.
13. **Remarks:** If \( f \) returns a result, the result is ignored. [Note: The overloads in namespace `ranges` require `Fun` to model `copy_constructible`. — end note]

```cpp
template<class InputIterator, class Size, class Function>
constexpr InputIterator for_each_n(InputIterator first, Size n, Function f);
```

14. **Mandates:** The type `Size` is convertible to an integral type (7.3.8, 11.4.7).
15. **Preconditions:** \( n >= 0 \) is true. Function meets the `Cpp17MoveConstructible` requirements. [Note: Function need not meet the requirements of `Cpp17CopyConstructible`. — end note]
16. **Effects:** Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first} + n)\) in order. [Note: If the type of \( \text{first} \) meets the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator. — end note]
17. **Returns:** \( \text{first} + n \).
18. **Remarks:** If \( f \) returns a result, the result is ignored.
template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
ForwardIterator for_each_n(ExecutionPolicy&& exec, ForwardIterator first, Size n,
    Function f);

Mandates: The type Size is convertible to an integral type (7.3.8, 11.4.7).
Preconditions: n >= 0 is true. Function meets the Cpp17CopyConstructible requirements.
Effects: Applies f to the result of dereferencing every iterator in the range [first, first + n]. [Note: If
the type of first meets the requirements of a mutable iterator, f may apply non-constant functions through
the dereferenced iterator. — end note]
Returns: first + n.
Remarks: If f returns a result, the result is ignored. Implementations do not have the freedom granted under
25.3.3 to make arbitrary copies of elements from the input sequence.

template<input_iterator I, class Proj = identity,
    indirectly_unary_invocable<projected<I,Proj>> Fun>
constexpr ranges::for_each_n_result<I, Fun>
    ranges::for_each_n(I first, iter_difference_t<I> n, Fun f, Proj proj = {});

Preconditions: n >= 0 is true.
Effects: Calls invoke(f, invoke(proj, *i)) for every iterator i in the range [first, first + n) in
order. [Note: If the result of invoke(proj, *i) is a mutable reference, f may apply non-constant functions.
— end note]
Returns: {first + n, std::move(f)}.
Remarks: If f returns a result, the result is ignored.
[Note: The overload in namespace ranges requires Fun to model copy_constructible. — end note]

25.6.5  Find

template<class InputIterator, class T>            
    constexpr InputIterator find(InputIterator first, InputIterator last,
        const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>  
    ForwardIterator find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
        const T& value);

template<class InputIterator, class Predicate>  
    constexpr InputIterator find_if(InputIterator first, InputIterator last,
        Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>  
    ForwardIterator find_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
        Predicate pred);

template<class InputIterator, class Predicate>  
    constexpr InputIterator find_if_not(InputIterator first, InputIterator last,
        Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>  
    ForwardIterator find_if_not(ExecutionPolicy&& exec,
        ForwardIterator first, ForwardIterator last,
        Predicate pred);

template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity>  
    requires indirect_binary_predicate ranges::equal_to, projected<I, Proj>, const T*>  
    constexpr I ranges::find(I first, S last, const T& value, Proj proj = {});

template<input_range R, class T, class Proj = identity>  
    requires indirect_binary_predicate ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>  
    constexpr borrowed_iterator_t<R>  
    ranges::find(R&& r, const T& value, Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_unary_predicate projected<I, Proj>> Pred>  
    constexpr I ranges::find_if(I first, S last, Pred pred, Proj proj = {});
template<input_range R, class Proj = identity,
  indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr borrowed_iterator_t<R>
ranges::find_if(R&& r, Pred pred, Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
  indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr I ranges::find_if_not(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity,
  indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr borrowed_iterator_t<R>
ranges::find_if_not(R&& r, Pred pred, Proj proj = {});

Let $E$ be:

1. $i == \text{value}$ for find;
2. $\text{pred}(i) \neq \text{false}$ for find_if;
3. $\text{pred}(i) == \text{false}$ for find_if_not;
4. $\text{bool} (\text{invoke} (\text{proj}, *i) == \text{value})$ for ranges::find;
5. $\text{bool} (\text{invoke} (\text{pred}, \text{invoke} (\text{proj}, *i)))$ for ranges::find_if;
6. $\text{bool} (\text{!invoke} (\text{pred}, \text{invoke} (\text{proj}, *i)))$ for ranges::find_if_not.

Returns: The first iterator $i$ in the range $[\text{first}, \text{last})$ for which $E$ is true. Returns last if no such iterator is found.

Complexity: At most last - first applications of the corresponding predicate and any projection.

### 25.6.6 Find end

#### 25.6.6.1 Find end

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1
find_end(ForwardIterator1 first1, ForwardIterator1 last1,
         ForwardIterator2 first2, ForwardIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
find_end(ExecutionPolicy&& exec,
         ForwardIterator1 first1, ForwardIterator1 last1,
         ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
constexpr ForwardIterator1
find_end(ForwardIterator1 first1, ForwardIterator1 last1,
         ForwardIterator2 first2, ForwardIterator2 last2,
         BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
ForwardIterator1
find_end(ExecutionPolicy&& exec,
         ForwardIterator1 first1, ForwardIterator1 last1,
         ForwardIterator2 first2, ForwardIterator2 last2,
         BinaryPredicate pred);

template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr subrange<I1>
ranges::find_end(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
                 Proj1 proj1 = {}, Proj2 proj2 = {});

template<forward_range R1, forward_range R2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_subrange_t<R1>
ranges::find_end(R1&& r1, R2&& r2, Pred pred = {});
```
Proj1 proj1 = {}; Proj2 proj2 = {};

Let:
(1.1) pred be `equal_to()` for the overloads with no parameter pred;
(1.2) E be:
(1.2.1) pred(*(i + n), *(first2 + n)) for the overloads in namespace std;
(1.2.2) invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n))) for the overloads in namespace ranges;
(1.3) i be last1 if \([first2, last2)\) is empty, or if \((last2 - first2) > (last1 - first1)\) is true, or if there is no iterator in the range \([first1, last1 - (last2 - first2))\) such that for every non-negative integer \(n < (last2 - first2)\), \(E\) is true. Otherwise \(i\) is the last such iterator in \([first1, last1 - (last2 - first2))\).

Returns:
(2.1) \(i\) for the overloads in namespace std.
(2.2) \(\{i, i + (i == last1 ? 0 : last2 - first2)\}\) for the overloads in namespace ranges.

Complexity: At most \((last2 - first2) * (last1 - first1 - (last2 - first2) + 1)\) applications of the corresponding predicate and any projections.

25.6.7 Find /f_irst [alg/first_of]

template<class InputIterator, class ForwardIterator>
constexpr InputIterator
find_first_of(InputIterator first1, InputIterator last1, ForwardIterator first2, ForwardIterator last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
find_first_of(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator, class ForwardIterator, class BinaryPredicate>
constexpr InputIterator
find_first_of(InputIterator first1, InputIterator last1, ForwardIterator first2, ForwardIterator last2, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
ForwardIterator1
find_first_of(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2, BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr I1
ranges::find_first_of(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, forward_range R2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_iterator_t<R1>
ranges::find_first_of(R1&& r1, R2&& r2,
Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

Let \(E\) be:
(1.1) \(*i == *j\) for the overloads with no parameter pred;
— pred(*i, *j) != false for the overloads with a parameter pred and no parameter proj1;
— bool(invoke(pred, invoke(proj1, *i), invoke(proj2, *j))) for the overloads with parameters pred and proj1.

Effects: Finds an element that matches one of a set of values.

Returns: The first iterator i in the range [first1, last1) such that for some iterator j in the range [first2, last2) E holds. Returns last1 if [first2, last2) is empty or if no such iterator is found.

Complexity: At most (last1-first1) * (last2-first2) applications of the corresponding predicate and any projections.

25.6.8 Adjacent find

template<class ForwardIterator>
constexpr ForwardIterator
adjacent_find(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
adjacent_find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator
adjacent_find(ForwardIterator first, ForwardIterator last, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator
adjacent_find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, BinaryPredicate pred);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity, indirect_binary_predicate<projected<I, Proj>, projected<I, Proj>> Pred = ranges::equal_to>
constexpr I ranges::adjacent_find(I first, S last, Pred pred = {}, Proj proj = {});
template<forward_range R, class Proj = identity, indirect_binary_predicate<projected<iterator_t<R>, Proj>, projected<iterator_t<R>, Proj>> Pred = ranges::equal_to>
constexpr borrowed_iterator_t<R> ranges::adjacent_find(R&& r, Pred pred = {}, Proj proj = {});

Let E be:

— *i == *(i + 1) for the overloads with no parameter pred;
— pred(*i, *(i + 1)) != false for the overloads with a parameter pred and no parameter proj;
— bool(invoke(pred, invoke(proj, *i), invoke(proj, *(i + 1)))) for the overloads with both parameters pred and proj.

Returns: The first iterator i such that both i and i + 1 are in the range [first, last) for which E holds. Returns last if no such iterator is found.

Complexity: For the overloads with no ExecutionPolicy, exactly

\[ \min((i - first) + 1, (last - first) - 1) \]

applications of the corresponding predicate, where i is adjacent_find’s return value. For the overloads with an ExecutionPolicy, O(last - first) applications of the corresponding predicate, and no more than twice as many applications of any projection.

25.6.9 Count

template<class InputIterator, class T>
constexpr typename iterator_traits<InputIterator>::difference_type
count(InputIterator first, InputIterator last, const T& value);
template<class ExecutionPolicy, class ForwardIterator, class T>
  typename iterator_traits<ForwardIterator>::difference_type
  count(ExecutionPolicy&& exec,
       ForwardIterator first, ForwardIterator last, const T& value);

template<class InputIterator, class Predicate>
  constexpr typename iterator_traits<InputIterator>::difference_type
  count_if(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
  typename iterator_traits<ForwardIterator>::difference_type
  count_if(ExecutionPolicy&& exec,
            ForwardIterator first, ForwardIterator last, Predicate pred);

template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity>
  requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
  constexpr iter_difference_t<I>
  ranges::count(I first, S last, const T& value, Proj proj = {});

template<input_range R, class T, class Proj = identity>
  requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
  constexpr range_difference_t<R>
  ranges::count(R&& r, const T& value, Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
           indirect_unary_predicate<projected<I, Proj>> Pred>
  constexpr iter_difference_t<I>
  ranges::count_if(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity,
           indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
  constexpr range_difference_t<R>
  ranges::count_if(R&& r, Pred pred, Proj proj = {});

Let $E$ be:

1. $*i ==$ value for the overloads with no parameter $pred$ or $proj$;
2. $pred(*i) !=$ false for the overloads with a parameter $pred$ but no parameter $proj$;
3. $invoke(proj, *i) ==$ value for the overloads with a parameter $proj$ but no parameter $pred$;
4. $bool(invoke(pred, invoke(proj, *i)))$ for the overloads with both parameters $proj$ and $pred$.

Effects: Returns the number of iterators $i$ in the range $[\text{first}, \text{last})$ for which $E$ holds.

Complexity: Exactly $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.

§ 25.6.10 Mismatch

```cpp
template<class InputIterator1, class InputIterator2>
  constexpr pair<InputIterator1, InputIterator2>
  mismatch(InputIterator1 first1, InputIterator1 last1,
            InputIterator2 first2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
  pair<ForwardIterator1, ForwardIterator2>
  mismatch(ExecutionPolicy&& exec,
            ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2);

template<class InputIterator1, class InputIterator2, class BinaryPredicate>
  constexpr pair<InputIterator1, InputIterator2>
  mismatch(InputIterator1 first1, InputIterator1 last1,
            InputIterator2 first2, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
  pair<ForwardIterator1, ForwardIterator2>
  mismatch(ExecutionPolicy&& exec,
            ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2, BinaryPredicate pred);
```
template<class InputIterator1, class InputIterator2>
    constexpr pair<InputIterator1, InputIterator2>
mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
          ForwardIterator1 first1, ForwardIterator1 last1,
          ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2,
         class BinaryPredicate>
    constexpr pair<InputIterator1, InputIterator2>
mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2,
             BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
          ForwardIterator1 first1, ForwardIterator1 last1,
          ForwardIterator2 first2, ForwardIterator2 last2,
          BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
    requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
    constexpr ranges::mismatch_result<I1, I2>
ranges::mismatch(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
                     Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2,
         class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
    requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
    constexpr ranges::mismatch_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::mismatch(R1&& r1, R2&& r2, Pred pred = {},
                    Proj1 proj1 = {}, Proj2 proj2 = {});

Let last2 be first2 + (last1 - first1) for the overloads with no parameter last2 or r2.

Let E be:

1. \( !(*(first1 + n) == *(first2 + n)) \) for the overloads with no parameter pred;
2. \( \text{pred}(*(first1 + n), *(first2 + n)) == false \) for the overloads with a parameter pred and no
   parameter proj1;
3. \( !\text{invoke}(\text{pred}, \text{invoke}(\text{proj1}, *(first1 + n)), \text{invoke}(\text{proj2}, *(first2 + n))) \) for the
   overloads with both parameters pred and proj1.

Let N be \( \min(\text{last1} - \text{first1}, \text{last2} - \text{first2}) \).

Returns: \( \{\text{first1} + n, \text{first2} + n\} \), where \( n \) is the smallest integer in \( [0, N) \) such that \( E \) holds, or
\( N \) if no such integer exists.

Complexity: At most \( N \) applications of the corresponding predicate and any projections.
Let:

1. \( \text{last2 be first2 + (last1 - first1)} \) for the overloads with no parameter last2 or r2;
2. \( \text{pred be equal_to()} \) for the overloads with no parameter pred;
3. \( E \) be:
   1. \( \text{pred(*i, *(first2 + (i - first1)))} \) for the overloads with no parameter proj1;
   2. \( \text{invoke(pred, invoke(proj1, *i), invoke(proj2, *(first2 + (i - first1))))} \) for the overloads with parameter proj1.

Returns: If \( \text{last1 - first1} != \text{last2 - first2} \), return false. Otherwise return true if \( E \) holds for every iterator \( i \) in the range \([\text{first1}, \text{last1})\). Otherwise, returns false.

Complexity: If the types of first1, last1, first2, and last2:
1. meet the Cpp17RandomAccessIterator requirements (23.3.5.6) for the overloads in namespace std;
2. pairwise model sized_sentinel_for (23.3.4.8) for the overloads in namespace ranges, and
3. \( \text{last1 - first1} != \text{last2 - first2} \), then no applications of the corresponding predicate and each projection; otherwise,
4. For the overloads with no ExecutionPolicy, at most \( \text{min(last1 - first1, last2 - first2)} \) applications of the corresponding predicate and any projections.
For the overloads with an ExecutionPolicy, $O(\min(\text{last1} - \text{first1}, \text{last2} - \text{first2}))$ applications of the corresponding predicate.

### 25.6.12 Is permutation

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2);

template<class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, BinaryPredicate pred);

template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, BinaryPredicate pred);
```

1. Let last2 be first2 + (last1 - first1) for the overloads with no parameter named last2, and let pred be equal_to{} for the overloads with no parameter pred.

2. **Mandates:** ForwardIterator1 and ForwardIterator2 have the same value type.

3. **Preconditions:** The comparison function is an equivalence relation.

4. **Returns:** If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, last2), beginning with ForwardIterator2 begin, such that equal(first1, last1, begin, pred) returns true; otherwise, returns false.

5. **Complexity:** No applications of the corresponding predicate if ForwardIterator1 and ForwardIterator2 meet the requirements of random access iterators and last1 - first1 != last2 - first2. Otherwise, exactly last1 - first1 applications of the corresponding predicate if equal(first1, last1, first2, last2, pred) would return true; otherwise, at worst $O(N^2)$, where $N$ has the value last1 - first1.

```cpp
template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2, class Proj1 = identity, class Proj2 = identity, indirect_equivalence_relation<projected<I1, Proj1>, projected<I2, Proj2>> Pred = ranges::equal_to>
constexpr bool ranges::is_permutation(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<forward_range R1, forward_range R2, class Proj1 = identity, class Proj2 = identity, indirect_equivalence_relation<projected<iterator_t<R1>, Proj1>, projected<iterator_t<R2>, Proj2>> Pred = ranges::equal_to>
constexpr bool ranges::is_permutation(R1&& r1, R2&& r2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

6. **Returns:** If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, last2), bounded by [pfirst, plast], such that ranges::equal(first1, last1, pfirst, plast, pred, proj1, proj2) returns true; otherwise, returns false.

7. **Complexity:** No applications of the corresponding predicate and projections if:

   - S1 and I1 model sized_sentinel_for<S1, I1>.
   - S2 and I2 model sized_sentinel_for<S2, I2>, and
   - last1 - first1 != last2 - first2.

Otherwise, exactly last1 - first1 applications of the corresponding predicate and projections if ranges::equal(first1, last1, first2, last2, pred, proj1, proj2) would return true; otherwise, at worst $O(N^2)$, where $N$ has the value last1 - first1.
25.6.13 Search

template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
search(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
constexpr ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
        class BinaryPredicate>
ForwardIterator1
search(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    BinaryPredicate pred);

Returns: The first iterator \(i\) in the range \([\text{first1}, \text{last1} - (\text{last2}\text{-}\text{first2}))\) such that for every non-negative integer \(n\) less than \(\text{last2}\text{-}\text{first2}\) the following corresponding conditions hold:
\[
*(i + n) == *(\text{first2} + n), \text{pred}(* (i + n), *(\text{first2} + n)) \neq \text{false}
\]. Returns \text{first1} if \([\text{first2}, \text{last2})\] is empty, otherwise returns \text{last1} if no such iterator is found.

Complexity: At most \((\text{last1} - \text{first1}) \times (\text{last2} - \text{first2})\) applications of the corresponding predicate.

template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2,
        sentinel_for<I2> S2, class Pred = ranges::equal_to,
        class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr subrange<I1>
ranges::search(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
    Proj1 proj1 = {}, Proj2 proj2 = {});

template<forward_range R1, forward_range R2, class Pred = ranges::equal_to,
        class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_subrange_t<R1>
ranges::search(R1&& r1, R2&& r2, Pred pred = {},
    Proj1 proj1 = {}, Proj2 proj2 = {});

Returns:
\[\{i, i + (\text{last2} - \text{first2})\}\], where \(i\) is the first iterator in the range \([\text{first1}, \text{last1} - (\text{last2} - \text{first2}))\) such that for every non-negative integer \(n\) less than \text{last2} - \text{first2}\) the condition
\[
\text{bool}((\text{invoke}((\text{pred}, \text{invoke}((\text{proj1}, *(i + n)), \text{invoke}((\text{proj2}, *(\text{first2} + n)))))) \neq \text{true}
\].

Returns \{\text{last1}, \text{last1}\} if no such iterator exists.

Complexity: At most \((\text{last1} - \text{first1}) \times (\text{last2} - \text{first2})\) applications of the corresponding predicate and projections.
Mandates: The type Size is convertible to an integral type (7.3.8, 11.4.7).

Returns: The first iterator \( i \) in the range \([\text{first}, \text{last}-\text{count})\) such that for every non-negative integer \( n \) less than \( \text{count} \) the following corresponding conditions hold: \(* (i + n) == \text{value}, \text{pred}(* (i + n), \text{value}) != \text{false}\). Returns last if no such iterator is found.

Complexity: At most last - first applications of the corresponding predicate.

Returns: \( \{i, i + \text{count}\} \) where \( i \) is the first iterator in the range \([\text{first}, \text{last} - \text{count})\) such that for every non-negative integer \( n \) less than \( \text{count} \), the following condition holds: \( \text{invoke}(\text{pred}, \text{invoke}(\text{proj}, * (i + n)), \text{value})\). Returns \( \{\text{last}, \text{last}\} \) if no such iterator is found.

Complexity: At most last - first applications of the corresponding predicate and projection.

Effects: Equivalent to: return \( \text{searcher}(\text{first}, \text{last}).\text{first} \).

Remarks: Searcher need not meet the \texttt{Cpp17CopyConstructible} requirements.

### 25.7 Mutating sequence operations

#### 25.7.1 Copy

```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator copy(InputIterator first, InputIterator last, OutputIterator result);
```

```cpp
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::copy_result<I, O> ranges::copy(I first, S last, O result);
```

Let \( N \) be last - first.
Preconditions: result is not in the range \([\text{first}, \text{last})\).

Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + N)\) starting from \text{first} and proceeding to \text{last}. For each non-negative integer \(n < N\), performs \(*(\text{result} + n) = *(\text{first} + n)\).

Returns:
- result + N for the overload in namespace std.
- \{last, result + N\} for the overloads in namespace ranges.

Complexity: Exactly \(N\) assignments.

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 copy(ExecutionPolicy&& policy,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result);
```

Preconditions: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) do not overlap.

Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\). For each non-negative integer \(n < (\text{last} - \text{first})\), performs \(*(\text{result} + n) = *(\text{first} + n)\).

Returns: result + (last - first).

Complexity: Exactly last - first assignments.

```
template<class InputIterator, class Size, class OutputIterator>
constexpr OutputIterator copy_n(InputIterator first, Size n,
OutputIterator result);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class Size, class ForwardIterator2>
ForwardIterator2 copy_n(ExecutionPolicy&& exec,
ForwardIterator1 first, Size n,
ForwardIterator2 result);
```

```
template<input_iterator I, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr OutputIterator copy_n(I first, iter_difference_t<I> n, O result);
```

Let \(N\) be \(\max(0, n)\).

Mandates: The type Size is convertible to an integral type (7.3.8, 11.4.7).

Effects: For each non-negative integer \(i < N\), performs \(*(\text{result} + i) = *(\text{first} + i)\).

Returns:
- result + N for the overloads in namespace std.
- \{first + N, result + N\} for the overload in namespace ranges.

Complexity: Exactly \(N\) assignments.

```
template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator copy_if(InputIterator first, InputIterator last,
OutputIterator result, Predicate pred);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Predicate>
ForwardIterator2 copy_if(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, Predicate pred);
```

```
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
constexpr OutputIterator copy_if(I first, S last, O result, Pred pred, Proj proj = {});
```

§ 25.7.1
Let $E$ be:

\begin{align}
\text{(15.1)} & \quad \text{bool}(\text{pred}(\ast i)) \quad \text{for the overloads in namespace std;} \\
\text{(15.2)} & \quad \text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, \ast i))) \quad \text{for the overloads in namespace ranges,}
\end{align}

and $N$ be the number of iterators $i$ in the range $[\text{first}, \text{last})$ for which the condition $E$ holds.

**Preconditions:** The ranges $[\text{first}, \text{last})$ and $[\text{result}, \text{result} + (\text{last} - \text{first}))$ do not overlap.

**Note:** For the overload with an `ExecutionPolicy`, there may be a performance cost if `iterator_traits<ForwardIterator1>::value_type` is not `Cpp17MoveConstructible` (Table 28). — end note

**Effects:** Copies all of the elements referred to by the iterator $i$ in the range $[\text{first}, \text{last})$ for which $E$ is true.

**Returns:**

\begin{align}
\text{(18.1)} & \quad \text{result} + N \quad \text{for the overloads in namespace std.} \\
\text{(18.2)} & \quad \{\text{last}, \text{result} + N\} \quad \text{for the overloads in namespace ranges.}
\end{align}

**Complexity:** Exactly $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.

**Remarks:** Stable (16.5.5.8).

\begin{verbatim}
template<class BidirectionalIterator1, class BidirectionalIterator2>
constexpr BidirectionalIterator2
copy_backward(BidirectionalIterator1 first, 
BidirectionalIterator1 last, 
BidirectionalIterator2 result);
\end{verbatim}

\begin{verbatim}
template<bidirectional_iterator I1, sentinel_for<I1> S1, bidirectional_iterator I2>
requires indirectly_copyable<I1, I2>
constexpr ranges::copy_backward_result<I1, I2>
ranges::copy_backward(I1 first, S1 last, I2 result);
\end{verbatim}

\begin{verbatim}
template<bidirectional_range R, bidirectional_iterator I>
requires indirectly_copyable<iterator_t<R>, I>
constexpr ranges::copy_backward_result<borrowed_iterator_t<R>, I>
ranges::copy_backward(R&& r, I result);
\end{verbatim}

Let $N$ be $\text{last} - \text{first}$.

**Preconditions:** result is not in the range $[\text{first}, \text{last})$.

**Effects:** Copies elements in the range $[\text{first}, \text{last})$ into the range $[\text{result} - N, \text{result})$ starting from $\text{last} - 1$ and proceeding to $\text{first}$\footnote{\texttt{copy\_backward} should be used instead of \texttt{copy} when $\text{last}$ is in the range $[\text{result} - N, \text{result})$.}. For each positive integer $n \leq N$, performs $*($result $- n) = *($last $- n)$.

**Returns:**

\begin{align}
\text{(24.1)} & \quad \text{result} - N \quad \text{for the overload in namespace std.} \\
\text{(24.2)} & \quad \{\text{last}, \text{result} - N\} \quad \text{for the overloads in namespace ranges.}
\end{align}

**Complexity:** Exactly $N$ assignments.

### 25.7.2 Move [alg.move]

\begin{verbatim}
template<class InputIterator, class OutputIterator>
constexpr OutputIterator move(InputIterator first, InputIterator last, 
OutputIterator result);
\end{verbatim}

\begin{verbatim}
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_movable<I, O>
constexpr ranges::move_result<I, O>
ranges::move(I first, S last, O result);
\end{verbatim}
 Let $E$ be
  \begin{align}
  (1.1) & \quad \text{std::move(*(first + n)) for the overload in namespace std;} \\
  (1.2) & \quad \text{ranges::iter_move(first + n) for the overloads in namespace ranges.}
  \end{align}

Let $N$ be last - first.

**Preconditions:** result is not in the range $[\text{first, last})$.

**Effects:** Moves elements in the range $[\text{first, last})$ into the range $[\text{result, result + N})$ starting from first and proceeding to last. For each non-negative integer $n < N$, performs $\text{*}(\text{result + n}) = E$.

**Returns:**
  \begin{align}
  (4.1) & \quad \text{result + N for the overload in namespace std} \\
  (4.2) & \quad \{\text{last, result + N}\} for the overloads in namespace ranges.
  \end{align}

**Complexity:** Exactly $N$ assignments.

Let $E$ be
  \begin{align}
  (11.1) & \quad \text{std::move(*(last - n)) for the overload in namespace std;} \\
  (11.2) & \quad \text{ranges::iter_move(last - n) for the overloads in namespace ranges.}
  \end{align}

Let $N$ be last - first.

**Preconditions:** The ranges $[\text{first, last})$ and $[\text{result, result + N})$ do not overlap.

**Effects:** Moves elements in the range $[\text{first, last})$ into the range $[\text{result, result + N})$. For each non-negative integer $n < N$, performs $\text{*}(\text{result + n}) = \text{std::move(*}(\text{first + n}))$.

**Returns:**
  \begin{align}
  (14.1) & \quad \text{result - N for the overload in namespace std} \\
  (14.2) & \quad \{\text{last, result - N}\} for the overloads in namespace ranges.
  \end{align}

**Complexity:** Exactly $N$ assignments.

move_backward should be used instead of move when last is in the range $[\text{result - N}, \text{result})$. 

§ 25.7.2
**Complexity:** Exactly \( N \) assignments.

### 25.7.3 Swap

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator2
swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
swap_ranges(ExecutionPolicy&& exec,
            ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2);
```

```cpp
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2>
requires indirectly_swappable<I1, I2>
constexpr ranges::swap_ranges_result<I1, I2>
ranges::swap_ranges(I1 first1, S1 last1, I2 first2, S2 last2);
```

```cpp
template<input_range R1, input_range R2>
requires indirectly_swappable<iterator_t<R1>, iterator_t<R2>>
constexpr ranges::swap_ranges_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::swap_ranges(R1&& r1, R2&& r2);
```

Let:

1. (1.1) \( \text{last2 be first2 + (last1 - first1)} \) for the overloads with no parameter named \( \text{last2} \);
2. (1.2) \( M \) be \( \min(\text{last1 - first1}, \text{last2 - first2}) \).

**Preconditions:** The two ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) do not overlap. For the overloads in namespace \( \text{std} \), \((\ast\text{first1} + n)\) is swappable with \((16.5.3.2) \ast(\text{first2} + n)\).

**Effects:** For each non-negative integer \( n < M \) performs:

1. (3.1) \( \text{swap}(\ast\text{first1} + n), \ast(\text{first2} + n) \) for the overloads in namespace \( \text{std} \);
2. (3.2) \( \text{ranges::iter_swap(first1} + n, \text{first2} + n) \) for the overloads in namespace \( \text{ranges} \).

**Returns:**

1. (4.1) \( \text{last2 for the overloads in namespace } \text{std} \).
2. (4.2) \( \{\text{first1} + M, \text{first2} + M\} \) for the overloads in namespace \( \text{ranges} \).

**Complexity:** Exactly \( M \) swaps.

### 25.7.4 Transform

```cpp
template<class InputIterator, class OutputIterator, class UnaryOperation>
constexpr OutputIterator
transform(InputIterator first1, InputIterator last1,
          OutputIterator result, UnaryOperation op);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class UnaryOperation>
ForwardIterator2
transform(ExecutionPolicy&& exec,
          ForwardIterator1 first1, ForwardIterator1 last1,
          ForwardIterator2 result, UnaryOperation op);
```

**Preconditions:** \( a \) and \( b \) are dereferenceable. \( \ast a \) is swappable with \((16.5.3.2) \ast b\).

**Effects:** As if by \( \text{swap}(\ast a, \ast b) \).
Let:

1. last2 be first2 + (last1 - first1) for the overloads with parameter first2 but no parameter last2;
2. \(N\) be last1 - first1 for unary transforms, or \(\min(last1 - first1, last2 - first2)\) for binary transforms;
3. \(E\) be
   1. \(op(*(first1 + (i - result)))\) for unary transforms defined in namespace std;
   2. \(binary\_op(*(first1 + (i - result)), *(first2 + (i - result)))\) for binary transforms defined in namespace std;
   3. invoke(op, invoke(proj, *(first1 + (i - result)))) for unary transforms defined in namespace ranges;
   4. invoke(binary\_op, invoke(proj1, *(first1 + (i - result))), invoke(proj2, *(first2 + (i - result)))) for binary transforms defined in namespace ranges.

2. **Preconditions:** \(op\) and \(binary\_op\) do not invalidate iterators or subranges, nor modify elements in the ranges
   1. \([first1, first1 + N]\),
   2. \([first2, first2 + N]\), and
   3. \([result, result + N]\).\(^{233}\)

---

\(^{233}\) The use of fully closed ranges is intentional.
Effects: Assigns through every iterator \( i \) in the range \([\text{result}, \text{result} + N)\) a new corresponding value equal to \( E \).

Returns:

\( (1.1) \) \( \text{result} + N \) for the overloads defined in namespace std.

\( (1.2) \) \{\( \text{first1} + N, \text{result} + N \)\} for unary transforms defined in namespace ranges.

\( (1.3) \) \{\( \text{first1} + N, \text{first2} + N, \text{result} + N \)\} for binary transforms defined in namespace ranges.

Complexity: Exactly \( N \) applications of op or binary_op, and any projections. This requirement also applies to the overload with an ExecutionPolicy.

Remarks: result may be equal to first1 or first2.

25.7.5 Replace

[alg.replace]

\[ \text{template<class ForwardIterator, class T>} \]
\[ \text{constexpr void replace(ForwardIterator first, ForwardIterator last,} \]
\[ \text{const T& old_value, const T& new_value);} \]
\[ \text{template<class ExecutionPolicy, class ForwardIterator, class T>} \]
\[ \text{void replace(ExecutionPolicy&& exec,} \]
\[ \text{ForwardIterator first, ForwardIterator last,} \]
\[ \text{const T& old_value, const T& new_value);} \]
\[ \text{template<class ForwardIterator, class Predicate, class T>} \]
\[ \text{constexpr void replace_if(ForwardIterator first, ForwardIterator last,} \]
\[ \text{Predicate pred, const T& new_value);} \]
\[ \text{template<class ExecutionPolicy, class ForwardIterator, class Predicate, class T>} \]
\[ \text{void replace_if(ExecutionPolicy&& exec,} \]
\[ \text{ForwardIterator first, ForwardIterator last,} \]
\[ \text{Predicate pred, const T& new_value);} \]
\[ \text{template<input_iterator I, sentinel_for<I> S, class T1, class T2, class Proj = identity} \]
\[ \text{requires indirectly_writable<I, const T2&> \&\&} \]
\[ \text{indirect_binary_predicate<ranges::equal_to, projected<I, Proj>>, const T1*>} \]
\[ \text{constexpr I} \]
\[ \text{ranges::replace(I first, S last, const T1& old_value, const T2& new_value, Proj proj = {});} \]
\[ \text{template<input_range R, class T1, class T2, class Proj = identity} \]
\[ \text{requires indirectly_writable<iterator_t<R>, const T2&> \&\&} \]
\[ \text{indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>>, const T1*>} \]
\[ \text{constexpr borrowed_iterator_t<R>} \]
\[ \text{ranges::replace(R&& r, const T1& old_value, const T2& new_value, Proj proj = {});} \]
\[ \text{template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity} \]
\[ \text{indirect Unary predicate<projected<1, Proj>>, Pred>} \]
\[ \text{requires indirectly_writable<I, const T&>} \]
\[ \text{constexpr I} \]
\[ \text{ranges::replace_if(I first, S last, Pred pred, const T& new_value, Proj proj = {});} \]
\[ \text{template<input_range R, class T, class Proj = identity} \]
\[ \text{indirect Unary predicate<projected<iterator_t<R>, Proj>>, Pred>} \]
\[ \text{requires indirectly_writable<iterator_t<R>, const T&>} \]
\[ \text{constexpr borrowed_iterator_t<R>;} \]
\[ \text{ranges::replace_if(R&& r, Pred pred, const T& new_value, Proj proj = {});} \]

Let \( E \) be

\[ \begin{align*}
(1.1) & \quad \text{bool(*i == old_value) for replace;} \\
(1.2) & \quad \text{bool(pred(*i)) for replace_if;} \\
(1.3) & \quad \text{bool(invoke(proj, *i) == old_value) for ranges::replace;} \\
(1.4) & \quad \text{bool(invoke(pred, invoke(proj, *i))) for ranges::replace_if.}
\end{align*} \]

Mandates: new_value is writable (23.3.1) to first.

Effects: Substitutes elements referred by the iterator \( i \) in the range \([\text{first}, \text{last})\) with new_value, when \( E \) is true.

Returns: last for the overloads in namespace ranges.

Complexity: Exactly last - first applications of the corresponding predicate and any projection.
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
replace_copy(InputIterator first, InputIterator last, OutputIterator result,
const T& old_value, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
replace_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result,
const T& old_value, const T& new_value);

template<class InputIterator, class OutputIterator, class Predicate, class T>
constexpr OutputIterator
replace_copy_if(InputIterator first, InputIterator last, OutputIterator result,
Predicate pred, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Predicate, class T>
ForwardIterator2
replace_copy_if(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result,
Predicate pred, const T& new_value);

template<input_iterator I, sentinel_for<I> S, class T1, class T2, output_iterator<const T2&> O,
class Proj = identity>
requires indirectly_copyable<I, O> &&
indirect_binary_predicate<ranges::equal_to, projected<I, Proj>>, const T1>>
constexpr ranges::replace_copy_result<I, O>
ranges::replace_copy(I first, S last, O result, const T1& old_value, const T2& new_value,
Proj proj = {});

template<input_range R, class T1, class T2, output_iterator<const T2&> O,
class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>>, const T1>>
constexpr ranges::replace_copy_result<borrowed_iterator_t<R>, O>
ranges::replace_copy(R&& r, O result, const T1& old_value, const T2& new_value,
Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class T, output_iterator<const T&> O,
class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
constexpr ranges::replace_copy_if_result<I, O>
ranges::replace_copy_if(I first, S last, O result, Pred pred, const T& new_value,
Proj proj = {});

template<input_range R, class T, output_iterator<const T&> O, class Proj = identity, indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::replace_copy_if_result<borrowed_iterator_t<R>, O>
ranges::replace_copy_if(R&& r, O result, Pred pred, const T& new_value,
Proj proj = {});

Let $E$ be

- bool(*(first + (i - result)) == old_value) for replace_copy;
- bool(pred(*(first + (i - result)))) for replace_copy_if;
- bool(invoke(proj, *(first + (i - result)))) == old_value) for ranges::replace_copy;
- bool(invoke(pred, invoke(proj, *(first + (i - result)))))) for ranges::replace_copy_if.

Mandates: The results of the expressions *first and new_value are writable (23.3.1) to result.

Preconditions: The ranges [first, last) and [result, result + (last - first)) do not overlap.
Effects: Assigns through every iterator \(i\) in the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\) a new corresponding value

- \(\text{new\_value}\) if \(E\) is true or
- \(* (\text{first} + (i - \text{result}))\) otherwise.

Returns:
- \(\text{result} + (\text{last} - \text{first})\) for the overloads in namespace std.
- \(\{\text{last}, \text{result} + (\text{last} - \text{first})\}\) for the overloads in namespace ranges.

Complexity: Exactly \(\text{last} - \text{first}\) applications of the corresponding predicate and any projection.

25.7.6 Fill

```
template<class ForwardIterator, class T>
constexpr void fill(ForwardIterator first, ForwardIterator last, const T& value);
```

```
template<class ExecutionPolicy, class ForwardIterator, class T>
void fill(ExecutionPolicy&& exec,
          ForwardIterator first, ForwardIterator last, const T& value);
```

```
template<class OutputIterator, class Size, class T>
constexpr OutputIterator fill_n(OutputIterator first, Size n, const T& value);
```

```
template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator fill_n(ExecutionPolicy&& exec,
                       ForwardIterator first, Size n, const T& value);
```

```
template<class T, output_iterator<const T&> O, sentinel_for<O> S>
constexpr O ranges::fill(O first, S last, const T& value);
```

```
template<class T, output_range<const T&> R>
constexpr borrowed_iterator_t<R> ranges::fill(R&& r, const T& value);
```

```
template<class T, output_iterator<const T&> O>
constexpr O ranges::fill_n(O first, iter_difference_t<O> n, const T& value);
```

Let \(N\) be \(\max(0, n)\) for the \(\text{fill\_n}\) algorithms, and \(\text{last} - \text{first}\) for the \(\text{fill}\) algorithms.

Mandates: The expression \(\text{value}\) is writable (23.3.1) to the output iterator. The type \(\text{Size}\) is convertible to an integral type (7.3.8, 11.4.7).

Effects: Assigns value through all the iterators in the range \([\text{first}, \text{first} + N)\).

Returns: \(\text{first} + N\).

Complexity: Exactly \(N\) assignments.

25.7.7 Generate

```
template<class ForwardIterator, class Generator>
constexpr void generate(ForwardIterator first, ForwardIterator last, Generator gen);
```

```
template<class ExecutionPolicy, class ForwardIterator, class Generator>
void generate(ExecutionPolicy&& exec,
              ForwardIterator first, ForwardIterator last, Generator gen);
```

```
template<class OutputIterator, class Size, class Generator>
constexpr OutputIterator generate_n(OutputIterator first, Size n, Generator gen);
```

```
template<class ExecutionPolicy, class ForwardIterator, class Size, class Generator>
ForwardIterator generate_n(ExecutionPolicy&& exec,
                            ForwardIterator first, Size n, Generator gen);
```

```
template<input_or_output_iterator O, sentinel_for<O> S, copy_constructible F>
requires invocable<F&> &\& indirectly_writable<O, invoke_result_t<F&>>
constexpr O ranges::generate(O first, S last, F gen);
```

```
template<class R, copy_constructible F>
requires invocable<F&> &\& output_range<R, invoke_result_t<F&>>
constexpr borrowed_iterator_t<R> ranges::generate(R&& r, F gen);
```

§ 25.7.7
template<input_or_output_iterator O, copy_constructible F>
requires invocable<F&> && indirectly_writable<O, invoke_result_t<F&>>
constexpr O ranges::generate_n(O first, iter_difference_t<O> n, F gen);

Let \( N \) be \( \max(0, n) \) for the \texttt{generate_n} algorithms, and \( \text{last} - \text{first} \) for the \texttt{generate} algorithms.

\textbf{Mandates:} Size is convertible to an integral type (7.3.8, 11.4.7).

\textbf{Effects:} Assigns the result of successive evaluations of \texttt{gen()} through each iterator in the range \([\text{first}, \text{first} + N)\).

\textbf{Returns:} \( \text{first} + N \).

\textbf{Complexity:} Exactly \( N \) evaluations of \texttt{gen()} and assignments.

### 25.7.8 Remove

\texttt{template<class ForwardIterator, class T>}
\begin{verbatim}
constexpr ForwardIterator remove(ForwardIterator first, ForwardIterator last,
    const T& value);
\end{verbatim}

\texttt{template<class ExecutionPolicy, class ForwardIterator, class T>}
\begin{verbatim}
ForwardIterator remove(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    const T& value);
\end{verbatim}

\texttt{template<class ForwardIterator, class Predicate>}
\begin{verbatim}
constexpr ForwardIterator remove_if(ForwardIterator first, ForwardIterator last,
    Predicate pred);
\end{verbatim}

\texttt{template<class ExecutionPolicy, class ForwardIterator, class Predicate>}
\begin{verbatim}
ForwardIterator remove_if(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    Predicate pred);
\end{verbatim}

\texttt{template<permutable I, sentinel_for<I> S, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr subrange<I> ranges::remove(I first, S last, const T& value, Proj proj = {});
}

\texttt{template<forward_range R, class T, class Proj = identity>
requires permutable<iterator_t<R>> &&
    indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr borrowed_subrange_t<R>
ranges::remove(R&& r, const T& value, Proj proj = {});
}

\texttt{template<permutable I, sentinel_for<I> S, class Proj = identity,
    indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirect_unary_predicate<projected<iterator_t<R>, Proj>, Pred>
constexpr subrange<I> ranges::remove_if(I first, S last, Pred pred, Proj proj = {});
}

\texttt{template<forward_range R, class Proj = identity,
    indirect_unary_predicate<projected<iterator_t<R>, Proj>, Pred>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R>
ranges::remove_if(R&& r, Pred pred, Proj proj = {});
}

Let \( E \) be

\begin{enumerate}
\item \( \text{bool}(\text{*i == value}) \) for \texttt{remove};
\item \( \text{bool}(\text{pred}(\text{*i})) \) for \texttt{remove_if};
\item \( \text{bool}(\text{invoke(proj, *i) == value}) \) for \texttt{ranges::remove};
\item \( \text{bool}(\text{invoke(pred, invoke(proj, *i)))} \) for \texttt{ranges::remove_if}.
\end{enumerate}

\textbf{Preconditions:} For the algorithms in namespace \texttt{std}, the type of \texttt{*first} meets the \texttt{Cpp17MoveAssignable} requirements (Table 30).

\textbf{Effects:} Eliminates all the elements referred to by iterator \texttt{i} in the range \([\text{first}, \text{last})\) for which \( E \) holds.

\textbf{Returns:} Let \( j \) be the end of the resulting range. Returns:

\begin{enumerate}
\item \( j \) for the overloads in namespace \texttt{std}.
\item \( \{j, \text{last}\} \) for the overloads in namespace \texttt{ranges}.
\end{enumerate}
Complexity: Exactly last - first applications of the corresponding predicate and any projection.

Remarks: Stable (16.5.5.8).

[Note: Each element in the range [ret, last), where ret is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range. — end note]

template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
remove_copy(InputIterator first, InputIterator last,
OutputIterator result, const T& value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class T>
ForwardIterator2
remove_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, const T& value);

template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator
remove_copy_if(InputIterator first, InputIterator last,
OutputIterator result, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Predicate>
ForwardIterator2
remove_copy_if(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, Predicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class T,
class Proj = identity>
requires indirectly_copyable<I, O> &&
indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr ranges::remove_copy_result<I, O>
ranges::remove_copy(I first, S last, O result, const T& value, Proj proj = {});

template<input_range R, weakly_incrementable O, class T, class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr ranges::remove_copy_result<borrowed_iterator_t<R>, O>
ranges::remove_copy(R&& r, O result, const T& value, Proj proj = {});

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O,
class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
constexpr ranges::remove_copy_if_result<I, O>
ranges::remove_copy_if(I first, S last, O result, Pred pred, Proj proj = {});

template<input_range R, weakly_incrementable O, class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::remove_copy_if_result<borrowed_iterator_t<R>, O>
ranges::remove_copy_if(R&& r, O result, Pred pred, Proj proj = {});

Let E be

- bool(*i == value) for remove_copy;
- bool(pred(*i)) for remove_copy_if;
- bool(invoke(proj, *i) == value) for ranges::remove_copy;
- bool(invoke(pred, invoke(proj, *i))) for ranges::remove_copy_if.

Let N be the number of elements in [first, last) for which E is false.

Mandates: *first is writable (23.3.1) to result.

Preconditions: The ranges [first, last) and [result, result + (last - first)) do not overlap.

[Note: For the overloads with an ExecutionPolicy, there may be a performance cost if iterator_traits<ForwardIterator> type does not meet the Cpp17MoveConstructible (Table 28) requirements. — end note]
25.7.9 Unique

Effects: Copies all the elements referred to by the iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( E \) is false.

Returns:
- \( \text{result} + N \), for the algorithms in namespace std.
- \( \{\text{last}, \text{result} + N\} \), for the algorithms in namespace ranges.

Complexity: Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate and any projection.

Remarks: Stable (16.5.5.8).

### [alg.unique]

```cpp
template<class ForwardIterator>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator unique(ExecutionPolicy&& exec,
                        ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last,
                                 BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator unique(ExecutionPolicy&& exec,
                       ForwardIterator first, ForwardIterator last,
                       BinaryPredicate pred);

template<permutable I, sentinel_for<I> S, class Proj = identity,
          indirect_equivalence_relation<projected<I, Proj>> C = ranges::equal_to>
constexpr subrange<I> ranges::unique(I first, S last, C comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
          indirect_equivalence_relation<iterator_t<R>, Proj>> C = ranges::equal_to>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R>
ranges::unique(R&& r, C comp = {}, Proj proj = {});
```

Let \( \text{pred} \) be \( \text{equal\_to}\) for the overloads with no parameter \( \text{pred} \), and let \( E \) be

1. \( \text{bool} (\text{pred}(* (i - 1), *i)) \) for the overloads in namespace std;
2. \( \text{bool} (\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, *(i - 1)), \text{invoke}(\text{proj}, *i))) \) for the overloads in namespace ranges.

Preconditions: For the overloads in namespace std, \( \text{pred} \) is an equivalence relation and the type of \( *\text{first} \) meets the Cpp17MoveAssignable requirements (Table 30).

Effects: For a nonempty range, eliminates all but the first element from every consecutive group of equivalent elements referred to by the iterator \( i \) in the range \([\text{first} + 1, \text{last})\) for which \( E \) is true.

Returns: Let \( j \) be the end of the resulting range. Returns:

1. \( j \) for the overloads in namespace std.
2. \( \{j, \text{last}\} \) for the overloads in namespace ranges.

Complexity: For nonempty ranges, exactly \( (\text{last} - \text{first}) - 1 \) applications of the corresponding predicate and no more than twice as many applications of any projection.
template<class InputIterator, class OutputIterator, class BinaryPredicate>
constexpr OutputIterator
unique_copy(InputIterator first, InputIterator last,
OutputIterator result, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
ForwardIterator2
unique_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, BinaryPredicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Proj = identity, indirect_equivalence_relation<projected<I, Proj>> C = ranges::equal_to>
requires indirectly_copyable<I, O> &&
(forward_iterator<I> ||
(indirectly_copyable_storable<I, O>))
constexpr ranges::unique_copy_result<I, O>
ranges::unique_copy(I first, S last, O result, C comp = {}, Proj proj = {});

template<input_range R, weakly_incrementable O, class Proj = identity, indirect_equivalence_relation<projected<iterator_t<R>, Proj>> C = ranges::equal_to>
requires indirectly_copyable<iterator_t<R>, O> &&
(forward_iterator<iterator_t<R>> ||
(indirectly_copyable_storable<iterator_t<R>, O>))
constexpr ranges::unique_copy_result<borrowed_iterator_t<R>, O>
ranges::unique_copy(R&& r, O result, C comp = {}, Proj proj = {});

Let pred be equal_to{} for the overloads in namespace std with no parameter pred, and let E be
— bool(pred(*i, *(i - 1))) for the overloads in namespace std;
— bool(invoke(comp, invoke(proj, *i), invoke(proj, *(i - 1)))) for the overloads in name-
space ranges.

Mandates: *first is writable (23.3.1) to result.

Preconditions:
— The ranges [first, last) and [result, result+(last-first)) do not overlap.
— For the overloads in namespace std:
  — The comparison function is an equivalence relation.
  — For the overloads with no ExecutionPolicy, let T be the value type of InputIterator. If
    InputIterator meets the Cpp17ForwardIterator requirements, then there are no additional re-
    quirements for T. Otherwise, if OutputIterator meets the Cpp17ForwardIterator requirements and
    its value type is the same as T, then T meets the Cpp17CopyAssignable (Table 31) requirements. Oth-
    erwise, T meets both the Cpp17CopyConstructible (Table 29) and Cpp17CopyAssignable
    requirements. [Note: For the overloads with an ExecutionPolicy, there may be a performance cost if the value type
    of ForwardIterator1 does not meet both the Cpp17CopyConstructible and Cpp17CopyAssignable
    requirements. — end note]

Effects: Copies only the first element from every consecutive group of equal elements referred to by the iterator
i in the range [first, last) for which E holds.

Returns:
— result + N for the overloads in namespace std.
— {last, result + N} for the overloads in namespace ranges.

Complexity: Exactly last - first - 1 applications of the corresponding predicate and no more than twice
as many applications of any projection.

25.7.10 Reverse [alg.reverse]

template<class BidirectionalIterator>

constexpr void reverse(BidirectionalIterator first, BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void reverse(ExecutionPolicy&& exec,
             BidirectionalIterator first, BidirectionalIterator last);

template<bidirectional_iterator I, sentinel_for<I> S>
requires permutable<I>
constexpr I ranges::reverse(I first, S last);

template<bidirectional_iterator_t<R>>
requires permutable<iterator_t<R>>
constexpr borrowed_iterator_t<R> ranges::reverse(R&& r);

1 Preconditions: For the overloads in namespace std, BidirectionalIterator meets the Cpp17ValueSwappable requirements (16.5.3.2).

2 Effects: For each non-negative integer i < \((last - first) / 2\) applies std::iter_swap, or ranges::iter_swap for the overloads in namespace ranges, to all pairs of iterators first + i, (last - i) - 1.

3 Returns: last for the overloads in namespace ranges.

4 Complexity: Exactly \((last - first) / 2\) swaps.

template<class BidirectionalIterator, class OutputIterator>
constexpr OutputIterator
reverse_copy(BidirectionalIterator first, BidirectionalIterator last,
            OutputIterator result);

template<class ExecutionPolicy, class BidirectionalIterator, class ForwardIterator>
ForwardIterator
reverse_copy(ExecutionPolicy&& exec,
             BidirectionalIterator first, BidirectionalIterator last,
             ForwardIterator result);

5 Let \(N\) be last - first.

6 Preconditions: The ranges \([first, last)\) and \([result, result + N)\) do not overlap.

7 Effects: Copies the range \([first, last)\) to the range \([result, result + N)\) such that for every non-negative integer \(i < N\) the following assignment takes place: \(*(result + N - 1 - i) = *(first + i)\).

8 Returns:

   8.1 \(\{-result + N\}\) for the overloads in namespace std.

   8.2 \{last, result + N\} for the overloads in namespace ranges.

9 Complexity: Exactly \(N\) assignments.

25.7.11 Rotate

\[\text{alg.rotate}\]

template<class ForwardIterator>
constexpr ForwardIterator
rotate(ForwardIterator first, ForwardIterator middle, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
rotate(ExecutionPolicy&& exec,
       ForwardIterator first, ForwardIterator middle, ForwardIterator last);
```cpp
template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::rotate(I first, I middle, S last);

1 | Preconditions: \([first, middle)\) and \([middle, last)\) are valid ranges. For the overloads in namespace std, ForwardIterator meets the Cpp17ValueSwappable requirements (16.5.3.2), and the type of \(*first\) meets the Cpp17MoveConstructible (Table 28) and Cpp17MoveAssignable (Table 30) requirements.

2 | Effects: For each non-negative integer \(i < (last - first)\), places the element from the position \(first + i\) into position \(first + (i + (last - middle)) \% (last - first)\). [Note: This is a left rotate. — end note]

3 | Returns:
   - \(first + (last - middle)\) for the overloads in namespace std.
   - \{first + (last - middle), last\} for the overload in namespace ranges.

4 | Complexity: At most \(last - first\) swaps.

```
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Gen>
   requires (forward_iterator<I> || random_access_iterator<O>) &&
   indirectly_copyable<I, O> &&
   uniform_random_bit_generator<remove_reference_t<Gen>>
O ranges::sample(I first, S last, O out, iter_difference_t<I> n, Gen&& g);

template<input_range R, weakly_incrementable O, class Gen>
   requires (forward_range<R> || random_access_iterator<O>) &&
   indirectly_copyable<iterator_t<R>, O> &&
   uniform_random_bit_generator<remove_reference_t<Gen>>
O ranges::sample(R&& r, O out, range_difference_t<R> n, Gen&& g);

1 Mandates: For the overload in namespace std, Distance is an integer type and *first is writable (23.3.1) to out.

2 Preconditions: out is not in the range [first, last). For the overload in namespace std:
(2.1) — PopulationIterator meets the Cpp17InputIterator requirements (23.3.5.2).
(2.2) — SampleIterator meets the Cpp17OutputIterator requirements (23.3.5.3).
(2.3) — SampleIterator meets the Cpp17RandomAccessIterator requirements (23.3.5.6) unless PopulationIterator meets the Cpp17ForwardIterator requirements (23.3.5.4).
(2.4) — remove_reference_t<UniformRandomBitGenerator> meets the requirements of a uniform random bit generator type (26.6.2.3).

3 Effects: Copies min(last - first, n) elements (the sample) from [first, last) (the population) to out such that each possible sample has equal probability of appearance. [Note: Algorithms that obtain such effects include selection sampling and reservoir sampling. — end note]

4 Returns: The end of the resulting sample range.

5 Complexity: $O((last - first)$.

6 Remarks:
(6.1) — For the overload in namespace std, stable if and only if PopulationIterator meets the Cpp17ForwardIterator requirements. For the first overload in namespace ranges, stable if and only if I models forward_iterator.
(6.2) — To the extent that the implementation of this function makes use of random numbers, the object g serves as the implementation’s source of randomness.

### 25.7.13 Shuffle

template<class RandomAccessIterator, class UniformRandomBitGenerator>
void shuffle(RandomAccessIterator first,
            RandomAccessIterator last,
            UniformRandomBitGenerator&& g);

template<random_access_iterator I, sentinel_for<I> S, class Gen>
   requires permutable<I> &&
   uniform_random_bit_generator<remove_reference_t<Gen>>
I ranges::shuffle(I first, S last, Gen&& g);

template<random_access_range R, class Gen>
   requires permutable<iterator_t<R>> &&
   uniform_random_bit_generator<remove_reference_t<Gen>>
borrowed_iterator_t<R> ranges::shuffle(R&& r, Gen&& g);

1 Preconditions: For the overload in namespace std:
(1.1) — RandomAccessIterator meets the Cpp17ValueSwappable requirements (16.5.3.2).
(1.2) — The type remove_reference_t<UniformRandomBitGenerator> meets the uniform random bit generator (26.6.2.3) requirements.

2 Effects: Permutes the elements in the range [first, last) such that each possible permutation of those elements has equal probability of appearance.

3 Returns: last for the overloads in namespace ranges.

4 Complexity: Exactly $(last - first) - 1$ swaps.
Remarks: To the extent that the implementation of this function makes use of random numbers, the object referenced by \texttt{g} shall serve as the implementation’s source of randomness.

25.7.14 Shift

\begin{verbatim}
template<class ForwardIterator>
constexpr ForwardIterator
shift_left(ForwardIterator first, ForwardIterator last,
type::iterator_traits<ForwardIterator>::difference_type n);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
shift_left(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
type::iterator_traits<ForwardIterator>::difference_type n);
\end{verbatim}

Preconditions: \(n \geq 0\) is true. The type of *\texttt{first} meets the \texttt{Cpp17MoveAssign} requirements.

Effects: If \(n = 0\) or \(n \geq \text{last} - \text{first}\), does nothing. Otherwise, moves the element from position \(\text{first} + n + i\) into position \(\text{first} + i\) for each non-negative integer \(i < (\text{last} - \text{first}) - n\). In the first overload case, does so in order starting from \(i = 0\) and proceeding to \(i = (\text{last} - \text{first}) - n - 1\).

Returns: \(\text{first} + (\text{last} - \text{first} - n)\) if \(n < \text{last} - \text{first}\), otherwise \(\text{first}\).

Complexity: At most \((\text{last} - \text{first}) - n\) assignments.

\begin{verbatim}
template<class ForwardIterator>
constexpr ForwardIterator
shift_right(ForwardIterator first, ForwardIterator last,
type::iterator_traits<ForwardIterator>::difference_type n);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
shift_right(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
type::iterator_traits<ForwardIterator>::difference_type n);
\end{verbatim}

Preconditions: \(n \geq 0\) is true. The type of *\texttt{first} meets the \texttt{Cpp17MoveAssign} requirements. \texttt{ForwardIterator} meets the \texttt{Cpp17BidirectionalIterator} requirements (23.3.5.5) or the \texttt{Cpp17ValueSwappable} requirements.

Effects: If \(n = 0\) or \(n \geq \text{last} - \text{first}\), does nothing. Otherwise, moves the element from position \(\text{first} + i\) into position \(\text{first} + n + i\) for each non-negative integer \(i < (\text{last} - \text{first}) - n\). In the first overload case, if \texttt{ForwardIterator} meets the \texttt{Cpp17BidirectionalIterator} requirements, does so in order starting from \(i = (\text{last} - \text{first}) - n - 1\) and proceeding to \(i = 0\).

Returns: \(\text{first} + n\) if \(n < \text{last} - \text{first}\), otherwise \(\text{last}\).

Complexity: At most \((\text{last} - \text{first}) - n\) assignments or swaps.

25.8 Sorting and related operations

\begin{verbatim}
Compare
\end{verbatim}

Compare is a function object type (20.14) that meets the requirements for a template parameter named \texttt{BinaryPredicate} (25.2). The return value of the function call operation applied to an object of type \texttt{Compare}, when contextually converted to \texttt{bool} (7.3), yields \texttt{true} if the first argument of the call is less than the second, and \texttt{false} otherwise.

\texttt{Compare} \texttt{comp} is used throughout for algorithms assuming an ordering relation.

For all algorithms that take \texttt{Compare}, there is a version that uses \texttt{operator<} instead. That is, \texttt{comp(*i, *j) != false} defaults to \texttt{*i < *j != false}. For algorithms other than those described in 25.8.3, \texttt{comp} shall induce a strict weak ordering on the values.

The term \textit{strict} refers to the requirement of an irreflexive relation (\texttt{!comp(x, x)} for all \texttt{x}), and the term \textit{weak} to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define \texttt{equiv(a, b)} as \texttt{!comp(a, b) && !comp(b, a)}, then the requirements are that \texttt{comp} and \texttt{equiv} both be transitive relations:

\begin{verbatim}
- \texttt{comp(a, b) && comp(b, c)} implies \texttt{comp(a, c)}
- \texttt{equiv(a, b) && equiv(b, c)} implies \texttt{equiv(a, c)}
\end{verbatim}

\[\text{Note: Under these conditions, it can be shown that}\]

\begin{verbatim}
- \texttt{equiv} is an equivalence relation,
\end{verbatim}
— comp induces a well-defined relation on the equivalence classes determined by \texttt{equiv}, and

— the induced relation is a strict total ordering.

\[\text{end note}\]

5 A sequence is \textit{sorted with respect to a comp and proj} for a comparator and projection comp and proj if for every iterator \(i\) pointing to the sequence and every non-negative integer \(n\) such that \(i + n\) is a valid iterator pointing to an element of the sequence,

\[
\text{bool}(\text{invoke(comp, invoke(proj, *(i + n)), invoke(proj, *i)))}
\]

is \textit{false}.

6 A sequence \([\text{start}, \text{finish})\] is \textit{partitioned with respect to an expression} \(f(e)\) if there exists an integer \(n\) such that for all \(0 \leq i < (\text{finish} - \text{start}), f(*(\text{start} + i))\) is true if and only if \(i < n\).

7 In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an \texttt{operator==}, but an equivalence relation induced by the strict weak ordering. That is, two elements \(a\) and \(b\) are considered equivalent if and only if \(! (a < b) \&\& ! (b < a)\).

25.8.1 Sorting

25.8.1.1 \texttt{sort}

\begin{verbatim}
template<class RandomAccessIterator>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last,
                    Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last,
          Compare comp);
\end{verbatim}

\begin{verbatim}
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::sort(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::sort(R&& r, Comp comp = {}, Proj proj = {});
\end{verbatim}

1 Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

2 \textit{ Preconditions:} For the overloads in namespace std, \texttt{RandomAccessIterator} meets the Cpp17ValueSwappable requirements (16.5.3.2) and the type of \texttt{*first} meets the Cpp17MoveConstructible (Table 28) and Cpp17MoveAssignable (Table 30) requirements.

3 \textit{Effects:} Sorts the elements in the range [\texttt{first}, \texttt{last}) with respect to \texttt{comp} and \texttt{proj}.

4 \textit{Returns:} \texttt{last} for the overloads in namespace ranges.

5 \textit{Complexity:} Let \(N\) be \texttt{last} - \texttt{first}. \(O(N \log N)\) comparisons and projections.

25.8.1.2 \texttt{stable_sort}

\begin{verbatim}
template<class RandomAccessIterator>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void stable_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator last);
\end{verbatim}

\[\text{§ 25.8.1.2}\]
template<class RandomAccessIterator, class Compare>  
void stable_sort(RandomAccessIterator first, RandomAccessIterator last,  
Compare comp);  
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>  
void stable_sort(ExecutionPolicy&& exec,  
RandomAccessIterator first, RandomAccessIterator last,  
Compare comp);  

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,  
class Proj = identity>  
I ranges::stable_sort(I first, S last, Comp comp = {}, Proj proj = {});  
template<random_access_range R, class Comp = ranges::less, class Proj = identity>  
requires sortable<iterator_t<R>, Comp, Proj>  
borrowed_iterator_t<R>  
ranges::stable_sort(R&& r, Comp comp = {}, Proj proj = {});  

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace std, RandomAccessIterator meets the Cpp17ValueSwappable requirements (16.5.3.2) and the type of *first meets the Cpp17MoveConstructible (Table 28) and Cpp17MoveAssignable (Table 30) requirements.

Effects: Sorts the elements in the range [first, last) with respect to comp and proj.

Returns: last for the overloads in namespace ranges.

Complexity: Let N be last - first. If enough extra memory is available, N \log(N) comparisons. Otherwise, at most N \log_2(N) comparisons. In either case, twice as many projections as the number of comparisons.

Remarks: Stable (16.5.5.8).

25.8.1.3 partial_sort

template<class RandomAccessIterator>  
constexpr void partial_sort(RandomAccessIterator first,  
RandomAccessIterator middle,  
RandomAccessIterator last);  
template<class ExecutionPolicy, class RandomAccessIterator>  
void partial_sort(ExecutionPolicy&& exec,  
RandomAccessIterator first,  
RandomAccessIterator middle,  
RandomAccessIterator last);  

template<class RandomAccessIterator, class Compare>  
constexpr void partial_sort(RandomAccessIterator first,  
RandomAccessIterator middle,  
RandomAccessIterator last,  
Compare comp);  
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>  
void partial_sort(ExecutionPolicy&& exec,  
RandomAccessIterator first,  
RandomAccessIterator middle,  
RandomAccessIterator last,  
Compare comp);  

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,  
class Proj = identity>  
requires sortable<I, Comp, Proj>  
I ranges::partial_sort(I first, I middle, S last, Comp comp = {}, Proj proj = {});  

template<random_access_range R, class Comp = ranges::less, class Proj = identity>  
requires sortable<iterator_t<R>, Comp, Proj>  
borrowed_iterator_t<R>  
ranges::partial_sort(R&& r, Comp comp = {}, Proj proj = {});  

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Preconditions: [first, middle) and [middle, last) are valid ranges. For the overloads in namespace std, RandomAccessIterator meets the Cpp17ValueSwappable requirements (16.5.3.2) and the type of *first meets the Cpp17MoveConstructible (Table 28) and Cpp17MoveAssignable (Table 30) requirements.
Effects: Places the first \texttt{middle - first} elements from the range \texttt{[first, last)} as sorted with respect to \texttt{comp} and \texttt{proj} into the range \texttt{[first, middle)} The rest of the elements in the range \texttt{[middle, last)} are placed in an unspecified order.

Returns: \texttt{last} for the overload in namespace \texttt{ranges}.

Complexity: Approximately \((last - first) \ast \log(middle - first)\) comparisons, and twice as many projections.

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
 requires sortable<iterator_t<R>, Comp, Proj>
 constexpr borrowed_iterator_t<R>
ranges::partial_sort(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});

Effects: Equivalent to:
\[
\text{return ranges::partial_sort(ranges::begin(r), middle, ranges::end(r), comp, proj)};
\]

25.8.1.4 partial_sort_copy

(template<input_iterator I1, sentinel_for<I1> S1, random_access_iterator I2, sentinel_for<I2> S2, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
 requires indirectly_copyable<I1, I2> \&\& sortable<I2, Comp, Proj2> \&\& indirect_strict_weak_order<Comp, projected<I1, Proj1>, projected<I2, Proj2>>
 constexpr ranges::partial_sort_copy_result<I1, I2>
ranges::partial_sort_copy(I1 first, S1 last, I2 result_first, S2 result_last, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

(template<input_range R1, random_access_range R2, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
 requires indirectly_copyable<iterator_t<R1>, iterator_t<R2>> \&\& sortable<iterator_t<R2>, Comp, Proj2> \&\& indirect_strict_weak_order<Comp, projected<iterator_t<R1>, Proj1>, projected<iterator_t<R2>, Proj2>>
 constexpr ranges::partial_sort_copy_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::partial_sort_copy(R1&& r, R2&& result_r, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

Let \(N\) be \(\min(last - first, result_last - result_first)\). Let \texttt{comp} be \texttt{less{}}, and \texttt{proj1} and \texttt{proj2} be \texttt{identity{}} for the overloads with no parameters by those names.
Mandates: For the overloads in namespace `std`, the expression `*first` is writable (23.3.1) to `result_first`.

Preconditions: For the overloads in namespace `std`, `RandomAccessIterator` meets the `Cpp17ValueSwappable` requirements (16.5.3.2), the type of `*result_first` meets the `Cpp17MoveConstructible` (Table 28) and `Cpp17MoveAssignable` (Table 30) requirements.

For iterators `a1` and `b1` in `[first, last)`, and iterators `x2` and `y2` in `[result_first, result_last)`, after evaluating the assignment `*y2 = *b1`, let `E` be the value of

\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj1}, *a1), \text{invoke}(\text{proj2}, *y2))).
\]

Then, after evaluating the assignment `*x2 = *a1`, `E` is equal to

\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj2}, *x2), \text{invoke}(\text{proj2}, *y2))).
\]

[Note: Writing a value from the input range into the output range does not affect how it is ordered by `comp` and `proj1` or `proj2`. — end note]

Effects: Places the first `N` elements as sorted with respect to `comp` and `proj2` into the range `[result_first, result_first + N)`.

Returns:

1. `result_first + N` for the overloads in namespace `std`.
2. `{last, result_first + N}` for the overloads in namespace `ranges`.

Complexity: Approximately `(last - first) * \log N` comparisons, and twice as many projections.

25.8.1.5 `is_sorted` [is.sorted]

template<class ForwardIterator>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last);

Effects: Equivalent to: `return is_sorted_until(first, last) == last;`

template<class ExecutionPolicy, class ForwardIterator>
bool is_sorted(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:

\[
\text{return } \text{is_sorted_until}(\text{std::forward<ExecutionPolicy>(exec)}, \text{first}, \text{last}) == \text{last};
\]

template<class ForwardIterator, class Compare>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last,
Compare comp);

Effects: Equivalent to: `return is_sorted_until(first, last, comp) == last;`

template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Compare comp);

Effects: Equivalent to:

\[
\text{return } \text{is_sorted_until}(\text{std::forward<ExecutionPolicy>(exec)}, \text{first}, \text{last}, \text{comp}) == \text{last};
\]

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::is_sorted(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::is_sorted(R&& r, Comp comp = {}, Proj proj = {});

Effects: Equivalent to: `return ranges::is_sorted_until(first, last, comp, proj) == last;`

template<class ForwardIterator>
constexpr ForwardIterator
is_sorted_until(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
is_sorted_until(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);
template<class ForwardIterator, class Compare>
  constexpr ForwardIterator
  is_sorted_until(ForwardIterator first, ForwardIterator last,
                  Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
  ForwardIterator
  is_sorted_until(ExecutionPolicy&& exec,
                  ForwardIterator first, ForwardIterator last,
                  Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
         indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
  constexpr I
  ranges::is_sorted_until(I first, S last, Comp comp = {}, Proj proj = {});

template<class RandomAccessIterator, class Compare>
  constexpr void
  nth_element(RandomAccessIterator first, RandomAccessIterator nth,
              RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
  void nth_element(ExecutionPolicy&& exec,
                   RandomAccessIterator first, RandomAccessIterator nth,
                   RandomAccessIterator last);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
  requires sortable<I, Comp, Proj>
  constexpr I
  ranges::nth_element(I first, I nth, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::nth_element(R&& r, iterator_t<R> nth, Comp comp = {}, Proj proj = {});

Effects: Equivalent to:
return ranges::nth_element(ranges::begin(r), nth, ranges::end(r), comp, proj);

25.8.3 Binary search
[alg.binary.search]

All of the algorithms in this subclause are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

25.8.3.1 lower_bound [lower.bound]

template<class ForwardIterator, class T>
constexpr ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last,
const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last,
const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::lower_bound(I first, S last, const T& value, Comp comp = {},
Proj proj = {});

template<forward_range R, class T, class Proj = identity,
indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::lower_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

Preconditions: The elements e of [first, last) are partitioned with respect to the expression bool(invoke(comp,
invoke(proj, e), value)).

Returns: The furthermost iterator i in the range [first, last] such that for every iterator j in the range [first, i),
bool(invoke(comp, invoke(proj, *j), value)) is true.

Complexity: At most \(\log_2(last - first) + O(1)\) comparisons and projections.

25.8.3.2 upper_bound [upper.bound]

template<class ForwardIterator, class T>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last,
const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last,
const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::upper_bound(I first, S last, const T& value, Comp comp = {},
Proj proj = {});
template<forward_range R, class T, class Proj = identity, 
indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = 
ranges::less>
constexpr borrowed_iterator_t<R>
ranges::upper_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});

Let comp be \textless\{} and proj be identity\{} for overloads with no parameters by those names.

Preconditions: The elements \( e \) of \([\text{first}, \text{last})\) are partitioned with respect to the expression \( \neg\text{bool}(\text{invoke}(\text{comp}, \text{value, invoke}(\text{proj}, e))) \).

Returns: The furthermost iterator \( i \) in the range \([\text{first}, \text{last})\) such that for every iterator \( j \) in the range \([\text{first}, i)\), \( \neg\text{bool}(\text{comp}(\text{value, invoke}(\text{proj}, *j))) \) is true.

Complexity: At most \( \log_2(\text{last} - \text{first}) + \mathcal{O}(1) \) comparisons and projections.

25.8.3.3 equal_range

template<class ForwardIterator, class T>
constexpr pair<ForwardIterator, ForwardIterator>
equal_range(ForwardIterator first, 
ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
equal_range(ForwardIterator first, 
ForwardIterator last, const T& value, 
Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity, 
indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr subrange<I>
equal_range(I first, S last, const T& value, Comp comp = {}, Proj proj = {});

Let comp be \textless\{} and proj be identity\{} for overloads with no parameters by those names.

Preconditions: The elements \( e \) of \([\text{first}, \text{last})\) are partitioned with respect to the expressions \( \neg\text{bool}(\text{invoke}(\text{comp, invoke}(\text{proj, e}), \text{value})) \) and \( \neg\text{bool}(\text{invoke}(\text{comp, value, invoke}(\text{proj, e}))) \). Also, for all elements \( e \) of \([\text{first}, \text{last})\), \( \neg\text{bool}(\text{comp}(\text{e, value})) \) implies \( \neg\text{bool}(\text{comp}(\text{value, e})) \) for the overloads in namespace std.

Returns:

(1) For the overloads in namespace std:

\{lower_bound(first, last, value, comp), 
upper_bound(first, last, value, comp)\}

(2) For the overloads in namespace ranges:

\{ranges::lower_bound(first, last, value, comp), 
ranges::upper_bound(first, last, value, comp)\}

Complexity: At most \( 2 \ast \log_2(\text{last} - \text{first}) + \mathcal{O}(1) \) comparisons and projections.

25.8.3.4 binary_search

template<class ForwardIterator, class T>
constexpr bool
binary_search(ForwardIterator first, ForwardIterator last, 
const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr bool
binary_search(ForwardIterator first, ForwardIterator last, 
const T& value, Compare comp);
template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
    indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::binary_search(I first, S last, const T& value, Comp comp = {},
    Proj proj = {});

template<forward_range R, class T, class Proj = identity,
    indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp =
    ranges::less>
constexpr bool ranges::binary_search(R&& r, const T& value, Comp comp = {},
    Proj proj = {});

Let \( \text{comp} \) be \( \text{less}{} \) and \( \text{proj} \) be \( \text{identity}{} \) for overloads with no parameters by those names.

Preconditions: The elements \( e \) of \([\text{first}, \text{last})\) are partitioned with respect to the expressions \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, e), \text{value})) \) and \( \text{!bool}(\text{invoke}(\text{comp}, \text{value}, \text{invoke}(\text{proj}, e))) \). Also, for all elements \( e \) of \([\text{first}, \text{last})\), \( \text{bool}(\text{comp}(e, \text{value})) \) implies \( \text{!bool}(\text{comp}(\text{value}, e)) \) for the overloads in namespace std.

Returns: true if and only if for some iterator \( i \) in the range \([\text{first}, \text{last})\), \( \text{!bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, *i), \text{value})) \) \&\& \( \text{!bool}(\text{invoke}(\text{comp}, \text{value}, \text{invoke}(\text{proj}, *i))) \) is true.

Complexity: At most \( \log_2(\text{last} - \text{first}) + O(1) \) comparisons and projections.

25.8.4 Partitions

Let \( \text{proj} \) be \( \text{identity}{} \) for the overloads with no parameter named \( \text{proj} \).

Returns: true if and only if the elements \( e \) of \([\text{first}, \text{last})\) are partitioned with respect to the expression \( \text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, e))) \).

Complexity: Linear. At most \( \text{last} - \text{first} \) applications of \( \text{pred} \) and \( \text{proj} \).

§ 25.8.4
Returns: Let \( i \) be an iterator such that \( E(*j) \) is true for every iterator \( j \) in \([\text{first}, i)\) and false for every iterator \( j \) in \([i, \text{last})\). Returns:

- \( i \) for the overloads in namespace std.
- \( \{i, \text{last}\} \) for the overloads in namespace ranges.

Complexity: Let \( N = \text{last} - \text{first} \):

- For the overload with no `ExecutionPolicy`, exactly \( N \) applications of the predicate and projection. At most \( N/2 \) swaps if the type of \( \text{first} \) meets the `Cpp17BidirectionalIterator` requirements for the overloads in namespace std or models `bidirectional_iterator` for the overloads in namespace ranges, and at most \( N \) swaps otherwise.

- For the overload with an `ExecutionPolicy`, \( \mathcal{O}(N \log N) \) swaps and \( \mathcal{O}(N) \) applications of the predicate.

```cpp
template<class BidirectionalIterator, class Predicate>
BidirectionalIterator
stable_partition(BidirectionalIterator first, BidirectionalIterator last, Predicate pred);

template<class ExecutionPolicy, class BidirectionalIterator, class Predicate>
BidirectionalIterator
stable_partition(ExecutionPolicy&& exec,
               BidirectionalIterator first, BidirectionalIterator last, Predicate pred);
```

Let \( \text{proj} \) be `identity` for the overloads with no parameter named `proj` and let \( E(x) \) be \( \text{bool}(\text{invoke}(\text{proj, invoke(pred, x})))).

Preconditions: For the overloads in namespace std, `BidirectionalIterator` meets the `Cpp17ValueSwappable` requirements (16.5.3.2) and the type of \( \ast \text{first} \) meets the `Cpp17MoveConstructible` (Table 28) and `Cpp17MoveAssignable` (Table 30) requirements.

Effects: Places all the elements \( e \) in \([\text{first}, \text{last})\) that satisfy \( E(e) \) before all the elements that do not. The relative order of the elements in both groups is preserved.

Returns: Let \( i \) be an iterator such that for every iterator \( j \) in \([\text{first}, i)\), \( E(*j) \) is true, and for every iterator \( j \) in the range \([i, \text{last})\), \( E(*j) \) is false. Returns:

- \( i \) for the overloads in namespace std.
- \( \{i, \text{last}\} \) for the overloads in namespace ranges.

Complexity: Let \( N = \text{last} - \text{first} \):

- For the overloads with no `ExecutionPolicy`, at most \( N \log N \) swaps, but only \( \mathcal{O}(N) \) swaps if there is enough extra memory. Exactly \( N \) applications of the predicate and projection.

- For the overload with an `ExecutionPolicy`, \( \mathcal{O}(N \log N) \) swaps and \( \mathcal{O}(N) \) applications of the predicate.

```cpp
§ 25.8.4
```
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O1, weakly_incrementable O2,
class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O1> & indirect_copyable<I, O2>
constexpr ranges::partition_copy(I first, S last, O1 out_true, O2 out_false, Pred pred,
  Proj proj = {});
template<input_range R, weakly_incrementable O1, weakly_incrementable O2,
class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O1> & indirectly_copyable<iterator_t<R>, O2>
constexpr ranges::partition_copy(borrowed_iterator_t<R>, O1 out_true, O2 out_false, Pred pred, Proj proj = {});

Let proj be identity{} for the overloads with no parameter named proj and let E(x) be bool:invoke(pred, invoke(proj, x)).

Mandates: For the overloads in namespace std, the expression *first is writable (23.3.1) to out_true and out_false.

Preconditions: The input range and output ranges do not overlap.
[Note: For the overload with an ExecutionPolicy, there may be a performance cost if first’s value type
does not meet the Cpp17CopyConstructible requirements. — end note]

Effects: For each iterator i in [first, last), copies *i to the output range beginning with out_true if E(*i) is true, or to the output range beginning with out_false otherwise.

Returns: Let o1 be the end of the output range beginning at out_true, and o2 the end of the output range beginning at out_false. Returns
  — {o1, o2} for the overloads in namespace std.
  — {last, o1, o2} for the overloads in namespace ranges.

Complexity: Exactly last - first applications of pred and proj.

template<class ForwardIterator, class Predicate>
constexpr ForwardIterator
partition_point(ForwardIterator first, ForwardIterator last, Predicate pred);

Let proj be identity{} for the overloads with no parameter named proj and let E(x) be bool:invoke(pred, invoke(proj, x)).

Preconditions: The elements e of [first, last) are partitioned with respect to E(e).

Returns: An iterator mid such that E(*i) is true for all iterators i in [first, mid), and false for all
  iterators i in [mid, last).

Complexity: O(log(last - first)) applications of pred and proj.

25.8.5 Merge [alg.merge]

template<class InputIterator1, class InputIterator2,
class OutputIterator>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1,
  InputIterator2 first2, InputIterator2 last2,
  OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
ForwardIterator
merge(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, InputIterator2 last2,
    OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator, class Compare>
ForwardIterator
merge(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
    weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity,
    class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
ranges::merge_result<I1, I2, O>
ranges::merge(I1 first1, S1 last1, I2 first2, S2 last2, O result,
    Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O, class Comp = ranges::less,
    class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
ranges::merge_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::merge(R1&& r1, R2&& r2, O result,
    Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

Let \( N \) be \((last1 - first1) + (last2 - first2)\). Let \( \text{comp be } \text{less}\{\}, \text{proj1 be } \text{identity}\{\}, \text{and proj2 be identity}\{\}\), for the overloads with no parameters by those names.

Preconditions: The ranges \([first1, last1)\) and \([first2, last2)\) are sorted with respect to \(\text{comp}\) and \(\text{proj1}\) or \(\text{proj2}\), respectively. The resulting range does not overlap with either of the original ranges.

Effects: Copies all the elements of the two ranges \([first1, last1)\) and \([first2, last2)\) into the range \([result, result_last)\), where \(result\_last\) is result + \(N\). If an element \(a\) precedes \(b\) in an input range, \(a\) is copied into the output range before \(b\). If \(e1\) is an element of \([first1, last1)\) and \(e2\) of \([first2, last2)\), \(e2\) is copied into the output range before \(e1\) if and only if bool(invoke(comp, invoke(proj2, e2), invoke(proj1, e1))) is true.

Returns:

(4.1) \(\text{result\_last for the overloads in namespace } \text{std}\).

(4.2) \(\{last1, last2, result\_last\} for the overloads in namespace ranges\).

Complexity:

(5.1) \(\text{For the overloads with no ExecutionPolicy, at most } N - 1 \text{ comparisons and applications of each projection.}\)

(5.2) \(\text{For the overloads with an ExecutionPolicy, } \mathcal{O}(N) \text{ comparisons.}\)

Remarks: Stable (16.5.5.8).

template<class BidirectionalIterator>
void inplace_merge(BidirectionalIterator first,
    BidirectionalIterator middle,
    BidirectionalIterator last);
template<class ExecutionPolicy, class BidirectionalIterator>
void inplace_merge(ExecutionPolicy&& exec,
    BidirectionalIterator first,
    BidirectionalIterator middle,
    BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
void inplace_merge(BidirectionalIterator first,
    BidirectionalIterator middle,
    BidirectionalIterator last, Compare comp);

template<class ExecutionPolicy, class BidirectionalIterator, class Compare>
void inplace_merge(ExecutionPolicy&& exec,
    BidirectionalIterator first,
    BidirectionalIterator middle,
    BidirectionalIterator last, Compare comp);

template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
    class Proj = identity>
requires sortable<I, Comp, Proj>
I ranges::inplace_merge(I first, I middle, S last, Comp comp = {}, Proj proj = {});

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

**Preconditions:** `[first, middle)` and `[middle, last)` are valid ranges sorted with respect to `comp` and `proj`. For the overloads in namespace `std`, `BidirectionalIterator` meets the `Cpp17ValueSwappable` requirements (16.5.3.2) and the type of `*first` meets the `Cpp17MoveConstructible` (Table 28) and `Cpp17MoveAssignable` (Table 30) requirements.

**Effects:** Merges two sorted consecutive ranges `[first, middle)` and `[middle, last)`, putting the result of the merge into the range `[first, last)`. The resulting range is sorted with respect to `comp` and `proj`.

**Returns:** `last` for the overload in namespace `ranges`.

**Complexity:** Let \( N = \text{last} - \text{first} \):

- For the overloads with no `ExecutionPolicy`, and if enough additional memory is available, exactly \( N - 1 \) comparisons.
- Otherwise, \( \Theta(N \log N) \) comparisons.

In either case, twice as many projections as comparisons.

**Remarks:** Stable (16.5.5.8).

template<bidirectional_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
borrowed_iterator_t<R>
ranges::inplace_merge(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});

**Effects:** Equivalent to:

\[
\text{return ranges::inplace_merge(ranges::begin(r), middle, ranges::end(r), comp, proj);}
\]

### 25.8.6 Set operations on sorted structures

This subclause defines all the basic set operations on sorted structures. They also work with multisets (22.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to multisets in a standard way by defining `set_union` to contain the maximum number of occurrences of every element, `set_intersection` to contain the minimum, and so on.

#### 25.8.6.1 includes

```cpp
template<class InputIterator1, class InputIterator2>
constexpr bool includes(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool includes(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2);
```
template<class InputIterator1, class InputIterator2, class Compare>
constexpr bool includes(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
bool includes(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
class Proj1 = identity, class Proj2 = identity,
indirect_strict_weak_order<projected<I1, Proj1>,
projected<I2, Proj2>> Comp = ranges::less>
constexpr bool ranges::includes(I1 first1, S1 last1, I2 first2, S2 last2, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, class Proj1 = identity,
class Proj2 = identity,
indirect_strict_weak_order<iterator_t<R1>, Proj1>,
iterator_t<R2>, Proj2>> Comp = ranges::less>
constexpr bool ranges::includes(R1&& r1, R2&& r2, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

Let comp be less{}, proj1 be identity{}, and proj2 be identity{}, for the overloads with no parameters
by those names.

Preconditions: The ranges [first1, last1) and [first2, last2) are sorted with respect to comp and proj1 or proj2, respectively.

Returns: true if and only if [first2, last2) is a subsequence of [first1, last1). [Note: A sequence S
is a subsequence of another sequence T if S can be obtained from T by removing some, all, or none of T’s
elements and keeping the remaining elements in the same order. — end note]

Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons and applications
of each projection.

25.8.6.2 set_union

template<class InputIterator1, class InputIterator2,
class OutputIterator>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator,
class OutputIterator>
ForwardIterator
set_union(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result);

§ 25.8.6.2 1083
Let \( \text{comp} \) be \( \text{less\{} \), and \( \text{proj1} \) and \( \text{proj2} \) be \( \text{id}\{\}\) for the overloads with no parameters by those names.

**Preconditions:** The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) are sorted with respect to \( \text{comp} \) and \( \text{proj1} \) or \( \text{proj2} \), respectively. The resulting range does not overlap with either of the original ranges.

**Effects:** Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

**Returns:** Let \( \text{result\_last} \) be the end of the constructed range. Returns

1. \( \text{result\_last} \) for the overloads in namespace std.
2. \{last1, last2, result\_last\} for the overloads in namespace ranges.

**Complexity:** At most \( 2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1 \) comparisons and applications of each projection.

**Remarks:** Stable (16.5.5.8). If \([\text{first1}, \text{last1})\) contains \( m \) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \( n \) elements that are equivalent to them, then all \( m \) elements from the first range are copied to the output range, in order, and then the final \( \max(n - m, 0) \) elements from the second range are copied to the output range, in order.
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
weakly_incrementable O, class Comp = ranges::less,
class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<I1, I2, O>
ranges::set_intersection(I1 first1, S1 last1, I2 first2, S2 last2, O result,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, weakly_incrementable O,
class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::set_intersection(R1&& r1, R2&& r2, O result,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let comp be less{}, and proj1 and proj2 be identity{} for the overloads with no parameters by those names.

2 Preconditions: The ranges [first1, last1) and [first2, last2) are sorted with respect to comp and proj1 or proj2, respectively. The resulting range does not overlap with either of the original ranges.

3 Effects: Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements that are present in both of the ranges.

4 Returns: Let result_last be the end of the constructed range. Returns
   
   — result_last for the overloads in namespace std.
   
   — {last1, last2, result_last} for the overloads in namespace ranges.

5 Complexity: At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons and applications of each projection.

6 Remarks: Stable (16.5.5.8). If [first1, last1) contains \(m\) elements that are equivalent to each other and [first2, last2) contains \(n\) elements that are equivalent to them, the first \(\min(m, n)\) elements are copied from the first range to the output range, in order.

25.8.6.4 set_difference

template<class InputIterator1, class InputIterator2,
class OutputIterator>
constexpr OutputIterator
set_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator>
ForwardIterator
set_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result);

template<class InputIterator1, class InputIterator2,
class OutputIterator, class Compare>
constexpr OutputIterator
set_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result, Compare comp);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator, class Compare>
ForwardIterator
set_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result, Compare comp);
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
weakly_incrementable O, class Comp = ranges::less,
class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<I1, O>
ranges::set_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O,
class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<borrowed_iterator_t<R1>, O>
ranges::set_difference(R1&& r1, R2&& r2, O result,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let comp be less{}, and proj1 and proj2 be identity{} for the overloads with no parameters by those names.

2 Preconditions: The ranges [first1, last1) and [first2, last2) are sorted with respect to comp and proj1 or proj2, respectively. The resulting range does not overlap with either of the original ranges.

3 Effects: Copies the elements of the range [first1, last1) which are not present in the range [first2, last2) to the range beginning at result. The elements in the constructed range are sorted.

4 Returns: Let result_last be the end of the constructed range. Returns
   - result_last for the overloads in namespace std.
   - {last1, result_last} for the overloads in namespace ranges.

5 Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons and applications of each projection.

6 Remarks: If [first1, last1) contains m elements that are equivalent to each other and [first2, last2) contains n elements that are equivalent to them, the last max(m − n, 0) elements from [first1, last1) is copied to the output range, in order.

25.8.6.5 set_symmetric_difference

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator, class Compare>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result, Compare comp);
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<I1, I2, O>
ranges::set_symmetric_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::set_symmetric_difference(R1&& r1, R2&& r2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let comp be less{}, and proj1 and proj2 be identity{} for the overloads with no parameters by those names.

2 Preconditions: The ranges [first1, last1) and [first2, last2) are sorted with respect to comp and proj1 or proj2, respectively. The resulting range does not overlap with either of the original ranges.

3 Effects: Copies the elements of the range [first1, last1) that are not present in the range [first2, last2), and the elements of the range [first2, last2) that are not present in the range [first1, last1) to the range beginning at result. The elements in the constructed range are sorted.

4 Returns: Let result_last be the end of the constructed range. Returns

(4.1) result_last for the overloads in namespace std.

(4.2) {last1, last2, result_last} for the overloads in namespace ranges.

5 Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons and applications of each projection.

6 Remarks: Stable (16.5.5.8). If [first1, last1) contains m elements that are equivalent to each other and [first2, last2) contains n elements that are equivalent to them, then |m - n| of those elements shall be copied to the output range: the last m - n of these elements from [first1, last1) if m > n, and the last n - m of these elements from [first2, last2) if m < n. In either case, the elements are copied in order.

25.8.7 Heap operations [alg.heap.operations]

1 A random access range [a, b) is a heap with respect to comp and proj for a comparator and projection comp and proj if its elements are organized such that:

(1.1) With \( N = b - a \), for all \( i, 0 < i < N \), \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, a[\lfloor i/2 \rfloor])), \text{invoke}(\text{proj}, a[i])) \) is false.

(1.2) \(*a\) may be removed by pop_heap, or a new element added by push_heap, in \( O(\log N) \) time.

2 These properties make heaps useful as priority queues.

3 make_heap converts a range into a heap and sort_heap turns a heap into a sorted sequence.

25.8.7.1 push_heap [push.heap]

template<class RandomAccessIterator>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less, class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::push_heap(I first, S last, Comp comp = {}, Proj proj = {});
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::push_heap(R&& r, Comp comp = {}, Proj proj = {});

Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

**Preconditions:** The range \([\texttt{first}, \texttt{last} - 1)\) is a valid heap with respect to \texttt{comp} and \texttt{proj}. For the overloads in namespace \texttt{std}, the type of \*\texttt{first} meets the \texttt{Cpp17MoveConstructible} requirements (Table 28) and the \texttt{Cpp17MoveAssignable} requirements (Table 30).

**Effects:** Places the value in the location \(\texttt{last} - 1\) into the resulting heap \([\texttt{first}, \texttt{last})\).

**Returns:** \texttt{last} for the overloads in namespace \texttt{ranges}.

**Complexity:** At most \(\log(\texttt{last} - \texttt{first})\) comparisons and twice as many projections.

### 25.8.7.2 pop_heap

```cpp
template<class RandomAccessIterator>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

**Preconditions:** The range \([\texttt{first}, \texttt{last})\) is a valid non-empty heap with respect to \texttt{comp} and \texttt{proj}. For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} meets the \texttt{Cpp17ValueSwappable} requirements (16.5.3.2) and the type of \*\texttt{first} meets the \texttt{Cpp17MoveConstructible} (Table 28) and \texttt{Cpp17MoveAssignable} (Table 30) requirements.

**Effects:** Swaps the value in the location \texttt{first} with the value in the location \(\texttt{last} - 1\) and makes \([\texttt{first}, \texttt{last} - 1)\) into a heap with respect to \texttt{comp} and \texttt{proj}.

**Returns:** \texttt{last} for the overloads in namespace \texttt{ranges}.

**Complexity:** At most \(2 \log(\texttt{last} - \texttt{first})\) comparisons and twice as many projections.

### 25.8.7.3 make_heap

```cpp
template<class RandomAccessIterator>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

**Preconditions:** The range \([\texttt{first}, \texttt{last})\) is a valid non-empty heap with respect to \texttt{comp} and \texttt{proj}. For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} meets the \texttt{Cpp17ValueSwappable} requirements (16.5.3.2) and the type of \*\texttt{first} meets the \texttt{Cpp17MoveConstructible} (Table 28) and \texttt{Cpp17MoveAssignable} (Table 30) requirements.

**Effects:** Swaps the value in the location \texttt{first} with the value in the location \(\texttt{last} - 1\) and makes \([\texttt{first}, \texttt{last} - 1)\) into a heap with respect to \texttt{comp} and \texttt{proj}.

**Returns:** \texttt{last} for the overloads in namespace \texttt{ranges}.

**Complexity:** At most \(2 \log(\texttt{last} - \texttt{first})\) comparisons and twice as many projections.
2  **Preconditions:** For the overloads in namespace `std`, the type of `*first` meets the `Cpp17MoveConstructible` (Table 28) and `Cpp17MoveAssignable` (Table 30) requirements.

3  **Effects:** Constructs a heap with respect to `comp` and `proj` out of the range `[first, last)`.

4  **Returns:** `last` for the overloads in namespace `ranges`.

5  **Complexity:** At most 3(last - first) comparisons and twice as many projections.

25.8.7.4  `sort_heap`

```cpp
template<class RandomAccessIterator>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

```cpp
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less, class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::sort_heap(I first, S last, Comp comp = {}, Proj proj = {});
```

```cpp
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::sort_heap(R&& r, Comp comp = {}, Proj proj = {});
```

1  Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

2  **Preconditions:** The range `[first, last)` is a valid heap with respect to `comp` and `proj`. For the overloads in namespace `std`, `RandomAccessIterator` meets the `Cpp17ValueSwappable` requirements (16.5.3.2) and the type of `*first` meets the `Cpp17MoveConstructible` (Table 28) and `Cpp17MoveAssignable` (Table 30) requirements.

3  **Effects:** Sorts elements in the heap `[first, last)` with respect to `comp` and `proj`.

4  **Returns:** `last` for the overloads in namespace `ranges`.

5  **Complexity:** At most $2N \log N$ comparisons, where $N = last - first$, and twice as many projections.

25.8.7.5  `is_heap`

```cpp
template<class RandomAccessIterator>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class ExecutionPolicy, class RandomAccessIterator>
bool is_heap(ExecutionPolicy&& exec, RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

```cpp
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
bool is_heap(ExecutionPolicy&& exec, RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

1  **Effects:** Equivalent to: `return is_heap_until(first, last) == last;`

2  **Effects:** Equivalent to:

   ```cpp
   return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last) == last;
   ```

3  **Effects:** Equivalent to: `return is_heap_until(first, last, comp) == last;`

4  **Effects:** Equivalent to:

   ```cpp
   return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;
   ```

```cpp
template<random_access_iterator I, sentinel_for<I> S, class Proj = identity, indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::is_heap(I first, S last, Comp comp = {}, Proj proj = {});
```
template<random_access_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr I ranges::is_heap_until(I first, S last, Comp comp = {}, Proj proj = {});

Effects:

Equivalent to: return ranges::is_heap_until(first, last, comp, proj) == last;

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Returns: The last iterator i in [first, last] for which the range [first, i) is a heap with respect to comp
and proj.

Complexity: Linear.

### 25.8.8 Minimum and maximum

[alg.min.max]

template<class T>
constexpr const T& min(const T& a, const T& b);

template<class T, class Compare>
constexpr const T& min(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity,
    indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T& ranges::min(const T& a, const T& b, Comp comp = {}, Proj proj = {});

Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 26).

Returns: The smaller value. Returns the first argument when the arguments are equivalent.

Complexity: Exactly one comparison and two applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in
namespace std.

template<class T>
constexpr T min(initializer_list<T> r);

template<class T, class Compare>
constexpr T min(initializer_list<T> r, Compare comp);

template<copyable T, class Proj = identity,
    indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr T ranges::min(initializer_list<T> r, Comp comp = {}, Proj proj = {});
template<input_range R, class Proj = identity, indirect_strict_weak_order<projected<iterator_t<R>>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>>
constexpr range_value_t<R>
ranges::min(R&& r, Comp comp = {}, Proj proj = {});

5 Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17CopyConstructible requirements. For the first form, T meets the Cpp17LessThanComparable requirements (Table 26).

6 Returns: The smallest value in the input range. Returns a copy of the leftmost element when several elements are equivalent to the smallest.

7 Complexity: Exactly ranges::distance(r) - 1 comparisons and twice as many applications of the projection, if any.

8 Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

template<class T>
constexpr const T& max(const T& a, const T& b);
template<class T, class Compare>
constexpr const T& max(const T& a, const T& b, Compare comp);

9 template<class T, class Proj = identity, indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T& ranges::max(const T& a, const T& b, Comp comp = {}, Proj proj = {});

10 Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 26).

11 Returns: The larger value. Returns the first argument when the arguments are equivalent.

12 Complexity: Exactly one comparison and two applications of the projection, if any.

13 Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

template<class T>
constexpr T max(initializer_list<T> r);
template<class T, class Compare>
constexpr T max(initializer_list<T> r, Compare comp);

14 template<copyable T, class Proj = identity, indirect_strict_weak_order<projected<initializer_list<T>, Proj>> Comp = ranges::less>
constexpr T ranges::max(initializer_list<T> r, Comp comp = {}, Proj proj = {});

15 template<input_range R, class Proj = identity, indirect_strict_weak_order<projected<iterator_t<R>>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>>
constexpr range_value_t<R>
ranges::max(R&& r, Comp comp = {}, Proj proj = {});

16 Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17CopyConstructible requirements. For the first form, T meets the Cpp17LessThanComparable requirements (Table 26).

17 Returns: The largest value in the input range. Returns a copy of the leftmost element when several elements are equivalent to the largest.

18 Complexity: Exactly ranges::distance(r) - 1 comparisons and twice as many applications of the projection, if any.

19 Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

template<class T>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b);
template<class T, class Compare>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b, Compare comp);
template<class T, class Proj = identity,
    indirect_strict_weak_order<Projected<const T*, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<const T&> ranges::minmax(const T& a, const T& b, Comp comp = {}, Proj proj = {});

17 Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 26).
18 Returns: \{b, a\} if b is smaller than a, and \{a, b\} otherwise.
19 Complexity: Exactly one comparison and two applications of the projection, if any.
20 Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

template<class T>
constexpr pair<T, T> minmax(initializer_list<T> t);
template<class T, class Compare>
constexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);

21 Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17CopyConstructible requirements. For the first form, type T meets the Cpp17LessThanComparable requirements (Table 26).
22 Returns: Let X be the return type. Returns X\{x, y\}, where x is a copy of the leftmost element with the smallest value and y a copy of the rightmost element with the largest value in the input range.
23 Complexity: At most \((3/2)\) ranges::distance(r) applications of the corresponding predicate and twice as many applications of the projection, if any.
24 Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

template<class ForwardIterator>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last);

25 Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.
26 Returns: The first iterator i in the range \([\text{first, last})\) such that for every iterator j in the range \([\text{first, last})\),
bool(invoke(comp, invoke(proj, *j), invoke(proj, *i)))
is false. Returns last if first == last.

**Complexity:** Exactly max(last - first - 1, 0) comparisons and twice as many projections.

```cpp
template<class ForwardIterator>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator max_element(ExecutionPolicy& exec,
ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ForwardIterator, class Compare>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last, Compare comp);
template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator max_element(ExecutionPolicy& exec,
ForwardIterator first, ForwardIterator last, Compare comp);
```

```cpp
template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::max_element(I first, S last, Comp comp = {}, Proj proj = {});
template<forward_range R, class Proj = identity,
indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Proj = ranges::less>
constexpr borrowed_iterator_t<R> ranges::max_element(R&& r, Comp comp = {}, Proj proj = {});
```

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

**Returns:** The first iterator i in the range [first, last) such that for every iterator j in the range [first, last),
bool(invoke(comp, invoke(proj, *i), invoke(proj, *j)))
is false. Returns last if first == last.

**Complexity:** Exactly max(last - first - 1, 0) comparisons and twice as many projections.

```cpp
template<class ForwardIterator>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
pair<ForwardIterator, ForwardIterator> minmax_element(ExecutionPolicy& exec,
ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ForwardIterator, class Compare>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);
template<class ExecutionPolicy, class ForwardIterator, class Compare>
pair<ForwardIterator, ForwardIterator> minmax_element(ExecutionPolicy& exec,
ForwardIterator first, ForwardIterator last, Compare comp);
```

```cpp
template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<I> ranges::minmax_element(I first, S last, Comp comp = {}, Proj proj = {});
template<forward_range R, class Proj = identity,
indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<borrowed_iterator_t<R>> ranges::minmax_element(R&& r, Comp comp = {}, Proj proj = {});
```

**Returns:** {first, first} if [first, last) is empty, otherwise {m, M}, where m is the first iterator in [first, last) such that no iterator in the range refers to a smaller element, and where M is the last iterator in [first, last) such that no iterator in the range refers to a larger element.

---

2734 This behavior intentionally differs from max_element.
32. Complexity: Let \(N\) be last - first. At most \(\max(\left\lfloor \frac{3}{2}(N - 1) \right\rfloor, 0)\) comparisons and twice as many applications of the projection, if any.

### 25.8.9 Bounded value

[alg.clamp]

```cpp
template<class T>
constexpr const T& clamp(const T& v, const T& lo, const T& hi);
template<class T, class Compare>
constexpr const T& clamp(const T& v, const T& lo, const T& hi, Compare comp);
template<class T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T&
ranges::clamp(const T& v, const T& lo, const T& hi, Comp comp = {}, Proj proj = {});
```

1. Let \(\text{comp}\) be \(\text{less}\{\}\) for the overloads with no parameter \(\text{comp}\), and let \(\text{proj}\) be \(\text{identity}\{\}\) for the overloads with no parameter \(\text{proj}\).

2. Preconditions: \(\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, \text{hi}), \text{invoke}(\text{proj}, \text{lo})))\) is false. For the first form, type \(T\) meets the \(\text{Cpp17LessThanComparable}\) requirements (Table 26).

3. Returns: \(\text{lo}\) if \(\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, \text{lo}), \text{v}))\) is true, \(\text{hi}\) if \(\text{bool}(\text{invoke}(\text{comp}, \text{proj}, \text{v}))\) is true, otherwise \(v\).

4. [Note: If NaN is avoided, \(T\) can be a floating-point type. — end note]

5. Complexity: At most two comparisons and three applications of the projection.

### 25.8.10 Lexicographical comparison

[alg.lex.comparison]

```cpp
template<class InputIterator1, class InputIterator2>
constexpr bool lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, InputIterator2 last2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool lexicographical_compare(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2);
```

```
```
```
```
```
Proj1 proj1 = {}, Proj2 proj2 = {};

Returns: true if and only if the sequence of elements defined by the range [first1, last1) is lexicographically less than the sequence of elements defined by the range [first2, last2).

Complexity: At most $2 \min(last1 - first1, last2 - first2)$ applications of the corresponding comparison and each projection, if any.

Remarks: If two sequences have the same number of elements and their corresponding elements (if any) are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a proper prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

Example: ranges::lexicographical_compare(I1, S1, I2, S2, Comp, Proj1, Proj2) could be implemented as:

```cpp
for ( ; first1 != last1 && first2 != last2 ; ++first1, (void) ++first2) {
    if (invoke(comp, invoke(proj1, *first1), invoke(proj2, *first2))) return true;
    if (invoke(comp, invoke(proj2, *first2), invoke(proj1, *first1))) return false;
}
return first1 == last1 && first2 != last2;
```

Note: An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence.

25.8.11 Three-way comparison algorithms

```cpp
template<class InputIterator1, class InputIterator2, class Cmp>
constexpr auto lexicographical_compare_three_way(InputIterator1 b1, InputIterator1 e1,
                                                InputIterator2 b2, InputIterator2 e2,
                                                Cmp comp)
-> decltype(comp(*b1, *b2));
```

- **Mandates:** decltype(comp(*b1, *b2)) is a comparison category type.
- **Effects:** Lexicographically compares two ranges and produces a result of the strongest applicable comparison category type. Equivalent to:

```cpp
for ( ; b1 != e1 && b2 != e2; void(++b1), void(++b2) )
    if (auto cmp = comp(*b1,*b2); cmp != 0)
        return cmp;
    return b1 != e1 ? strong_ordering::greater :
                    b2 != e2 ? strong_ordering::less :
                    strong_ordering::equal;
```

25.8.12 Permutation generators

```cpp
template<class BidirectionalIterator>
constexpr bool next_permutation(BidirectionalIterator first,
                                BidirectionalIterator last);
```

```cpp
template<class BidirectionalIterator, class Compare>
constexpr bool next_permutation(BidirectionalIterator first,
                                BidirectionalIterator last, Compare comp);
```
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
    class Proj = identity>
constexpr ranges::next_permutation_result<I>
    ranges::next_permutation(I first, S last, Comp comp = {}, Proj proj = {});

template<bidirectional_range R, class Comp = ranges::less,
    class Proj = identity>
constexpr ranges::next_permutation_result<borrowed_iterator_t<R>>
    ranges::next_permutation(R&& r, Comp comp = {}, Proj proj = {});

1. Let comp be `less{}` and proj be `identity{}` for overloads with no parameters by those names.

2. **Preconditions:** For the overloads in namespace `std`, `BidirectionalIterator` meets the `Cpp17ValueSwappable` requirements (16.5.3.2).

3. **Effects:** Takes a sequence defined by the range `[first, last)` and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to `comp` and `proj`. If no such permutation exists, transforms the sequence into the first permutation; that is, the ascendingly-sorted one.

4. **Returns:** Let B be true if a next permutation was found and otherwise false. Returns:

   - B for the overloads in namespace `std`.
   - `{ last, B }` for the overloads in namespace `ranges`.

5. **Complexity:** At most \((last - first) / 2\) swaps.

---

template<class BidirectionalIterator>
constexpr bool prev_permutation(BidirectionalIterator first,
    BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
constexpr bool prev_permutation(BidirectionalIterator first,
    BidirectionalIterator last, Compare comp);

template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
    class Proj = identity>
constexpr ranges::prev_permutation_result<I>
    ranges::prev_permutation(I first, S last, Comp comp = {}, Proj proj = {});

template<bidirectional_range R, class Comp = ranges::less,
    class Proj = identity>
constexpr ranges::prev_permutation_result<borrowed_iterator_t<R>>
    ranges::prev_permutation(R&& r, Comp comp = {}, Proj proj = {});

6. Let comp be `less{}` and proj be `identity{}` for overloads with no parameters by those names.

7. **Preconditions:** For the overloads in namespace `std`, `BidirectionalIterator` meets the `Cpp17ValueSwappable` requirements (16.5.3.2).

8. **Effects:** Takes a sequence defined by the range `[first, last)` and transforms it into the previous permutation. The previous permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to `comp` and `proj`. If no such permutation exists, transforms the sequence into the last permutation; that is, the descendingly-sorted one.

9. **Returns:** Let B be true if a previous permutation was found and otherwise false. Returns:

   - B for the overloads in namespace `std`.
   - `{ last, B }` for the overloads in namespace `ranges`.

10. **Complexity:** At most \((last - first) / 2\) swaps.

---

### 25.9 Header `<numeric>` synopsis

```cpp

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryOperation, class UnaryOperation>
ForwardIterator2
transform_inclusive_scan(ExecutionPolicy&& exec, // see 25.3.5
                         ForwardIterator1 first, ForwardIterator1 last,
                         ForwardIterator2 result, BinaryOperation binary_op,
                         UnaryOperation unary_op);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryOperation, class UnaryOperation, class T>
ForwardIterator2
transform_inclusive_scan(ExecutionPolicy&& exec, // see 25.3.5
                         ForwardIterator1 first, ForwardIterator1 last,
                         ForwardIterator2 result, BinaryOperation binary_op,
                         UnaryOperation unary_op, T init);
```

// 25.10.11, adjacent difference

```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator
adjacent_difference(InputIterator first, InputIterator last,
                     OutputIterator result);
```

```cpp
template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
adjacent_difference(InputIterator first, InputIterator last,
                     OutputIterator result, BinaryOperation binary_op);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec, // see 25.3.5
                    ForwardIterator1 first, ForwardIterator1 last,
                    ForwardIterator2 result);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryOperation>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec, // see 25.3.5
                    ForwardIterator1 first, ForwardIterator1 last,
                    ForwardIterator2 result, BinaryOperation binary_op);
```
// 25.10.12, iota
template<class ForwardIterator, class T>
constexpr void iota(ForwardIterator first, ForwardIterator last, T value);

// 25.10.13, greatest common divisor
template<class M, class N>
constexpr common_type_t<M,N> gcd(M m, N n);

// 25.10.14, least common multiple
template<class M, class N>
constexpr common_type_t<M,N> lcm(M m, N n);

// 25.10.15, midpoint
template<class T>
constexpr T midpoint(T a, T b) noexcept;
template<class T>
constexpr T* midpoint(T* a, T* b);

25.10 Generalized numeric operations [numeric.ops]
[Note: The use of closed ranges as well as semi-open ranges to specify requirements throughout this subclause is intentional. — end note]

25.10.1 Definitions [numerics.defns]
1 Define \texttt{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, a1, ..., aN) as follows:
\begin{align}
\texttt{a1} & \quad \text{when } N = 1, \text{otherwise} \\
\texttt{op(GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, a1, ..., aK),
\texttt{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, aM, ..., aN)) & \quad \text{for any } K \text{ where } 1 < K + 1 = M \leq N.
\end{align}
2 Define \texttt{GENERALIZED\_SUM}(op, a1, ..., aN) as \texttt{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, b1, ..., bN), where b1, ..., bN may be any permutation of a1, ..., aN.

25.10.2 Accumulate [accumulate]
template<class InputIterator, class T>
constexpr T accumulate(InputIterator first, InputIterator last, T init);
template<class InputIterator, class T, class BinaryOperation>
constexpr T accumulate(InputIterator first, InputIterator last, T init, BinaryOperation binary_op);

Preconditions: T meets the \texttt{Cpp17CopyConstructible} (Table 29) and \texttt{Cpp17CopyAssignable} (Table 31) requirements. In the range \texttt{[first, last]}, \texttt{binary_op} neither modifies elements nor invalidates iterators or subranges.\[235\]
Effects: Computes its result by initializing the accumulator \texttt{acc} with the initial value \texttt{init} and then modifies it with \texttt{acc = std::move(acc) + *i} or \texttt{acc = binary_op(std::move(acc), *i)} for every iterator \texttt{i} in the range \texttt{[first, last)} in order.\[236\]

25.10.3 Reduce [reduce]
template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::value_type reduce(InputIterator first, InputIterator last);

Effects: Equivalent to:
\begin{verbatim}
return reduce(first, last,
    typename iterator_traits<InputIterator>::value_type());
\end{verbatim}

\[235\] The use of fully closed ranges is intentional.
\[236\] \texttt{accumulate} is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of defining the result of reduction on an empty sequence by always requiring an initial value.
template<class ExecutionPolicy, class ForwardIterator>
    typename iterator_traits<ForwardIterator>::value_type
    reduce(ExecutionPolicy&& exec,
           ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:
    return reduce(std::forward<ExecutionPolicy>(exec), first, last,
                   typename iterator_traits<ForwardIterator>::value_type{});

template<class InputIterator, class T>
    constexpr T reduce(InputIterator first, InputIterator last, T init);

Effects: Equivalent to:
    return reduce(first, last, init, plus<>());

template<class ExecutionPolicy, class ForwardIterator, class T>
    T reduce(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last, T init);

Effects: Equivalent to:
    return reduce(std::forward<ExecutionPolicy>(exec), first, last, init, plus<>());

template<class InputIterator, class T, class BinaryOperation>
    constexpr T reduce(InputIterator first, InputIterator last, T init,
                        BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator, class T, class BinaryOperation>
    T reduce(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last, T init,
             BinaryOperation binary_op);

Mandates: All of
    — binary_op(init, *first),
    — binary_op(*first, init),
    — binary_op(init, init), and
    — binary_op(*first, *first)
are convertible to T.

Preconditions:
    — T meets the Cpp17MoveConstructible (Table 28) requirements.
    — binary_op neither invalidates iterators or subranges, nor modifies elements in the range [first, last].

Returns: GENERALIZED_SUM(binary_op, init, *i, ...) for every i in [first, last).

Complexity: O(last - first) applications of binary_op.

Note: The difference between reduce and accumulate is that reduce applies binary_op in an unspecified order, which yields a nondeterministic result for non-associative or non-commutative binary_op such as floating-point addition. — end note

25.10.4 Inner product

template<class InputIterator1, class InputIterator2, class T>
    constexpr T inner_product(InputIterator1 first1, InputIterator1 last1,
                                InputIterator2 first2, T init);

template<class InputIterator1, class InputIterator2, class T,
         class BinaryOperation1, class BinaryOperation2>
    constexpr T inner_product(InputIterator1 first1, InputIterator1 last1,
                                InputIterator2 first2, T init,
                                BinaryOperation1 binary_op1,
                                BinaryOperation2 binary_op2);

Preconditions: T meets the Cpp17CopyConstructible (Table 29) and Cpp17CopyAssignble (Table 31) requirements. In the ranges [first1, last1] and [first2, first2 + (last1 - first1)] binary_op1 and
§ 25.10.5 Transform reduce [transform.reduce]

```cpp
template<class InputIterator1, class InputIterator2, class T>
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init);
```

**Effects:**
- Equivalent to:
  ```cpp
  return transform_reduce(first1, last1, first2, init, plus<>(), multiplies<>());
  ```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
T transform_reduce(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, T init);
```

**Effects:**
- Equivalent to:
  ```cpp
  return transform_reduce(std::forward<ExecutionPolicy>(exec), first1, last1, first2, init, plus<>(), multiplies<>());
  ```

```cpp
template<class InputIterator1, class InputIterator2, class T, class BinaryOperation1, class BinaryOperation2>
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init, BinaryOperation1 binary_op1, BinaryOperation2 binary_op2);
```

**Mandates:**
- All of
  1. (3.1) `binary_op1(init, init)`
  2. (3.2) `binary_op1(init, binary_op2(*first1, *first2))`
  3. (3.3) `binary_op1(binary_op2(*first1, *first2), init)`
  4. (3.4) `binary_op1(binary_op2(*first1, *first2), binary_op2(*first1, *first2))`

are convertible to `T`.

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T, class BinaryOperation1, class BinaryOperation2>
T transform_reduce(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, T init, BinaryOperation1 binary_op1, BinaryOperation2 binary_op2);
```

**Preconditions:**
- (4.1) `T` meets the `Cpp17MoveConstructible` (Table 28) requirements.
- (4.2) Neither `binary_op1` nor `binary_op2` invalidates subranges, nor modifies elements in the ranges `[first1, last1)` and `[first2, first2 + (last1 - first1))`.

**Returns:**
- `GENERALIZED_SUM(binary_op1, init, binary_op2(*i, *(first2 + (i - first1))), ...)` for every iterator `i` in `[first1, last1)`. (1)

[25.10.5] The use of fully closed ranges is intentional.
Complexity: $O(\text{last1} - \text{first1})$ applications each of binary_op1 and binary_op2.

```cpp
template<class InputIterator, class T,
    class BinaryOperation, class UnaryOperation>
constexpr T transform_reduce(InputIterator first, InputIterator last, T init,
    BinaryOperation binary_op, UnaryOperation unary_op);
```

```cpp
template<class ExecutionPolicy,
    class ForwardIterator, class T,
    class BinaryOperation, class UnaryOperation>
T transform_reduce(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    T init, BinaryOperation binary_op, UnaryOperation unary_op);
```

Mandates: All of

1. binary_op(init, init),
2. binary_op(init, unary_op(*first)),
3. binary_op(unary_op(*first), init), and
4. binary_op(unary_op(*first), unary_op(*first))

are convertible to T.

Preconditions:

1. T meets the Cpp17MoveConstructible (Table 28) requirements.
2. Neither unary_op nor binary_op invalidates subranges, nor modifies elements in the range [first, last].

Returns:

```
GENERALIZED_SUM(binary_op, init, unary_op(*i), ...)
```

for every iterator i in [first, last).

Complexity: $O(\text{last} - \text{first})$ applications each of unary_op and binary_op.

[Note: transform_reduce does not apply unary_op to init. — end note]

---

25.10.6 Partial sum

```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator partial_sum(InputIterator first, InputIterator last,
    OutputIterator result);
```

```cpp
template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator partial_sum(InputIterator first, InputIterator last,
    OutputIterator result, BinaryOperation binary_op);
```

Mandates: InputIterator’s value type is constructible from *first. The result of the expression std::move(acc) + *i or binary_op(std::move(acc), *i) is implicitly convertible to InputIterator’s value type. acc is writable (23.3.1) to result.

Preconditions: In the ranges [first, last] and [result, result + (last - first)] binary_op neither modifies elements nor invalidates iterators or subranges.\(^{238}\)

Effects: For a non-empty range, the function creates an accumulator acc whose type is InputIterator’s value type, initializes it with *first, and assigns the result to *result. For every iterator i in [first + 1, last) in order, acc is then modified by acc = std::move(acc) + *i or acc = binary_op(std::move(acc), *i) and the result is assigned to *result + (i - first)).

Returns: result + (last - first).

Complexity: Exactly (last - first) - 1 applications of the binary operation.

Remarks: result may be equal to first.

\(^{238}\) The use of fully closed ranges is intentional.
25.10.7 Exclusive scan

template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
exclusive_scan(InputIterator first, InputIterator last,
               OutputIterator result, T init);

Effects: Equivalent to:
return exclusive_scan(first, last, result, init, plus<>());

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
exclusive_scan(ExecutionPolicy&& exec,
               ForwardIterator1 first, ForwardIterator1 last,
               ForwardIterator2 result, T init);

Effects: Equivalent to:
return exclusive_scan(std::forward<ExecutionPolicy>(exec),
                      first, last, result, init, plus<>());

template<class InputIterator, class OutputIterator, class T, class BinaryOperation>
constexpr OutputIterator
exclusive_scan(InputIterator first, InputIterator last,
               OutputIterator result, T init, BinaryOperation binary_op);

template<class ExecutionPolicy,
         class ForwardIterator1, class ForwardIterator2, class T, class BinaryOperation>
ForwardIterator2
exclusive_scan(ExecutionPolicy&& exec,
               ForwardIterator1 first, ForwardIterator1 last,
               ForwardIterator2 result, T init, BinaryOperation binary_op);

Mandates: All of

- binary_op(init, init),
- binary_op(init, *first), and
- binary_op(*first, *first)

are convertible to T.

Preconditions:

- T meets the Cpp17MoveConstructible (Table 28) requirements.

- binary_op neither invalidates iterators or subranges, nor modifies elements in the ranges [first, last] or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of:

\[
\text{GENERALIZED_NONCOMMUTATIVE_SUM(}
\text{binary_op, init, *(first + 0), *(first + 1), ..., *(first + K - 1))}
\]

Returns: The end of the resulting range beginning at result.

Complexity: \(\Theta(last - first)\) applications of binary_op.

Remarks: result may be equal to first.

[Note: The difference between exclusive_scan and inclusive_scan is that exclusive_scan excludes the \(i^{th}\) input element from the \(i^{th}\) sum. If binary_op is not mathematically associative, the behavior of exclusive_scan may be nondeterministic. — end note]

25.10.8 Inclusive scan

template<class InputIterator, class OutputIterator>
constexpr OutputIterator
inclusive_scan(InputIterator first, InputIterator last,
               OutputIterator result);

Effects: Equivalent to:
return inclusive_scan(first, last, result, plus<>());
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result);

Effects: Equivalent to:
return inclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, plus<>());

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
inclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result, BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryOperation>
ForwardIterator2
inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result, BinaryOperation binary_op);

Let U be the value type of decltype(first).

Mandates: If init is provided, all of

- binary_op(init, init),
- binary_op(init, *first), and
- binary_op(*first, *first)

are convertible to T; otherwise, binary_op(*first, *first) is convertible to U.

Preconditions:

- If init is provided, T meets the Cpp17MoveConstructible (Table 28) requirements; otherwise, U meets the Cpp17MoveConstructible requirements.
- binary_op neither invalidates iterators or subranges, nor modifies elements in the ranges [first, last] or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of

- GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op, init, *(first + 0), *(first + 1), ..., *(first + K))
  if init is provided, or
- GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op, *(first + 0), *(first + 1), ..., *(first + K))
  otherwise.

Returns: The end of the resulting range beginning at result.

Complexity: $O((last - first))$ applications of binary_op.

Remarks: result may be equal to first.

[Note: The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the $i^{th}$ input element in the $i^{th}$ sum. If binary_op is not mathematically associative, the behavior of inclusive_scan may be nondeterministic. — end note]
25.10.9 Transform exclusive scan

template<class InputIterator, class OutputIterator, class T, class BinaryOperation, class UnaryOperation>
constexpr OutputIterator
transform_exclusive_scan(InputIterator first, InputIterator last,
OutputIterator result, T init,
BinaryOperation binary_op, UnaryOperation unary_op);

Mandates: All of
(1.1) binary_op(init, init),
(1.2) binary_op(init, unary_op(*first)), and
(1.3) binary_op(unary_op(*first), unary_op(*first))

are convertible to T.

Preconditions:
(2.1) T meets the Cpp17MoveConstructible (Table 28) requirements.
(2.2) Neither unary_op nor binary_op invalidates iterators or subranges, nor modifies elements in the ranges [first, last) or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of:
GENERALIZED_NONCOMMUTATIVE_SUM
  binary_op, init,
  unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K - 1)))

Returns: The end of the resulting range beginning at result.

Complexity: $O(\text{last} - \text{first})$ applications each of unary_op and binary_op.

Remarks: result may be equal to first.

[Note: The difference between transform_exclusive_scan and transform_inclusive_scan is that transform_exclusive_scan excludes the $i^{\text{th}}$ input element from the $i^{\text{th}}$ sum. If binary_op is not mathematically associative, the behavior of transform_exclusive_scan may be nondeterministic. transform_exclusive_scan does not apply unary_op to init. — end note]

25.10.10 Transform inclusive scan

template<class InputIterator, class OutputIterator, class BinaryOperation, class UnaryOperation>
constexpr OutputIterator
transform_inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result,
BinaryOperation binary_op, UnaryOperation unary_op);

transform_inclusive_scan(ExecutionPolicy&& exec,
  ForwardIterator1 first, ForwardIterator1 last,
  ForwardIterator2 result, T init,
  BinaryOperation binary_op, UnaryOperation unary_op);

transform_inclusive_scan(InputIterator first, InputIterator last,
  class BinaryOperation, class UnaryOperation, class T>
constexpr OutputIterator
transform_inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result,
    BinaryOperation binary_op, UnaryOperation unary_op,
    T init);

template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2,
    class BinaryOperation, class UnaryOperation, class T>
ForwardIterator2
    transform_inclusive_scan(ExecutionPolicy&& exec,
        ForwardIterator1 first, ForwardIterator1 last,
        ForwardIterator2 result,
        BinaryOperation binary_op, UnaryOperation unary_op,
        T init);

Let U be the value type of decltype(first).

Mandates: If init is provided, all of

(2.1) binary_op(init, init),
(2.2) binary_op(init, unary_op(*first)), and
(2.3) binary_op(unary_op(*first), unary_op(*first))

are convertible to T; otherwise, binary_op(unary_op(*first), unary_op(*first)) is convertible to U.

Preconditions:

(3.1) If init is provided, T meets the Cpp17MoveConstructible (Table 28) requirements; otherwise, U meets the Cpp17MoveConstructible requirements.
(3.2) Neither unary_op nor binary_op invalidates iterators or subranges, nor modifies elements in the ranges [first, last] or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of

(4.1) \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(
    binary_op, init,
    unary_op(*((first + 0)), unary_op(*((first + 1)), ..., unary_op(*((first + K))))
) if init is provided, or
(4.2) \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(
    binary_op,
    unary_op(*((first + 0)), unary_op(*((first + 1)), ..., unary_op(*((first + K))))
) otherwise.

Returns: The end of the resulting range beginning at result.

Complexity: \(O(\text{last} - \text{first})\) applications each of unary_op and binary_op.

Remarks: result may be equal to first.

[Note: The difference between transform_exclusive_scan and transform_inclusive_scan is that transform_inclusive_scan includes the \(i\)th input element in the \(i\)th sum. If binary_op is not mathematically associative, the behavior of transform_inclusive_scan may be nondeterministic. transform_inclusive_scan does not apply unary_op to init. — end note]

25.10.11 Adjacent difference

template<class InputIterator, class OutputIterator>
constexpr OutputIterator
    adjacent_difference(InputIterator first, InputIterator last,
                        OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
    adjacent_difference(ExecutionPolicy&& exec,
                        ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
    adjacent_difference(InputIterator first, InputIterator last,
                        OutputIterator result, BinaryOperation binary_op);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,  
  class BinaryOperation>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
   ForwardIterator1 first, ForwardIterator1 last,  
   ForwardIterator2 result, BinaryOperation binary_op);

Let T be the value type of decltype(first). For the overloads that do not take an argument binary_op, let binary_op be an lvalue that denotes an object of type minus<>.

Mandates:
(2.1) For the overloads with no ExecutionPolicy, T is constructible from *first. acc (defined below) is writable(23.3.1) to the result output iterator. The result of the expression binary_op(val, std::move(acc)) is writable to result.
(2.2) For the overloads with an ExecutionPolicy, the result of the expressions binary_op(*first, *first) and *first are writable to result.

Preconditions:
(1.1) For the overloads with no ExecutionPolicy, T meets the Cpp17MoveAssignable (Table 30) requirements.
(1.2) For all overloads, in the ranges [first, last] and [result, result + (last - first)], binary_op neither modifies elements nor invalidate iterators or subranges.\footnote{The use of fully closed ranges is intentional.}

Effects: For the overloads with no ExecutionPolicy and a non-empty range, the function creates an accumulator acc of type T, initializes it with *first, and assigns the result to *result. For every iterator i in [first + 1, last) in order, creates an object val whose type is T, initializes it with *i, computes binary_op(val, std::move(acc)), assigns the result to *(result + (1 - first)), and move assigns from val to acc.

For the overloads with an ExecutionPolicy and a non-empty range, performs *result = *first. Then, for every d in [1, last - first - 1], performs *(result + d) = binary_op(*(first + d), *(first + (d - 1))).

Returns: result + (last - first).

Complexity: Exactly last - first - 1 applications of the binary operation.

Remarks: For the overloads with no ExecutionPolicy, result may be equal to first. For the overloads with an ExecutionPolicy, the ranges [first, last) and [result, result + (last - first)) shall not overlap.

---

25.10.12 Iota
[numeric.iota]

template<class ForwardIterator, class T>
constexpr void iota(ForwardIterator first, ForwardIterator last, T value);

Mandates: T is convertible to ForwardIterator’s value type. The expression ++val, where val has type T, is well-formed.

Effects: For each element referred to by the iterator i in the range [first, last), assigns *i = value and increments value as if by ++value.

Complexity: Exactly last - first increments and assignments.

---

25.10.13 Greatest common divisor
[numeric.ops.gcd]

template<class M, class N>
constexpr common_type_t<M,N> gcd(M m, N n);

Mandates: M and N both are integer types other than cv bool.

Preconditions: |m| and |n| are representable as a value of common_type_t<M, N>. [Note: These requirements ensure, for example, that gcd(m, m) = |m| is representable as a value of type M. — end note]

Returns: Zero when m and n are both zero. Otherwise, returns the greatest common divisor of |m| and |n|.

Throws: Nothing.
25.10.14 Least common multiple

```cpp
template<class M, class N>
constexpr common_type_t<M,N> lcm(M m, N n);
```

1. **Mandates:** `M` and `N` both are integer types other than `cv bool`.
2. **Preconditions:** `|m|` and `|n|` are representable as a value of `common_type_t<M, N>`. The least common multiple of `|m|` and `|n|` is representable as a value of type `common_type_t<M,N>`.
3. **Returns:** Zero when either `m` or `n` is zero. Otherwise, returns the least common multiple of `|m|` and `|n|`.
4. **Throws:** Nothing.

25.10.15 Midpoint

```cpp
template<class T>
constexpr T midpoint(T a, T b) noexcept;
```

1. **Constraints:** `T` is an arithmetic type other than `bool`.
2. **Returns:** Half the sum of `a` and `b`. If `T` is an integer type and the sum is odd, the result is rounded towards `a`.
3. **Remarks:** No overflow occurs. If `T` is a floating-point type, at most one inexact operation occurs.

```cpp
template<class T>
constexpr T* midpoint(T* a, T* b);
```

1. **Constraints:** `T` is an object type.
2. **Mandates:** `T` is a complete type.
3. **Preconditions:** `a` and `b` point to, respectively, elements `i` and `j` of the same array object `x`. [Note: As specified in 6.8.2, an object that is not an array element is considered to belong to a single-element array for this purpose and a pointer past the last element of an array of `n` elements is considered to be equivalent to a pointer to a hypothetical array element `n` for this purpose. — end note]
4. **Returns:** A pointer to array element `i + \frac{j - i}{2}` of `x`, where the result of the division is truncated towards zero.

25.11 Specialized `<memory>` algorithms

The contents specified in this subclause 25.11 are declared in the header `<memory>` (20.10.2).

2. Unless otherwise specified, if an exception is thrown in the following algorithms, objects constructed by a placement `new-expression` (7.6.2.7) are destroyed in an unspecified order before allowing the exception to propagate.

3. [Note: When invoked on ranges of potentially-overlapping subobjects (6.7.2), the algorithms specified in this subclause 25.11 result in undefined behavior. — end note]

4. Some algorithms specified in this Clause make use of the exposition-only function `voidify`:

```cpp
template<class T>
constexpr void* voidify(T& obj) noexcept {
    return const_cast<void*>(static_cast<const volatile void*>(addressof(obj)));
}
```

25.11.1 Special memory concepts

Some algorithms in this subclause are constrained with the following exposition-only concepts:

```cpp
template<class I>
concept no-throw-input-iterator = // exposition only
    input_iterator<I> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<remove_cvref_t<iter_reference_t<I>>, iter_value_t<I>>;
```

1. A type `I` models `no-throw-input-iterator` only if no exceptions are thrown from increment, copy construction, move construction, copy assignment, move assignment, or indirection through valid iterators.
2. [Note: This concept allows some `input_iterator` (23.3.4.9) operations to throw exceptions. — end note]
template<class S, class I>
concept no-throw-sentinel-for = sentinel_for<S, I>; // exposition only

Types S and I model no-throw-sentinel-for only if no exceptions are thrown from copy construction, move construction, copy assignment, move assignment, or comparisons between valid values of type I and S.

[Note: This concept allows some sentinel_for (23.3.4.7) operations to throw exceptions. — end note]

template<class R>
concept no-throw-input-range = // exposition only
range<R> &&
no-throw-input-iterator<iterator_t<R>> &&
no-throw-sentinel-for<sentinel_t<R>, iterator_t<R>>;

A type R models no-throw-input-range only if no exceptions are thrown from calls to ranges::begin and ranges::end on an object of type R.

template<class I>
concept no-throw-forward-iterator = // exposition only
no-throw-input-iterator<I> &&
forward_iterator<I> &&
no-throw-sentinel-for<I, I>;

[Note: This concept allows some forward_iterator (23.3.4.11) operations to throw exceptions. — end note]

template<class R>
concept no-throw-forward-range = // exposition only
no-throw-input-range<R> &&
no-throw-forward-iterator<iterator_t<R>>;

### 25.11.2 uninitialized_default_construct

[uninitialized.construct.default]

template<class NoThrowForwardIterator>
void uninitialized_default_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);

**Effects:** Equivalent to:

for (; first != last; ++first)
  ::new (voidify(*first))
  typename iterator_traits<NoThrowForwardIterator>::value_type;

namespace ranges {
  template<no-throw-forward-iterator I, no-throw-sentinel-for<I> S>
  requires default_initializable<iter_value_t<I>>
  I uninitialized_default_construct(I first, S last);
  template<no-throw-forward-range R>
  requires default_initializable<range_value_t<R>>
  borrowed_iterator_t<R> uninitialized_default_construct(R&& r);
}

**Effects:** Equivalent to:

for (; first != last; ++first)
  ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>;
  return first;

namespace ranges {
  template<class NoThrowForwardIterator, class Size>
  NoThrowForwardIterator uninitialized_default_construct_n(NoThrowForwardIterator first, Size n);

  **Effects:** Equivalent to:

  for (; n > 0; (void)++first, --n)
    ::new (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type;
    return first;

  namespace ranges {
    template<no-throw-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_default_construct_n(I first, iter_difference_t<I> n);
  }

  § 25.11.2
Effects: Equivalent to:

\[
\text{return uninitialized_default_construct(counted_iterator(first, n),}
\text{default_sentinel).base();}
\]

25.11.3 uninitialized_value_construct

```cpp
template<class NoThrowForwardIterator>
void uninitialized_value_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);
```

Effects: Equivalent to:

```cpp
for (; first != last; ++first)
    ::new (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type();
```

namespace ranges {
    template<
        no-throw-forward-iterator I,
        no-throw-sentinel-for<I> S>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct(I first, S last);
    template<
        no-throw-forward-range R>
    requires default_initializable<range_value_t<R>>
    borrowed_iterator_t<R> uninitialized_value_construct(R&& r);
}

Effects: Equivalent to:

```cpp
for (; first != last; ++first)
    ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>();
    return first;
```

template<class NoThrowForwardIterator, class Size>
NoThrowForwardIterator uninitialized_value_construct_n(NoThrowForwardIterator first, Size n);

Effects: Equivalent to:

```cpp
for (; n > 0; (void)++first, --n)
    ::new (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type();
    return first;
```

namespace ranges {
    template<
        no-throw-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct_n(I first, iter_difference_t<I> n);
}

Effects: Equivalent to:

\[
\text{return uninitialized_value_construct(counted_iterator(first, n),}
\text{default_sentinel).base();}
\]

25.11.4 uninitialized_copy

```cpp
template<class InputIterator, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
    NoThrowForwardIterator result);
```

Preconditions: result + [0, (last - first)) does not overlap with [first, last).

Effects: Equivalent to:

```cpp
for (; first != last; ++result, (void)++first)
    ::new (voidify(*result))
    typename iterator_traits<NoThrowForwardIterator>::value_type(*first);
```

Returns: result.
namespace ranges {
    template<input_iterator I, sentinel_for<I> S1,
        no-throw-forward_iterator O, no-throw-sentinel-for<O> S2>
        requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
    uninitialized_copy_result<I, O>
        uninitialized_copy(I ifirst, S1 ilast, O ofirst, S2 olast);
    template<input_range IR,
        no-throw-forward_range OR>
        requires constructible_from<range_value_t<OR>, range_reference_t<IR>>
    uninitialized_copy_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
        uninitialized_copy(IR&& in_range, OR&& out_range);
}

4 Preconditions: [ofirst, olast) does not overlap with [ifirst, ilast).

5 Effects: Equivalent to:
    for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst) {
        ::new (voidify(*ofirst)) remove_reference_t<iter_reference_t<O>>(*ifirst);
    }
    return {std::move(ifirst), ofirst};

6 Preconditions: result + [0, n) does not overlap with first + [0, n).

7 Effects: Equivalent to:
    for ( ; n > 0; ++result, (void) ++first, --n) {
        ::new (voidify(*result))
            typename iterator_traits<NoThrowForwardIterator>::value_type(*first);
    }

8 Returns: result.

namespace ranges {
    template<input_iterator I, no-throw-forward_iterator O, no-throw-sentinel-for<O> S>
        requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
    uninitialized_copy_n_result<I, O>
        uninitialized_copy_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}

9 Preconditions: [ofirst, olast) does not overlap with ifirst + [0, n).

10 Effects: Equivalent to:
    auto t = uninitialized_copy(counted_iterator(ifirst, n),
        default_sentinel, ofirst, olast);
    return {std::move(t.in).base(), t.out};

25.11.5 uninitialized_move
[uninitialized.move]

template<class InputIterator, class NoThrowForwardIterator>
    NoThrowForwardIterator uninitialized_move(InputIterator first, InputIterator last,
        NoThrowForwardIterator result);

1 Preconditions: result + [0, (last - first)) does not overlap with [first, last).

2 Effects: Equivalent to:
    for (; first != last; (void)++result, ++first) {
        ::new (voidify(*result))
            typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
    return result;

namespace ranges {
    template<input_iterator I, sentinel_for<I> S1,
        no-throw-forward_iterator O, no-throw-sentinel-for<O> S2>
        requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
    uninitialized_move_result<I, O>
        uninitialized_move(I ifirst, S1 ilast, O ofirst, S2 olast);
template<input_range IR, no-throw-forward-range OR>
uninitialized_move_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
uninitialized_move(IR&& in_range, OR&& out_range);

3 Preconditions: [ofirst, olast) does not overlap with [ifirst, ilast).

4 Effects: Equivalent to:
   for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst) {
     ::new (voidify(*ofirst))
     remove_reference_t<iter_reference_t<O>>(ranges::iter_move(ifirst));
   }
   return {std::move(ifirst), ofirst};

5 [Note: If an exception is thrown, some objects in the range [first, last) are left in a valid, but unspecified state. — end note]

template<class InputIterator, class Size, class NoThrowForwardIterator>
pair<InputIterator, NoThrowForwardIterator>
uninitialized_move_n(InputIterator first, Size n, NoThrowForwardIterator result);

6 Preconditions: result + [0, n) does not overlap with first + [0, n).

7 Effects: Equivalent to:
   for (; n > 0; ++result, (void) ++first, --n)
     ::new (voidify(*result))
     typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
   return {first, result};

namespace ranges {
  template<input_iterator I, no-throw-forward-iterator O, no-throw-sentinel-for<O> S>
  requires constructible_from<iter_value_t<O>, iter_rvalue_reference_t<I>>
  uninitialized_move_n_result<I, O>
  uninitialized_move_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}

8 Preconditions: [ofirst, olast) does not overlap with ifirst + [0, n).

9 Effects: Equivalent to:
   auto t = uninitialized_move(counted_iterator(ifirst, n),
     default_sentinel, ofirst, olast);
   return {std::move(t.in).base(), t.out};

10 [Note: If an exception is thrown, some objects in the range first + [0, n) are left in a valid but unspecified state. — end note]

25.11.6 uninitialized_fill

template<class NoThrowForwardIterator, class T>
void uninitialized_fill(NoThrowForwardIterator first, NoThrowForwardIterator last, const T& x);

1 Effects: Equivalent to:
   for (; first != last; ++first)
     ::new (voidify(*first))
     typename iterator_traits<NoThrowForwardIterator>::value_type(x);

namespace ranges {
  template<no-throw-forward-iterator I, no-throw-sentinel-for<I> S, class T>
  requires constructible_from<iter_value_t<I>, const T&>
  I uninitialized_fill(I first, S last, const T& x);
  template<no-throw-forward-range R, class T>
  requires constructible_from<range_value_t<R>, const T&>
  borrowed_iterator_t<R> uninitialized_fill(R&& r, const T& x);
}

2 Effects: Equivalent to:
for (; first != last; ++first) {
    ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>(x);
} return first;

template<class NoThrowForwardIterator, class Size, class T>
NoThrowForwardIterator uninitialized_fill_n(NoThrowForwardIterator first, Size n, const T& x);

Effects: Equivalent to:
for (; n--; ++first)
    ::new (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type(x);
return first;

namespace ranges {
    template<no-throw-forward-iterator I, class T>
    requires constructible_from<iter_value_t<I>, const T&>
    I uninitialized_fill_n(I first, iter_difference_t<I> n, const T& x);
}

Effects: Equivalent to:
return uninitialized_fill(counted_iterator(first, n), default_sentinel, x).base();

25.11.7 construct_at

template<class T, class... Args>
constexpr T* construct_at(T* location, Args&&... args);

namespace ranges {
    template<class T, class... Args>
    constexpr T* construct_at(T* location, Args&&... args);
}

Constraints: The expression ::new (declval<void*>()) T(declval<Args>()...) is well-formed when treated as an unevaluated operand.

Effects: Equivalent to:
return ::new (voidify(*location)) T(std::forward<Args>(args)...);

25.11.8 destroy

template<class T>
constexpr void destroy_at(T* location);

namespace ranges {
    template<destructible T>
    constexpr void destroy_at(T* location) noexcept;
}

Effects:

1. If T is an array type, equivalent to destroy(begin(*location), end(*location)).
2. Otherwise, equivalent to location->~T().

template<class NoThrowForwardIterator>
constexpr void destroy(NoThrowForwardIterator first, NoThrowForwardIterator last);

Effects: Equivalent to:
for (; first != last; ++first)
    destroy_at(addressof(*first));

namespace ranges {
    template<no-throw-input-iterator I, no-throw-sentinel-for<I> S>
    requires destructible<iter_value_t<I>>
    constexpr I destroy(I first, S last) noexcept;
}
template<no-throw-input-range R>
requires destructible<range_value_t<R>>
constexpr borrowed_iterator_t<R> destroy(R&& r) noexcept;

Effects: Equivalent to:
for (; first != last; ++first)
    destroy_at(addressof(*first));
return first;

template<class NoThrowForwardIterator, class Size>
constexpr NoThrowForwardIterator destroy_n(NoThrowForwardIterator first, Size n);

Effects: Equivalent to:
for (; n > 0; (void)++first, --n)
    destroy_at(addressof(*first));
return first;

namespace ranges {
    template<no-throw-input-iterator I>
    requires destructible<iter_value_t<I>>
    constexpr I destroy_n(I first, iter_difference_t<I> n) noexcept;
}

Effects: Equivalent to:
return destroy(counted_iterator(first, n), default_sentinel).base();

25.12 C library algorithms

[Note: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

void* bsearch(const void* key, const void* base, size_t nmemb, size_t size,
                  c-compare-pred* compar);
void* bsearch(const void* key, const void* base, size_t nmemb, size_t size,
                  compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size, c-compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size, compare-pred* compar);

Preconditions: The objects in the array pointed to by base are of trivial type.

Effects: These functions have the semantics specified in the C standard library.

Throws: Any exception thrown by compar (16.5.5.13).

See also: ISO C 7.22.5.
26 Numerics library [numerics]

26.1 General [numerics.general]

1 This Clause describes components that C++ programs may use to perform seminumerical operations.

2 The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, and mathematical constants and functions for floating-point types, as summarized in Table 92.

Table 92: Numerics library summary [tab:numerics.summary]

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>26.2 Requirements</td>
<td></td>

</tbody>
</table>

26.2 Numeric type requirements [numeric.requirements]

1 The complex and valarray components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a numeric type. A numeric type is a cv-unqualified object type T that meets the `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, `Cpp17CopyAssignable`, and `Cpp17Destructible` requirements (16.5.3.1).240

2 If any operation on T throws an exception the effects are undefined.

3 In addition, many member and related functions of `valarray<T>` can be successfully instantiated and will exhibit well-defined behavior if and only if T meets additional requirements specified for each such member or related function.

4 [Example: It is valid to instantiate `valarray<complex>`, but `operator()` will not be successfully instantiated for `valarray<complex>` operands, since `complex` does not have any ordering operators. — end example]

26.3 The floating-point environment [cfenv]

26.3.1 Header <cfenv> synopsis [cfenv.syn]

```c
#define FE_ALL_EXCEPT see below   // optional
#define FE_DIVBYZERO see below     // optional
#define FE_INEXACT see below       // optional
#define FE_INVALID see below       // optional
#define FE_OVERFLOW see below      // optional
#define FE_UNDERFLOW see below     // optional

#define FE_DOWNWARD see below      // optional
#define FE_TONEAREST see below     // optional
#define FE_TOWARDZERO see below    // optional
#define FE_UPWARD see below        // optional

#define FE_DFL_ENV see below
```

---

240 In other words, value types. These include arithmetic types, pointers, the library class `complex`, and instantiations of `valarray` for value types.
namespace std {
  // types
  using fenv_t = object type;
  using fexcept_t = integer type;
  // functions
  int feclearexcept(int except);
  int fegetexceptflag(fexcept_t* pflag, int except);
  int feraiseexcept(int except);
  int fesetexceptflag(const fexcept_t* pflag, int except);
  int fetestexcept(int except);
  int fegetround();
  int fesetround(int mode);
  int fegetenv(fenv_t* penv);
  int feholdexcept(fenv_t* penv);
  int fesetenv(const fenv_t* penv);
  int feupdateenv(const fenv_t* penv);
}

1 The contents and meaning of the header <cfenv> are the same as the C standard library header <fenv.h>. [Note: This document does not require an implementation to support the FENV_ACCESS pragma; it is implementation-defined (15.9) whether the pragma is supported. As a consequence, it is implementation-defined whether these functions can be used to test floating-point status flags, set floating-point control modes, or run under non-default mode settings. If the pragma is used to enable control over the floating-point environment, this document does not specify the effect on floating-point evaluation in constant expressions. — end note]

2 The floating-point environment has thread storage duration (6.7.5.2). The initial state for a thread’s floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding thread object (32.4.2) or jthread object (32.4.3) at the time it constructed the object. [Note: That is, the child thread gets the floating-point state of the parent thread at the time of the child’s creation. — end note]

3 A separate floating-point environment is maintained for each thread. Each function accesses the environment corresponding to its calling thread.

See also: ISO C 7.6

26.4 Complex numbers [complex.numbers]

1 The header <complex> defines a class template, and numerous functions for representing and manipulating complex numbers.

2 The effect of instantiating the template complex for any type other than float, double, or long double is unspecified. The specializations complex<float>, complex<double>, and complex<long double> are literal types (6.8).

3 If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

4 If \( z \) is an lvalue of type cv complex<\( T \)>, then:

\( \begin{align*}
  &\text{(4.1)} \quad \text{the expression reinterpret_cast<cv T(&)[2]>(z)} \text{ is well-formed}, \\
  &\text{(4.2)} \quad \text{reinterpret_cast<cv T(&)[2]>(z)[0]} \text{ designates the real part of } z, \text{ and} \\
  &\text{(4.3)} \quad \text{reinterpret_cast<cv T(&)[2]>(z)[1]} \text{ designates the imaginary part of } z.
\end{align*} \\
\)

Moreover, if \( a \) is an expression of type cv complex<\( T \)*> and the expression \( a[i] \) is well-defined for an integer expression \( i \), then:

\( \begin{align*}
  &\text{(4.4) \quad \text{reinterpret_cast<cv T*>(a)[2*i]} \text{ designates the real part of } a[i], \text{ and} \\
  &\text{(4.5)} \quad \text{reinterpret_cast<cv T*>(a)[2*i + 1]} \text{ designates the imaginary part of } a[i].
\end{align*} \)

26.4.1 Header <complex> synopsis [complex.syn]

namespace std {
    // 26.4.2, class template complex
    template<class T> class complex;
// 26.4.3, specializations
template<> class complex<float>;
template<> class complex<double>;
template<> class complex<long double>;

// 26.4.6, operators
template<class T> constexpr complex<T> operator+(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator+(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator+(const T&, const complex<T>&);

template<class T> constexpr complex<T> operator-(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&, const T&);

template<class T> complex<T> atanh(const complex<T>&);

template<class T> complex<T> cos (const complex<T>&);

template<class T> complex<T> cosh (const complex<T>&);

template<class T> complex<T> exp (const complex<T>&);

template<class T> complex<T> log (const complex<T>&);

template<class T> complex<T> log10(const complex<T>&);

template<class T> complex<T> pow (const complex<T>&, const T&);

template<class T> complex<T> pow (const complex<T>&, const complex<T>&);

template<class T> complex<T> pow (const T&, const complex<T>&);
// 26.4.10, complex literals
inline namespace literals {
  inline namespace complex_literals {
    constexpr complex<long double> operator"il(long double);
    constexpr complex<long double> operator"il(unsigned long long);
    constexpr complex<double> operator"i(long double);
    constexpr complex<double> operator"i(unsigned long long);
    constexpr complex<float> operator"if(long double);
    constexpr complex<float> operator"if(unsigned long long);
  }
}

## 26.4.2 Class template `complex`

The class `complex` describes an object that can store the Cartesian components, `real()` and `imag()`, of a complex number.

### 26.4.3 Specializations

```c++
namespace std {
  template<> class complex<float> {
    public:
      using value_type = float;

      constexpr complex(float re = 0.0f, float im = 0.0f);
      constexpr complex(const complex<float>&) = default;
      constexpr explicit complex(const complex<double>&);
      constexpr explicit complex(const complex<long double>&);
  };
}
```

1 The class `complex` describes an object that can store the Cartesian components, `real()` and `imag()`, of a complex number.
constexpr float real() const;
constexpr void real(float);
constexpr float imag() const;
constexpr void imag(float);

constexpr complex& operator= (float);
constexpr complex& operator+= (float);
constexpr complex& operator-= (float);
constexpr complex& operator*= (float);
constexpr complex& operator/= (float);

constexpr complex& operator=(const complex&);
template<class X> constexpr complex& operator=(const complex<X>&);

};

template<> class complex<double> {
public:
    using value_type = double;

    constexpr complex(double re = 0.0, double im = 0.0);
    constexpr complex(const complex<float>&);
    constexpr complex(const complex<double>&) = default;
    constexpr explicit complex(const complex<long double>&);

    constexpr double real() const;
    constexpr void real(double);
    constexpr double imag() const;
    constexpr void imag(double);

    constexpr complex& operator= (double);
    constexpr complex& operator+= (double);
    constexpr complex& operator-= (double);
    constexpr complex& operator*= (double);
    constexpr complex& operator/= (double);

    constexpr complex& operator=(const complex&);
    template<class X> constexpr complex& operator=(const complex<X>&);

};

template<> class complex<long double> {
public:
    using value_type = long double;

    constexpr complex(long double re = 0.0L, long double im = 0.0L);
    constexpr complex(const complex<float>&);
    constexpr complex(const complex<double>&);

    constexpr long double real() const;
    constexpr void real(long double);
    constexpr long double imag() const;
    constexpr void imag(long double);

    constexpr complex& operator= (long double);
    constexpr complex& operator+= (long double);
    constexpr complex& operator-= (long double);

};
constexpr complex& operator*=(long double);
constexpr complex& operator/=(long double);

constexpr complex& operator=(const complex&);
template<class X> constexpr complex& operator= (const complex<X>&);

template<class X> constexpr complex& operator+=(const complex<X>&);
template<class X> constexpr complex& operator-=(const complex<X>&);
template<class X> constexpr complex& operator*=(const complex<X>&);
template<class X> constexpr complex& operator/=(const complex<X>&);

26.4.4 Member functions

template<class T> constexpr complex(const T& re = T(), const T& im = T());

Postconditions: real() == re && imag() == im is true.

constexpr T real() const;

Returns: The value of the real component.

constexpr void real(T val);

Effects: Assigns val to the real component.

constexpr T imag() const;

Returns: The value of the imaginary component.

constexpr void imag(T val);

Effects: Assigns val to the imaginary component.

26.4.5 Member operators

constexpr complex& operator+=(const T& rhs);

Effects: Adds the scalar value rhs to the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.

constexpr complex& operator-=(const T& rhs);

Effects: Subtracts the scalar value rhs from the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.

constexpr complex& operator*=(const T& rhs);

Effects: Multiplies the scalar value rhs by the complex value *this and stores the result in *this.

Returns: *this.

constexpr complex& operator/=(const T& rhs);

Effects: Divides the scalar value rhs into the complex value *this and stores the result in *this.

Returns: *this.

template<class X> constexpr complex& operator+=(const complex<X>& rhs);

Effects: Adds the complex value rhs to the complex value *this and stores the sum in *this.

Returns: *this.

template<class X> constexpr complex& operator-=(const complex<X>& rhs);

Effects: Subtracts the complex value rhs from the complex value *this and stores the difference in *this.

Returns: *this.
template<class X> constexpr complex& operator*=(const complex<X>& rhs);

Effects: Multiplies the complex value rhs by the complex value *this and stores the product in *this.

Returns: *this.

template<class X> constexpr complex& operator/(const complex<X>& rhs);

Effects: Divides the complex value rhs into the complex value *this and stores the quotient in *this.

Returns: *this.

26.4.6 Non-member operations

[complex.ops]

template<class T> constexpr complex<T> operator+(const complex<T>& lhs);

Returns: complex<T>(lhs).

template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);

template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const T& rhs);

template<class T> constexpr complex<T> operator+(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) += rhs.

template<class T> constexpr complex<T> operator-(const complex<T>& lhs);

template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);

template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const T& rhs);

template<class T> constexpr complex<T> operator-(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) -= rhs.

template<class T> constexpr complex<T> operator/(const complex<T>& lhs, const complex<T>& rhs);

template<class T> constexpr complex<T> operator/(const complex<T>& lhs, const T& rhs);

template<class T> constexpr complex<T> operator/(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) /= rhs.

template<class T> constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);

template<class T> constexpr bool operator==(const complex<T>& lhs, const T& rhs);

Returns: lhs.real() == rhs.real() && lhs.imag() == rhs.imag().

Remarks: The imaginary part is assumed to be T(), or 0.0, for the T arguments.

template<class T, class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, complex<T>& x);

Preconditions: The input values are convertible to T.

Effects: Extracts a complex number x of the form: u, (u), or (u,v), where u is the real part and v is the imaginary part (29.7.4.2).

If bad input is encountered, calls is.setstate(ios_base::failbit) (which may throw ios_base::failure (29.5.5.4)).

Returns: is.

Remarks: This extraction is performed as a series of simpler extractions. Therefore, the skipping of whitespace is specified to be the same for each of the simpler extractions.

template<class T, class charT, class traits>
basic_ostream<charT, traits>& operator<<((basic_ostream<charT, traits>& o, const complex<T>& x));

Effects: Inserts the complex number x onto the stream o as if it were implemented as follows:

basic_ostringstream<charT, traits> s;
s.flags(o.flags());
[Note: In a locale in which comma is used as a decimal point character, the use of comma as a field separator can be ambiguous. Inserting `showpoint` into the output stream forces all outputs to show an explicit decimal point character; as a result, all inserted sequences of complex numbers can be extracted unambiguously. — end note]

### 26.4.7 Value operations

```cpp
template<class T> constexpr T real(const complex<T>& x);
Returns: x.real().
```

```cpp
template<class T> constexpr T imag(const complex<T>& x);
Returns: x.imag().
```

```cpp
template<class T> T abs(const complex<T>& x);
Returns: The magnitude of x.
```

```cpp
template<class T> T arg(const complex<T>& x);
Returns: The phase angle of x, or _atan2_(imag(x), real(x)).
```

```cpp
template<class T> constexpr T norm(const complex<T>& x);
Returns: The squared magnitude of x.
```

```cpp
template<class T> constexpr complex<T> conj(const complex<T>& x);
Returns: The complex conjugate of x.
```

```cpp
template<class T> complex<T> proj(const complex<T>& x);
Returns: The projection of x onto the Riemann sphere.
Remarks: Behaves the same as the C function `cproj`. See also: ISO C 7.3.9.5
```

```cpp
template<class T> complex<T> polar(const T& rho, const T& theta = T());
Preconditions: rho is non-negative and non-NaN. theta is finite.
Returns: The complex value corresponding to a complex number whose magnitude is rho and whose phase angle is theta.
```

### 26.4.8 Transcendentals

```cpp
template<class T> complex<T> acos(const complex<T>& x);
Returns: The complex arc cosine of x.
Remarks: Behaves the same as the C function `cacos`. See also: ISO C 7.3.5.1
```

```cpp
template<class T> complex<T> asin(const complex<T>& x);
Returns: The complex arc sine of x.
Remarks: Behaves the same as the C function `casin`. See also: ISO C 7.3.5.2
```

```cpp
template<class T> complex<T> atan(const complex<T>& x);
Returns: The complex arc tangent of x.
Remarks: Behaves the same as the C function `catan`. See also: ISO C 7.3.5.3
```

```cpp
template<class T> complex<T> acosh(const complex<T>& x);
Remarks: Behaves the same as the C function `cacosh`. See also: ISO C 7.3.6.1
```
template<class T> complex<T> asinh(const complex<T>& x);

Returns: The complex arc hyperbolic sine of x.
Remarks: Behaves the same as the C function casinh. See also: ISO C 7.3.6.2

template<class T> complex<T> atanh(const complex<T>& x);

Returns: The complex arc hyperbolic tangent of x.
Remarks: Behaves the same as the C function catanh. See also: ISO C 7.3.6.3

template<class T> complex<T> cos(const complex<T>& x);

Returns: The complex cosine of x.

template<class T> complex<T> cosh(const complex<T>& x);

Returns: The complex hyperbolic cosine of x.

template<class T> complex<T> exp(const complex<T>& x);

Returns: The complex base-e exponential of x.

template<class T> complex<T> log(const complex<T>& x);

Returns: The complex natural (base-e) logarithm of x. For all x, imag(log(x)) lies in the interval [-π, π].
[Note: The semantics of this function are intended to be the same in C++ as they are for clog in C. — end note]
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> log10(const complex<T>& x);

Returns: The complex common (base-10) logarithm of x, defined as log(x) / log(10).
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> pow(const complex<T>& x, const complex<T>& y);
template<class T> complex<T> pow(const complex<T>& x, const T& y);
template<class T> complex<T> pow(const T& x, const complex<T>& y);

Returns: The complex power of base x raised to the yth power, defined as exp(y * log(x)). The value returned for pow(0, 0) is implementation-defined.
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> sin(const complex<T>& x);

Returns: The complex sine of x.

template<class T> complex<T> sinh(const complex<T>& x);

Returns: The complex hyperbolic sine of x.

template<class T> complex<T> sqrt(const complex<T>& x);

Returns: The complex square root of x, in the range of the right half-plane. [Note: The semantics of this function are intended to be the same in C++ as they are for csqrt in C. — end note]
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> tan(const complex<T>& x);

Returns: The complex tangent of x.

template<class T> complex<T> tanh(const complex<T>& x);

Returns: The complex hyperbolic tangent of x.

26.4.9 Additional overloads

The following function templates shall have additional overloads:

arg
conj
imag
norm
proj
real
where \( \text{norm} \), \( \text{conj} \), \( \text{imag} \), and \( \text{real} \) are constexpr overloads.

The additional overloads shall be sufficient to ensure:

2. The additional overloads shall be sufficient to ensure:

\[ \text{(2.1)} \]
- If the argument has type \( \text{long double} \), then it is effectively cast to \( \text{complex<long double>} \).

\[ \text{(2.2)} \]
- Otherwise, if the argument has type \( \text{double} \) or an integer type, then it is effectively cast to \( \text{complex<double>} \).

\[ \text{(2.3)} \]
- Otherwise, if the argument has type \( \text{float} \), then it is effectively cast to \( \text{complex<float>} \).

3. Function template \( \text{pow} \) shall have additional overloads sufficient to ensure, for a call with at least one argument of type \( \text{complex<T>\rangle} \):

\[ \text{(3.1)} \]
- If either argument has type \( \text{complex<long double>} \) or type \( \text{long double} \), then both arguments are effectively cast to \( \text{complex<long double>} \).

\[ \text{(3.2)} \]
- Otherwise, if either argument has type \( \text{complex<double>} \), \( \text{double} \), or an integer type, then both arguments are effectively cast to \( \text{complex<double>} \).

\[ \text{(3.3)} \]
- Otherwise, if either argument has type \( \text{complex<float>} \) or \( \text{float} \), then both arguments are effectively cast to \( \text{complex<float>} \).

### 26.4.10 Suffixes for complex number literals

This subclause describes literal suffixes for constructing complex number literals. The suffixes \( i \), \( il \), and \( if \) create complex numbers of the types \( \text{complex<double>} \), \( \text{complex<long double>} \), and \( \text{complex<float>} \) respectively, with their imaginary part denoted by the given literal number and the real part being zero.

\begin{align*}
\text{constexpr complex<long double>} & \text{ operator}"\text{il}(	ext{long long } d); \\
\text{constexpr complex<long double>} & \text{ operator}"\text{il}(	ext{unsigned long long } d); \\
\text{constexpr complex<double>} & \text{ operator}"\text{i}(	ext{long long } d); \\
\text{constexpr complex<double>} & \text{ operator}"\text{i}(	ext{unsigned long long } d); \\
\text{constexpr complex<float>} & \text{ operator}"\text{if}(	ext{long long } d); \\
\text{constexpr complex<float>} & \text{ operator}"\text{if}(	ext{unsigned long long } d); 
\end{align*}

\begin{itemize}
\item \( \text{constexpr complex<long double>} \{0.0L, \text{static_cast<long double>}(d)} \} \).
\item \( \text{constexpr complex<double>} \{0.0, \text{static_cast<double>}(d)} \} \).
\item \( \text{constexpr complex<float>} \{0.0f, \text{static_cast<float>}(d)} \} \).
\end{itemize}

### 26.5 Bit manipulation

#### 26.5.1 General

The header \(<\text{bit}>\) provides components to access, manipulate and process both individual bits and bit sequences.

#### 26.5.2 Header \(<\text{bit}>\) synopsis

\begin{verbatim}
namespace std {
// 26.3.4.4, integral powers of 2
template<class T>
\text{constexpr bool has_single_bit(T x) noexcept;}

// 26.5.5, rotating
\text{template<class T>}
\text{[[nodiscard]] constexpr T rotl(T x, int s) noexcept;}
\text{template<class T>}
\text{[[nodiscard]] constexpr T rotr(T x, int s) noexcept;}
\end{verbatim}
// 26.5.6, counting
template<class T>
  constexpr int countl_zero(T x) noexcept;
template<class T>
  constexpr int countl_one(T x) noexcept;
template<class T>
  constexpr int countr_zero(T x) noexcept;
template<class T>
  constexpr int countr_one(T x) noexcept;
template<class T>
  constexpr int popcount(T x) noexcept;

// 26.5.7, endian
enum class endian {
  little = see below,
  big = see below,
  native = see below
};

26.5.3 Function template bit_cast

template<class To, class From>
  constexpr To bit_cast(const From& from) noexcept;

Constraints:
- sizeof(To) == sizeof(From) is true;
- is_trivially_copyable_v<To> is true; and
- is_trivially_copyable_v<From> is true.

Returns: An object of type To. Implicitly creates objects nested within the result (6.7.2). Each bit of the value representation of the result is equal to the corresponding bit in the object representation of from. Padding bits of the result are unspecified. For the result and each object created within it, if there is no value of the object's type corresponding to the value representation produced, the behavior is undefined. If there are multiple such values, which value is produced is unspecified.

Remarks: This function is constexpr if and only if To, From, and the types of all subobjects of To and From are types T such that:
- is_union_v<T> is false;
- is_pointer_v<T> is false;
- is_member_pointer_v<T> is false;
- is_volatile_v<T> is false; and
- T has no non-static data members of reference type.

26.5.4 Integral powers of 2

template<class T>
  constexpr bool has_single_bit(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.1).

Returns: true if x is an integral power of two; false otherwise.

template<class T>
  constexpr T bit_ceil(T x);

Let N be the smallest power of 2 greater than or equal to x.

Constraints: T is an unsigned integer type (6.8.1).

Preconditions: N is representable as a value of type T.

Returns: N.

Throws: Nothing.
Remarks: A function call expression that violates the precondition in the Preconditions: element is not a core constant expression (7.7).

```cpp
template<class T>
constexpr T bit_floor(T x) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Returns: If x == 0, 0; otherwise the maximal value y such that has_single_bit(y) is true and y <= x.

```cpp
template<class T>
constexpr T bit_width(T x) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Returns: If x == 0, 0; otherwise one plus the base-2 logarithm of x, with any fractional part discarded.

### 26.5.5 Rotating

In the following descriptions, let N denote numeric_limits<T>::digits.

```cpp
template<class T>
[[nodiscard]] constexpr T rotl(T x, int s) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Let r be s % N.

Returns: If r is 0, x; if r is positive, \((x << r) | (x >> (N - r))\); if r is negative, rotr(x, -r).

```cpp
template<class T>
[[nodiscard]] constexpr T rotr(T x, int s) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Let r be s % N.

Returns: If r is 0, x; if r is positive, \((x >> r) | (x << (N - r))\); if r is negative, rotl(x, -r).

### 26.5.6 Counting

In the following descriptions, let N denote numeric_limits<T>::digits.

```cpp
template<class T>
constexpr int countl_zero(T x) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Returns: The number of consecutive 0 bits in the value of x, starting from the most significant bit. [Note: Returns N if x == 0. —end note]

```cpp
template<class T>
constexpr int countl_one(T x) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Returns: The number of consecutive 1 bits in the value of x, starting from the most significant bit. [Note: Returns N if x == numeric_limits<T>::max(). —end note]

```cpp
template<class T>
constexpr int countr_zero(T x) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Returns: The number of consecutive 0 bits in the value of x, starting from the least significant bit. [Note: Returns N if x == 0. —end note]

```cpp
template<class T>
constexpr int countr_one(T x) noexcept;
```

Constraints: T is an unsigned integer type (6.8.1).

Returns: The number of consecutive 1 bits in the value of x, starting from the least significant bit. [Note: Returns N if x == numeric_limits<T>::max(). —end note]
template<class T>
constexpr int popcount(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.1).

Returns: The number of 1 bits in the value of x.

26.5.7 Endian

Two common methods of byte ordering in multibyte scalar types are big-endian and little-endian in the execution environment. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage of binary data in which the least significant byte is placed first, with the rest in ascending order. This subclause describes the endianness of the scalar types of the execution environment.

```cpp
eenum class endian {
    little = see below,
    big    = see below,
    native = see below
};
```

If all scalar types have size 1 byte, then all of `endian::little`, `endian::big`, and `endian::native` have the same value. Otherwise, `endian::little` is not equal to `endian::big`. If all scalar types are big-endian, `endian::native` is equal to `endian::big`. If all scalar types are little-endian, `endian::native` is equal to `endian::little`. Otherwise, `endian::native` is not equal to either `endian::big` or `endian::little`.

26.6 Random number generation

This subclause defines a facility for generating (pseudo-)random numbers.

In addition to a few utilities, four categories of entities are described: uniform random bit generators, random number engines, random number engine adaptors, and random number distributions. These categorizations are applicable to types that meet the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated. [Note: These entities are specified in such a way as to permit the binding of any uniform random bit generator object e as the argument to any random number distribution object d, thus producing a zero-argument function object such as given by `bind(d, e)`. — end note]

Each of the entities specified via this subclause has an associated arithmetic type (6.8.1) identified as `result_type`. With T as the `result_type` thus associated with such an entity, that entity is characterized:

1. as `boolean` or equivalently as `boolean-valued`, if T is `bool`;
2. otherwise as `integral` or equivalently as `integer-valued`, if `numeric_limits<T>::is_integer` is `true`;
3. otherwise as `floating-point` or equivalently as `real-valued`.

If integer-valued, an entity may optionally be further characterized as `signed` or `unsigned`, according to `numeric_limits<T>::is_signed`.

Unless otherwise specified, all descriptions of calculations in this subclause use mathematical real numbers.

Throughout this subclause, the operators `bitand`, `bitor`, and `xor` denote the respective conventional bitwise operations. Further:

- the operator `rshift` denotes a bitwise right shift with zero-valued bits appearing in the high bits of the result, and
- the operator `lshiftw` denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo $2^w$.

26.6.1 Header `<random>` synopsis

```cpp
#include <initializer_list>

namespace std {
    // 26.6.2.3, uniform random bit generator requirements
template<class G>
    concept uniform_random_bit_generator = see below;
}

}
26.6.2 Requirements

26.6.2.1 General requirements

Throughout this subclause 26.6, the effect of instantiating a template:

1. that has a template type parameter named Sseq is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of seed sequence (26.6.2.2).
2. that has a template type parameter named URBG is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of uniform random bit generator (26.6.2.3).
3. that has a template type parameter named Engine is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of random number engine (26.6.2.4).
4. that has a template type parameter named RealType is undefined unless the corresponding template argument is cv-unqualified and is one of float, double, or long double.
5. that has a template type parameter named IntType is undefined unless the corresponding template argument is cv-unqualified and is one of short, int, long, long long, unsigned short, unsigned int, unsigned long, or unsigned long long.
6. that has a template type parameter named UIntType is undefined unless the corresponding template argument is cv-unqualified and is one of unsigned short, unsigned int, unsigned long, or unsigned long long.

Throughout this subclause 26.6, phrases of the form "x is an iterator of a specific kind" shall be interpreted as equivalent to the more formal requirement that "x is a value of a type meeting the requirements of the specified iterator type".

Throughout this subclause 26.6, any constructor that can be called with a single argument and that meets a requirement specified in this subclause shall be declared explicit.

26.6.2.2 Seed sequence requirements

A seed sequence is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values $i$, $0 \leq i < 2^{32}$, based on the consumed data. [Note: Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines. — end note]

A class $S$ meets the requirements of a seed sequence if the expressions shown in Table 93 are valid and have the indicated semantics, and if $S$ also meets all other requirements of this subclause 26.6.2.2. In that Table and throughout this subclause:

- $T$ is the type named by $S$'s associated result_type;
- $q$ is a value of $S$ and $r$ is a possibly const value of $S$;
- $ib$ and $ie$ are input iterators with an unsigned integer value_type of at least 32 bits;
- $rb$ and $re$ are mutable random access iterators with an unsigned integer value_type of at least 32 bits;
- $ob$ is an output iterator; and
- $il$ is a value of initializer_list<T>.

<td>O(r.size())</td>
</tr>
</tbody>
</table>

26.6.2.3 Uniform random bit generator requirements

1 A uniform random bit generator $g$ of type $G$ is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned. [Note: The degree to which $g$'s results approximate the ideal is often determined statistically. — end note]

```cpp
#include <random>

template<class G>
concept uniform_random_bit_generator =
    invocable<G&> && unsigned_integral<invoke_result_t<G&>> &&
    requires {
        { G::min() } -> same_as<invoke_result_t<G&>>;
        { G::max() } -> same_as<invoke_result_t<G&>>;
        requires bool_constant<(G::min() < G::max())>::value;
    };
```

2 Let $g$ be an object of type $G$. $G$ models uniform_random_bit_generator only if

- (2.1) $G::\min() \leq g()$
- (2.2) $g() \leq G::\max()$, and
- (2.3) $g()$ has amortized constant complexity.

3 A class $G$ meets the uniform random bit generator requirements if $G$ models uniform_random_bit_generator, invoke_result_t<G&> is an unsigned integer type (6.8.1), and $G$ provides a nested typedef-name result_type that denotes the same type as invoke_result_t<G&>.

26.6.2.4 Random number engine requirements

1 A random number engine (commonly shortened to engine) $e$ of type $E$ is a uniform random bit generator that additionally meets the requirements (e.g., for seeding and for input/output) specified in this subclause.

2 At any given time, $e$ has a state $e_i$ for some integer $i \geq 0$. Upon construction, $e$ has an initial state $e_0$. An engine’s state may be established via a constructor, a seed function, assignment, or a suitable operator>>.

3 $E$'s specification shall define:

- (3.1) the size of $E$’s state in multiples of the size of result_type, given as an integral constant expression;
- (3.2) the transition algorithm TA by which $e$’s state $e_i$ is advanced to its successor state $e_{i+1}$; and
- (3.3) the generation algorithm GA by which an engine’s state is mapped to a value of type result_type.

4 A class $E$ that meets the requirements of a uniform random bit generator (26.6.2.3) also meets the requirements of a random number engine if the expressions shown in Table 94 are valid and have the indicated semantics, and if $E$ also meets all other requirements of this subclause 26.6.2.4. In that Table and throughout this subclause:

\[ \text{§ 26.6.2.4 1132} \]
— $T$ is the type named by $E$'s associated result_type;
— $e$ is a value of $E$, $v$ is an lvalue of $E$, $x$ and $y$ are (possibly const) values of $E$;
— $s$ is a value of $T$;
— $q$ is an lvalue meeting the requirements of a seed sequence (26.6.2.2);
— $z$ is a value of type unsigned long long;
— $os$ is an lvalue of the type of some class template specialization basic_ostream<charT, traits>; and
— $is$ is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where charT and traits are constrained according to Clause 21 and Clause 29.

<table>

<td>Advances $e$'s state $e_i$ to $e_{i+1}$ = $TA(e_i)$ and returns $GA(e_i)$.</td>
<td>per 26.6.2.3</td>
</tr>
<tr>
<td>$e.discard(z)^{242}$</td>
<td>void</td>
<td>Advances $e$'s state $e_i$ to $e_{i+z}$ by any means equivalent to $z$ consecutive calls $e()$.</td>
<td>no worse than the complexity of $z$ consecutive calls $e()$.</td>
</tr>
<tr>
<td>$x == y$</td>
<td>bool</td>
<td>This operator is an equivalence relation. With $S_x$ and $S_y$ as the infinite sequences of values that would be generated by repeated future calls to $x()$ and $y()$, respectively, returns true if $S_x = S_y$; else returns false.</td>
<td>$O(\text{size of state})$</td>
</tr>
<tr>
<td>$x != y$</td>
<td>bool</td>
<td>!(x == y).</td>
<td>$O(\text{size of state})$</td>
</tr>
</tbody>
</table>

241) This constructor (as well as the subsequent corresponding seed() function) may be particularly useful to applications requiring a large number of independent random sequences.

242) This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes $z$ consecutive calls $e()$.

§ 26.6.2.4
Expression | Return type | Pre/post-condition | Complexity |
---|---|---|---|
`os << x` | reference to the type of `os` | With `os.fmtflags` set to `ios_base::dec|ios_base::left` and the fill character set to the space character, writes to `os` the textual representation of `x`'s current state. In the output, adjacent numbers are separated by one or more space characters. **Postconditions:** The `os.fmtflags` and fill character are unchanged. | \(O(\text{size of state})\) |

`is >> v` | reference to the type of `is` | With `is.fmtflags` set to `ios_base::dec`, sets `v`'s state as determined by reading its textual representation from `is`. If bad input is encountered, ensures that `v`'s state is unchanged by the operation and calls `is.setstate(ios_base::failbit)` (which may throw `ios_base::failure` (29.5.5.4)). If a textual representation written via `os << x` was subsequently read via `is >> v`, then `x == v` provided that there have been no intervening invocations of `x` or of `v`. **Preconditions:** `is` provides a textual representation that was previously written using an output stream whose imbued locale was the same as that of `is`, and whose type’s template specialization arguments `charT` and `traits` were respectively the same as those of `is`. **Postconditions:** The `is.fmtflags` are unchanged. | \(O(\text{size of state})\) |

---

5 E shall meet the *Cpp17CopyConstructible* (Table 29) and *Cpp17CopyAssignable* (Table 31) requirements. These operations shall each be of complexity no worse than \(O(\text{size of state})\).

26.6.2.5 Random number engine adaptor requirements

1 A random number engine adaptor (commonly shortened to *adaptor*) `a` of type `A` is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine `b` of type `B` adapted in this way is termed a base engine in this context. The expression `a.base()` shall be valid and shall return a const reference to `a`’s base engine.

The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

\[ A::A(); \]

**Effects:** The base engine is initialized as if by its default constructor.

\[ \text{bool operator==}(\text{const } A& a1, \text{const } A& a2); \]

**Returns:** `true` if `a1`’s base engine is equal to `a2`’s base engine. Otherwise returns `false`.  

---

§ 26.6.2.5 1134
A::A(result_type s);
5 Effects: The base engine is initialized with s.

template<class Sseq> A::A(Sseq& q);
6 Effects: The base engine is initialized with q.

void seed();
7 Effects: With b as the base engine, invokes b.seed().

void seed(result_type s);
8 Effects: With b as the base engine, invokes b.seed(s).

template<class Sseq> void seed(Sseq& q);
9 Effects: With b as the base engine, invokes b.seed(q).

A shall also meet the following additional requirements:

10.1 — The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.
10.2 — The state of A shall include the state of its base engine. The size of A’s state shall be no less than the size of the base engine.
10.3 — Copying A’s state (e.g., during copy construction or copy assignment) shall include copying the state of the base engine of A.
10.4 — The textual representation of A shall include the textual representation of its base engine.

26.6.2.6 Random number distribution requirements
[rand.req.dist]

A random number distribution (commonly shortened to distribution) d of type D is a function object returning values that are distributed according to an associated mathematical probability density function \( p(z) \) or according to an associated discrete probability function \( P(z_i) \). A distribution’s specification identifies its associated probability function \( p(z) \) or \( P(z_i) \).

An associated probability function is typically expressed using certain externally-supplied quantities known as the parameters of the distribution. Such distribution parameters are identified in this context by writing, for example, \( p(z | a, b) \) or \( P(z_i | a, b) \), to name specific parameters, or by writing, for example, \( p(z | \{ p \}) \) or \( P(z_i | \{ p \}) \), to denote a distribution’s parameters \( p \) taken as a whole.

A class D meets the requirements of a random number distribution if the expressions shown in Table 95 are valid and have the indicated semantics, and if D and its associated types also meet all other requirements of this subclause 26.6.2.6. In that Table and throughout this subclause,

1.1 — T is the type named by D’s associated result_type;
1.2 — P is the type named by D’s associated param_type;
1.3 — d is a value of D, and x and y are (possibly const) values of D;
1.4 — g1b and l1b are values of T respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by d’s operator(), as determined by the current values of d’s parameters;
1.5 — p is a (possibly const) value of P;
1.6 — g, g1, and g2 are lvalues of a type meeting the requirements of a uniform random bit generator (26.6.2.3);
1.7 — os is an lvalue of the type of some class template specialization basic_ostream<charT, traits>;
1.8 — is is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where \( \text{charT} \) and \( \text{traits} \) are constrained according to Clause 21 and Clause 29.

<td>reference to the type of os</td>
<td>Writes to os a textual representation for the parameters and the additional internal data of x. Postconditions: The os.fmtflags and fill character are unchanged.</td>
<td></td>
</tr>
</tbody>
</table>
Expression | Return type | Pre/post-condition | Complexity |
--- | --- | --- | --- |
`is >> d` | reference to the type of `is` | Restores from `is` the parameters and additional internal data of the lvalue `d`. If bad input is encountered, ensures that `d` is unchanged by the operation and calls `is.setstate(ios_base::failbit)` (which may throw `ios_base::failure (29.5.5.4)`). | `Preconditions`: `is` provides a textual representation that was previously written using an `os` whose imbued locale and whose type's template specialization arguments `charT` and `traits` were the same as those of `is`. `Postconditions`: The `is.fmtflags` are unchanged.|

4 D shall meet the Cpp17CopyConstructible (Table 29) and Cpp17CopyAssignable (Table 31) requirements.
5 The sequence of numbers produced by repeated invocations of `d(g)` shall be independent of any invocation of `os` `<< d` or of any `const` member function of `D` between any of the invocations `d(g)`.
6 If a textual representation is written using `os` `<< x` and that representation is restored into the same or a different object `y` of the same type using `is` `>> y`, repeated invocations of `y(g)` shall produce the same sequence of numbers as would repeated invocations of `x(g)`.
7 It is unspecified whether `D::param_type` is declared as a (nested) class or via a typedef. In this subclause 26.6, declarations of `D::param_type` are in the form of typedefs for convenience of exposition only.
8 P shall meet the Cpp17CopyConstructible (Table 29), Cpp17CopyAssignable (Table 31), and Cpp17EqualityComparable (Table 25) requirements.
9 For each of the constructors of `D` taking arguments corresponding to parameters of the distribution, `P` shall have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of `D` that return values corresponding to parameters of the distribution, `P` shall have a corresponding member function with the identical name, type, and semantics.
10 P shall have a declaration of the form `using distribution_type = D;`

### 26.6.3 Random number engine class templates

Each type instantiated from a class template specified in this subclause 26.6.3 meets the requirements of a random number engine (26.6.2.4) type.

Except where specified otherwise, the complexity of each function specified in this subclause 26.6.3 is constant.

Except where specified otherwise, no function described in this subclause 26.6.3 throws an exception.

Every function described in this subclause 26.6.3 that has a function parameter `q` of type `Sseq&` for a template type parameter named `Sseq` that is different from type `seed_seq` throws what and when the invocation of `q.generate` throws.

Descriptions are provided in this subclause 26.6.3 only for engine operations that are not described in 26.6.2.4 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

Each template specified in this subclause 26.6.3 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.
For every random number engine and for every random number engine adaptor X defined in this subclause (26.6.3) and in subclause 26.6.4:

(7.1) if the constructor

\[
\text{template<class Sseq> explicit X(Sseq& q);} \\
\]

is called with a type Sseq that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

(7.2) if the member function

\[
\text{template<class Sseq> void seed(Sseq& q);} \\
\]

is called with a type Sseq that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to \(X::\text{result\_type}\).

26.6.3.1 Class template \(\text{linear\_congruential\_engine}\) \([\text{rand.eng.long}]\)

A \(\text{linear\_congruential\_engine}\) random number engine produces unsigned integer random numbers. The state \(x_i\) of a \(\text{linear\_congruential\_engine}\) object \(x\) is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form \(TA(x_i) = (a \cdot x_i + c) \mod m\); the generation algorithm is \(GA(x_i) = x_i + 1\).

\[
\text{template<class UIntType, UIntType a, UIntType c, UIntType m> class linear\_congruential\_engine{ } } \\
\]

// types
using \text{result\_type} = \text{UIntType};

// engine characteristics
static constexpr \text{result\_type} multiplier = a;
static constexpr \text{result\_type} increment = c;
static constexpr \text{result\_type} modulus = m;
static constexpr \text{result\_type} min() { return c == 0u ? 1u: 0u; }
static constexpr \text{result\_type} max() { return m - 1u; }
static constexpr \text{result\_type} default\_seed = 1u;

// constructors and seeding functions
linear\_congruential\_engine() : linear\_congruential\_engine(default\_seed) {} \\
explicit linear\_congruential\_engine(result\_type s); \\
\text{template<class Sseq> explicit linear\_congruential\_engine(Sseq& q);} \\
void seed(result\_type s = default\_seed); \\
\text{template<class Sseq> void seed(Sseq& q);} \\

// generating functions
result\_type operator()();
void discard(unsigned long long z);

2 If the template parameter \(m\) is 0, the modulus \(m\) used throughout this subclause 26.6.3.1 is \text{numeric\_limits<result\_type>::max()} plus 1. [Note: \(m\) need not be representable as a value of type \text{result\_type}. — end note]

3 If the template parameter \(m\) is not 0, the following relations shall hold: \(a < m\) and \(c < m\).

4 The textual representation consists of the value of \(x_i\).

\[
\text{explicit linear\_congruential\_engine(result\_type s);} \\
\]

**Effects:** If \(c \mod m\) is 0 and \(s \mod m\) is 0, sets the engine’s state to 1, otherwise sets the engine’s state to \(s \mod m\).

\[
\text{template<class Sseq> explicit linear\_congruential\_engine(Sseq& q);} \\
\]

**Effects:** With \(k = \left\lceil \frac{\log_2 m}{32} \right\rceil\) and \(a\) an array (or equivalent) of length \(k + 3\), invokes \(q\).\text{generate(a + 0, a + k + 3)} and then computes \(S = \left(\sum_{j=0}^{k-1} a_{j+3} \cdot 2^{32j}\right) \mod m\). If \(c \mod m\) is 0 and \(S\) is 0, sets the engine’s state to 1, else sets the engine’s state to \(S\).
26.6.3.2 Class template mersenne_twister_engine

A mersenne_twister_engine random number engine[243] produces unsigned integer random numbers in the closed interval \([0, 2^w - 1]\). The state \(x_i\) of a mersenne_twister_engine object \(x\) is of size \(n\) and consists of a sequence \(X\) of \(n\) values of the type delivered by \(x\); all subscripts applied to \(X\) are to be taken modulo \(n\).

The transition algorithm employs a twisted generalized feedback shift register defined by shift values \(n\) and \(m\), a twist value \(r\), and a conditional xor-mask \(a\). To improve the uniformity of the result, the bits of the raw shift register are additionally tempered (i.e., scrambled) according to a bit-scrambling matrix defined by values \(u, d, s, b, t, c,\) and \(\ell\).

The state transition is performed as follows:

(2.1) Concatenate the upper \(w - r\) bits of \(X_{i-n}\) with the lower \(r\) bits of \(X_{i+1-n}\) to obtain an unsigned integer value \(Y\).

(2.2) With \(\alpha = a \cdot (Y \text{ bitand } 1)\), set \(X_i\) to \(X_i+m-n\ xor (Y \text{ rshift } 1) xor \alpha\).

The sequence \(X\) is initialized with the help of an initialization multiplier \(f\).

The generation algorithm determines the unsigned integer values \(z_1, z_2, z_3, z_4\) as follows, then delivers \(z_4\) as its result:

(3.1) Let \(z_1 = X_i \text{ xor } ((X_i \text{ rshift } u) \text{ bitand } d)\).

(3.2) Let \(z_2 = z_1 \text{ xor } ((z_1 \text{ lshift } w \text{ s}) \text{ bitand } b)\).

(3.3) Let \(z_3 = z_2 \text{ xor } ((z_2 \text{ lshift } w \text{ t}) \text{ bitand } c)\).

(3.4) Let \(z_4 = z_3 \text{ xor } (z_3 \text{ rshift } \ell)\).

```cpp
template<class UIntType, size_t w, size_t n, size_t m, size_t r, UIntType a, size_t u, UIntType d, size_t s, UIntType b, size_t t, UIntType c, size_t l, UIntType f>
class mersenne_twister_engine {
public:
  // types
  using result_type = UIntType;

  // engine characteristics
  static constexpr size_t word_size = w;
  static constexpr size_t state_size = n;
  static constexpr size_t shift_size = m;
  static constexpr size_t mask_bits = r;
  static constexpr UIntType xor_mask = a;
  static constexpr size_t tempering_u = u;
  static constexpr UIntType tempering_d = d;
  static constexpr size_t tempering_s = s;
  static constexpr UIntType tempering_b = b;
  static constexpr size_t tempering_t = t;
  static constexpr UIntType tempering_c = c;
  static constexpr size_t tempering_l = l;
  static constexpr UIntType initialization_multiplier = f;
  static constexpr result_type min() { return 0; }
  static constexpr result_type max() { return 2^w - 1; }
  static constexpr result_type default_seed = 5489u;

  // constructors and seeding functions
  mersenne_twister_engine() : mersenne_twister_engine(default_seed) {};
  explicit mersenne_twister_engine(result_type value);
  template<class Sseq> explicit mersenne_twister_engine(Sseq& q);
  void seed(result_type value = default_seed);
  template<class Sseq> void seed(Sseq& q);

  // generating functions
  result_type operator()();
  void discard(unsigned long long z);
```

---

243) The name of this engine refers, in part, to a property of its period: For properly-selected values of the parameters, the period is closely related to a large Mersenne prime number.
The generation algorithm is given by
\[ \text{subtract_with_carry_engine}(\text{result_type value}); \]

Effects: Sets \( X_{-n} \) to value \( 2^w \). Then, iteratively for \( i = 1 - n, \ldots, -1 \), sets \( X_i \) to
\[ f \cdot (X_{i-1} \oplus (X_{i-1} \text{ rshift} (w-2))) + i \text{ mod } n \ mod 2^w. \]

Complexity: \( O(n) \).

\[ \text{template<class Sseq> explicit mersenne_twister_engine(Sseq& q);} \]

Effects: With \( k = \lceil w/32 \rceil \) and \( a \) an array (or equivalent) of length \( n \cdot k \), invokes \( q \cdot \text{generate}(a + 0, a + n \cdot k) \) and then, iteratively for \( i = -n, \ldots, -1 \), sets \( X_i \) to
\[ \left( \sum_{j=0}^{k-1} a_{k(i+n)+j} \cdot 2^{32j} \right) \mod 2^w. \]
Finally, if the most significant \( w - r \) bits of \( X_{-n} \) are zero, and if each of the other resulting \( X_i \) is 0, changes \( X_{-n} \) to \( 2^{w-1} \).

26.6.3.3 Class template subtract_with_carry_engine

A subtract_with_carry_engine random number engine produces unsigned integer random numbers.

The state \( x_i \) of a subtract_with_carry_engine object \( x \) is of size \( O(r) \), and consists of a sequence \( X \) of \( r \) integer values \( 0 \leq X_i < m = 2^w \); all subscripts applied to \( X \) are to be taken modulo \( r \). The state \( x_i \) additionally consists of an integer \( c \) (known as the carry) whose value is either 0 or 1.

The state transition is performed as follows:

1. \( \text{Let } Y = X_{i-s} - X_{i-r} - c. \)
2. \( \text{Set } Y \text{ to } Y \text{ mod } m. \) Set \( c \) to 1 if \( Y < 0 \), otherwise set \( c \) to 0.

[Note: This algorithm corresponds to a modular linear function of the form \( TA(x_i) = (a \cdot x_i) \text{ mod } b \), where \( b \) is of the form \( m^r - m^l + 1 \) and \( a = b - (b-1)/m \). End note]

The generation algorithm is given by \( GA(x_i) = y \), where \( y \) is the value produced as a result of advancing the engine’s state as described above.

\[ \text{template<class UIntType, size_t w, size_t s, size_t r}> \text{class subtract_with_carry_engine } \{\]
\[ \text{public:} \]
\[ \text{// types} \]
\[ \text{using result_type = UIntType; } \]
\[ \text{// engine characteristics} \]
\[ \text{static constexpr size_t word_size = w; } \]
\[ \text{static constexpr size_t short_lag = s; } \]
\[ \text{static constexpr size_t long_lag = r; } \]
\[ \text{static constexpr result_type min() \{ return 0; \} } \]
\[ \text{static constexpr result_type max() \{ return m - 1; \} } \]
\[ \text{static constexpr result_type default_seed = 19780503u; } \]
\[ \text{// constructors and seeding functions} \]
\[ \text{subtract_with_carry_engine() : subtract_with_carry_engine(default_seed) \{\}} \]
\[ \text{explicit subtract_with_carry_engine(result_type value); } \]
\[ \text{template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);} \]
\[ \text{void seed(result_type value = default_seed);} \]
\[ \text{template<class Sseq> void seed(Sseq& q);} \]
\[ \} } \]
\[ \text{// generating functions} \]
\[ \text{result_type operator()(); } \]
\[ \text{void discard(unsigned long long z); } \]
\[ \}; \]

The following relations shall hold: \( 0u < s, s < r, 0 < w \), and \( w \leq \text{numeric_limits<UIntType>::digits.} \)
The textual representation consists of the values of $X_i, \ldots, X_{i-1}$, in that order, followed by $c$.

```cpp
explicit subtract_with_carry_engine(result_type value);
```

**Effects:** Sets the values of $X_i, \ldots, X_{i-1}$, in that order, as specified below. If $X_{i-1}$ is then 0, sets $c$ to 1; otherwise sets $c$ to 0.

To set the values $X_k$, first construct $e$, a linear_congruential_engine object, as if by the following definition:

```cpp
linear_congruential_engine
```

Then, to set each $X_k$, obtain new values $z_0, \ldots, z_{n-1}$ from $n = \lfloor w/32 \rfloor$ successive invocations of $e$ taken modulo $2^{32}$. Set $X_k$ to $\left(\sum_{j=0}^{n-1} z_j \cdot 2^{32j}\right) \mod m$.

**Complexity:** Exactly $n \cdot r$ invocations of $e$.

```cpp
template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
```

**Effects:** With $k = \lfloor w/32 \rfloor$ and $a$ an array (or equivalent) of length $r \cdot k$, invokes $q.generate(a+0, a+r \cdot k)$ and then, iteratively for $i = -r, \ldots, -1$, sets $X_i$ to $\left(\sum_{j=0}^{k-1} a_k(i+r) + j \cdot 2^{32j}\right) \mod m$. If $X_{i-1}$ is then 0, sets $c$ to 1; otherwise sets $c$ to 0.

### 26.6.4 Random number engine adaptor class templates

#### 26.6.4.1 In general

Each type instantiated from a class template specified in this subclause 26.6.4 meets the requirements of a random number engine adaptor (26.6.2.5) type.

Except where specified otherwise, the complexity of each function specified in this subclause 26.6.4 is constant.

Except where specified otherwise, no function described in this subclause 26.6.4 throws an exception.

Every function described in this subclause 26.6.4 that has a function parameter $q$ of type Sseq& for a template type parameter named Sseq that is different from type seed_seq throws what and when the invocation of $q.generate$ throws.

Descriptions are provided in this subclause 26.6.4 only for adaptor operations that are not described in subclause 26.6.2.5 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

Each template specified in this subclause 26.6.4 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

#### 26.6.4.2 Class template discard_block_engine

A discard_block_engine random number engine adaptor produces random numbers selected from those produced by some base engine $e$. The state $x_i$ of a `discard_block_engine` engine adaptor object $x$ consists of the state $e_i$ of its base engine $e$ and an additional integer $n$. The size of the state is the size of $e$’s state plus 1.

The transition algorithm discards all but $r > 0$ values from each block of $p \geq r$ values delivered by $e$. The state transition is performed as follows: If $n \geq r$, advance the state of $e$ from $e_i$ to $e_{i+p-r}$ and set $n$ to 0. In any case, then increment $n$ and advance $e$’s then-current state $e_j$ to $e_{j+1}$.

The generation algorithm yields the value returned by the last invocation of $e()$ while advancing $e$’s state as described above.

```cpp
template<class Engine, size_t p, size_t r>
class discard_block_engine {
public:

  // types
  using result_type = typename Engine::result_type;

  // engine characteristics
  static constexpr size_t block_size = p;
  static constexpr size_t used_block = r;
  static constexpr result_type min() { return Engine::min(); }
```
The following relations shall hold: $0 < r$ and $r \leq p$.

The textual representation consists of the textual representation of $e$ followed by the value of $n$.

In addition to its behavior pursuant to subclause 26.6.2.5, each constructor that is not a copy constructor sets $n$ to 0.

26.6.4.3 Class template independent_bits_engine

An independent_bits_engine random number engine adaptor combines random numbers that are produced by some base engine $e$, so as to produce random numbers with a specified number of bits $w$. The state $x_i$ of an independent_bits_engine engine adaptor object $x$ consists of the state $e_i$ of its base engine $e$; the size of the state is the size of $e$’s state.

The transition and generation algorithms are described in terms of the following integral constants:

1. Let $R = e.\max() - e.\min() + 1$ and $m = \lceil \log_2 R \rceil$.
2. With $u$ as determined below, let $w_0 = \lfloor w/n \rfloor$, $n_0 = n - w \bmod n$, $y_0 = 2^{w_0} \lfloor R/2^{w_0} \rfloor$, and $y_1 = 2^{w_0+1} \lfloor R/2^{w_0+1} \rfloor$.

[Note: The relation $w = n_0 w_0 + (n - n_0)(w_0 + 1)$ always holds. — end note]

The transition algorithm is carried out by invoking $e()$ as often as needed to obtain $n_0$ values less than $y_0 + e.\min()$ and $n - n_0$ values less than $y_1 + e.\min()$.

The generation algorithm uses the values produced while advancing the state as described above to yield a quantity $S$ obtained as if by the following algorithm:

```cpp
S = 0;
for (k = 0; k != n0; k++) {
    do u = e() - e.\min(); while (u >= y0);
    S = 2^{w_0} \cdot S + u \bmod 2^{w_0};
}
for (k = n0; k != n; k++) {
    do u = e() - e.\min(); while (u >= y1);
    S = 2^{w_0+1} \cdot S + u \bmod 2^{w_0+1};
}
```

template<class Engine, size_t w, class UIntType>
class independent_bits_engine {
  public:
    // types
    using result_type = UIntType;
};
// engine characteristics
static constexpr result_type min() { return 0; }
static constexpr result_type max() { return 2^w - 1; }

// constructors and seeding functions
independent_bits_engine();
extPLICIT independent_bits_engine(const Engine& e);
extPLICIT independent_bits_engine(Engine&& e);
extPLICIT independent_bits_engine(result_type s);
template<class Sseq> explicit independent_bits_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; };

private:
  Engine e; // exposition only

The following relations shall hold: 0 < w and w <= numeric_limits<result_type>::digits.
The textual representation consists of the textual representation of e.

26.6.4.4 Class template shuffle_order_engine

A shuffle_order_engine random number engine adaptor produces the same random numbers that are produced
by some base engine e, but delivers them in a different sequence. The state x_i of a shuffle_order_engine engine
 adaptor object x consists of the state e_i of its base engine e, an additional value Y_i of the type delivered by e, and an
additional sequence V_i of k values also of the type delivered by e. The size of the state is the size of e_i’s state plus
k + 1.

The transition algorithm permutes the values produced by e. The state transition is performed as follows:

(2.1) Calculate an integer

\( j = \left\lfloor \frac{k(Y - e_{\text{min}})}{e_{\text{max}} - e_{\text{min}} + 1} \right\rfloor. \)

(2.2) Set Y to V_j and then set V_j to e().

The generation algorithm yields the last value of Y produced while advancing e_i’s state as described above.

template<class Engine, size_t k>
class shuffle_order_engine {
public:
  // types
  using result_type = typename Engine::result_type;

  // engine characteristics
  static constexpr size_t table_size = k;
  static constexpr result_type min() { return Engine::min(); }
  static constexpr result_type max() { return Engine::max(); }

  // constructors and seeding functions
  shuffle_order_engine();
extPLICIT shuffle_order_engine(const Engine& e);
extPLICIT shuffle_order_engine(Engine&& e);
extPLICIT shuffle_order_engine(result_type s);
template<class Sseq> explicit shuffle_order_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);
// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; };

private:
Engine e;       // exposition only
result_type V[k];  // exposition only
result_type Y;   // exposition only

The following relation shall hold: $0 < k$.
The textual representation consists of the textual representation of $e$, followed by the $k$ values of $V$, followed by the value of $Y$.
In addition to its behavior pursuant to subclause 26.6.2.5, each constructor that is not a copy constructor initializes $V[0], \ldots, V[k-1]$ and $Y$, in that order, with values returned by successive invocations of $e()$.

### 26.6.5 Engines and engine adaptors with predefined parameters

using minstd_rand0 =
linear_congruential_engine<uint_fast32_t, 16'807, 0, 2'147'483'647>;

*Required behavior:* The 10000th consecutive invocation of a default-constructed object of type minstd_rand0 produces the value 1043618065.

using minstd_rand =
linear_congruential_engine<uint_fast32_t, 48'271, 0, 2'147'483'647>;

*Required behavior:* The 10000th consecutive invocation of a default-constructed object of type minstd_rand produces the value 3992658537.

using mt19937 =
mersenne_twister_engine<uint_fast32_t, 32, 624, 397, 31,
0x9908b0df, 11, 0xffffffff, 7, 0x9d2c5680, 15, 0xefc60000, 18, 1'812'433'253>;

*Required behavior:* The 10000th consecutive invocation of a default-constructed object of type mt19937 produces the value 4123659995.

using mt19937_64 =
mersenne_twister_engine<uint_fast64_t, 64, 312, 156, 31,
0xb5026f5a'a966'19e9, 29, 0x5555'5555'5555'5555, 17,
0x71d6'7fff'eda6'0000, 37, 0xffffffff, 43, 6'364'136'223'846'793'005>;

*Required behavior:* The 10000th consecutive invocation of a default-constructed object of type mt19937_64 produces the value 9981545732273789042.

using ranlux24_base =
subtract_with_carry_engine<uint_fast32_t, 24, 10, 24>;

*Required behavior:* The 10000th consecutive invocation of a default-constructed object of type ranlux24_base produces the value 7937952.

using ranlux48_base =
subtract_with_carry_engine<uint_fast64_t, 48, 5, 12>;

*Required behavior:* The 10000th consecutive invocation of a default-constructed object of type ranlux48_base produces the value 61839128582725.

using ranlux24 = discard_block_engine<ranlux24_base, 223, 23>;

*Required behavior:* The 10000th consecutive invocation of a default-constructed object of type ranlux24 produces the value 9901578.
using ranlux48 = discard_block_engine<ranlux48_base, 389, 11>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48 produces the value 249142670248501.

using knuth_b = shuffle_order_engine<minstd_rand0, 256>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type knuth_b produces the value 1112339016.

using default_random_engine = implementation-defined;

Remarks: The choice of engine type named by this typedef is implementation-defined. [Note: The implementation may select this type on the basis of performance, size, quality, or any combination of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexpert, and/or lightweight use. Because different implementations may select different underlying engine types, code that uses this typedef need not generate identical sequences across implementations. — end note]

26.6.6 Class random_device

A random_device uniform random bit generator produces nondeterministic random numbers.

If implementation limitations prevent generating nondeterministic random numbers, the implementation may employ a random number engine.

class random_device {
    public:
        // types
        using result_type = unsigned int;

        // generator characteristics
        static constexpr result_type min() { return numeric_limits<result_type>::min(); }
        static constexpr result_type max() { return numeric_limits<result_type>::max(); }

        // constructors
        random_device() : random_device(implementation-defined) {} 
        explicit random_device(const string& token);

        // generating functions
        result_type operator()();

        // property functions
        double entropy() const noexcept;

        // no copy functions
        random_device(const random_device&) = delete;
        void operator=(const random_device&) = delete;
    };

    explicit random_device(const string& token);

    // The parameter is intended to allow an implementation to differentiate between different sources of randomness.

    // If a device has n states whose respective probabilities are P_0, ..., P_{n-1}, the device entropy S is defined as
    // S = - \sum_{i=0}^{n-1} P_i \cdot \log P_i.

    double entropy() const noexcept;

    Returns: If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate for the random numbers returned by operator(), in the range min() to log_2(max() + 1).

    result_type operator()();

    Returns: A nondeterministic random value, uniformly distributed between min() and max() (inclusive). It is implementation-defined how these values are generated.

§ 26.6.6
Throws: A value of an implementation-defined type derived from exception if a random number could not be obtained.

26.6.7 Utilities

26.6.7.1 Class seed_seq

```cpp
class seed_seq {
public:
    // types
    using result_type = uint_least32_t;

    // constructors
    seed_seq();
    template<class T>
    seed_seq(initializer_list<T> il);
    template<class InputIterator>
    seed_seq(InputIterator begin, InputIterator end);

    // generating functions
    template<class RandomAccessIterator>
    void generate(RandomAccessIterator begin, RandomAccessIterator end);

    // property functions
    size_t size() const noexcept;
    template<class OutputIterator>
    void param(OutputIterator dest) const;

    // no copy functions
    seed_seq(const seed_seq&) = delete;
    void operator=(const seed_seq&) = delete;

private:
    vector<result_type> v; // exposition only
};
```

1 Postconditions: v.empty() is true.

2 Throws: Nothing.

```cpp
template<class T>
seed_seq(initializer_list<T> il);
```

3 Mandates: T is an integer type.

4 Effects: Same as seed_seq(il.begin(), il.end()).

```cpp
template<class InputIterator>
seed_seq(InputIterator begin, InputIterator end);
```

5 Mandates: iterator_traits<InputIterator>::value_type is an integer type.

6 Preconditions: InputIterator meets the Cpp17InputIterator requirements (23.3.5.2).

7 Effects: Initializes v by the following algorithm:

```cpp
for (InputIterator s = begin; s != end; ++s)
    v.push_back((s)mod2^32);
```

```cpp
template<class RandomAccessIterator>
void generate(RandomAccessIterator begin, RandomAccessIterator end);
```

8 Mandates: iterator_traits<RandomAccessIterator>::value_type is an unsigned integer type capable of accommodating 32-bit quantities.

9 Preconditions: RandomAccessIterator meets the Cpp17RandomAccessIterator requirements (23.3.5.6) and the requirements of a mutable iterator.

10 Effects: Does nothing if begin == end. Otherwise, with s = v.size() and n = end - begin, fills the supplied range [begin, end) according to the following algorithm in which each operation is to be carried
out modulo $2^{32}$, each indexing operator applied to begin is to be taken modulo $n$, and $T(x)$ is defined as $x\text{xor}(x\text{rshift}27)$:

- By way of initialization, set each element of the range to the value 0x8b8b8b8b. Additionally, for use in subsequent steps, let $p = (n - t)/2$ and let $q = p + t$, where $t = (n \geq 623) \cdot 11 : (n \geq 68) \cdot 7 : (n \geq 39) ? 5 : (n \geq 7) ? 3 : (n - 1)/2$;

- With $m$ as the larger of $s + 1$ and $n$, transform the elements of the range: iteratively for $k = 0, \ldots, m - 1$, calculate values
  \[ r_1 = 1664525 \cdot T(\text{begin}[k] \text{xor} \text{begin}[k + p] \text{xor} \text{begin}[k - 1]) \]
  \[ r_2 = r_1 + \begin{cases} 
    s, & k = 0 \\
    k \bmod n + v[k - 1], & 0 < k < s \\
    k \bmod n, & s < k 
  \end{cases} \]

and, in order, increment $\text{begin}[k + p]$ by $r_1$, increment $\text{begin}[k + q]$ by $r_2$, and set $\text{begin}[k]$ to $r_2$.

- Transform the elements of the range again, beginning where the previous step ended: iteratively for $k = m, \ldots, m + n - 1$, calculate values
  \[ r_3 = 1566083941 \cdot T(\text{begin}[k] + \text{begin}[k + p] + \text{begin}[k - 1]) \]
  \[ r_4 = r_3 - (k \bmod n) \]

and, in order, update $\text{begin}[k + p]$ by xoring it with $r_3$, update $\text{begin}[k + q]$ by xoring it with $r_4$, and set $\text{begin}[k]$ to $r_4$.

**Throws**: What and when RandomAccessIterator operations of begin and end throw.

```cpp
size_t size() const noexcept;
```

**Returns**: The number of 32-bit units that would be returned by a call to param().

**Complexity**: Constant time.

```cpp
template<class OutputIterator>
void param(OutputIterator dest) const;
```

**Mandates**: Values of type result_type are writable (23.3.1) to dest.

**Preconditions**: OutputIterator meets the Cpp17OutputIterator requirements (23.3.5.3).

**Effects**: Copies the sequence of prepared 32-bit units to the given destination, as if by executing the following statement:

```cpp
copy(v.begin(), v.end(), dest);
```

**Throws**: What and when OutputIterator operations of dest throw.

### 26.6.7.2 Function template generate_canonical

```cpp
template<class RealType, size_t bits, class URBG>
RealType generate_canonical(URBG& g);
```

**Complexity**: Exactly $k = \max(1, \lceil b/\log_2 R \rceil)$ invocations of $g$, where $b$ is the lesser of numeric_limits<RealType>::digits and bits, and $R$ is the value of $g\cdot\max() - g\cdot\min() + 1$.

**Effects**: Invokes $g()$ $k$ times to obtain values $g_0, \ldots, g_{k - 1}$, respectively. Calculates a quantity

\[ S = \sum_{i=0}^{k-1}(g_i - g\cdot\min()) \cdot R^i \]

using arithmetic of type RealType.

**Returns**: $S/R^k$. [Note: $0 \leq S/R^k < 1$. — end note]

**Throws**: What and when $g$ throws.

[Note: If the values $g_i$ produced by $g$ are uniformly distributed, the instantiation’s results are distributed as uniformly as possible. Obtaining a value in this way can be a useful step in the process of transforming a value generated by a uniform random bit generator into a value that can be delivered by a random number distribution. — end note]

---

\[b\] is introduced to avoid any attempt to produce more bits of randomness than can be held in RealType.
26.6.8 Random number distribution class templates [rand.dist]

26.6.8.1 In general [rand.dist.general]
1 Each type instantiated from a class template specified in this subclause 26.6.8 meets the requirements of a random number distribution (26.6.2.6) type.
2 Descriptions are provided in this subclause 26.6.8 only for distribution operations that are not described in 26.6.2.6 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.
3 The algorithms for producing each of the specified distributions are implementation-defined.
4 The value of each probability density function \( p(z) \) and of each discrete probability function \( P(z_i) \) specified in this subclause is 0 everywhere outside its stated domain.

26.6.8.2 Uniform distributions [rand.dist.uni]

26.6.8.2.1 Class template uniform_int_distribution [rand.dist.uni.int]
1 A uniform_int_distribution random number distribution produces random integers \( i, a \leq i \leq b \), distributed according to the constant discrete probability function

\[
P(i \mid a, b) = \frac{1}{b - a + 1}.
\]

```cpp
template<class IntType = int>
class uniform_int_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    uniform_int_distribution() : uniform_int_distribution(0) {}       
    explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());
    explicit uniform_int_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

2 Preconditions: \( a \leq b \).
3 Remarks: \( a \) and \( b \) correspond to the respective parameters of the distribution.
4 Returns: The value of the \( a \) parameter with which the object was constructed.
5 Returns: The value of the \( b \) parameter with which the object was constructed.
26.6.8.2.2 Class template uniform_real_distribution

A uniform_real_distribution random number distribution produces random numbers \(x, a \leq x < b\), distributed according to the constant probability density function

\[ p(x | a, b) = \frac{1}{(b - a)} . \]

[Note: This implies that \(p(x | a, b)\) is undefined when \(a == b\). — end note]

```cpp
template<class RealType = double>
class uniform_real_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructors and reset functions
    uniform_real_distribution() : uniform_real_distribution(0.0) {}
    explicit uniform_real_distribution(RealType a, RealType b = 1.0);
    explicit uniform_real_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    const param_type& param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

26.6.8.3 Bernoulli distributions

26.6.8.3.1 Class bernoulli_distribution

A bernoulli_distribution random number distribution produces bool values \(b\) distributed according to the discrete probability function

\[ P(b | p) = \begin{cases} p & \text{if } b = \text{true}, \\ 1 - p & \text{if } b = \text{false}. \end{cases} \]

```cpp
class bernoulli_distribution {
public:
    // types
    using result_type = bool;
    using param_type = unspecified;
```
Bernoulli Distribution

```cpp
bernoulli_distribution() : bernoulli_distribution(0.5) {}
explicit bernoulli_distribution(double p);
explicit bernoulli_distribution(const param_type& parm);
void reset();
```

### Generating Functions

```cpp
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);
```

### Property Functions

```cpp
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
```

#### Preconditions:

\[ 0 \leq p \leq 1. \]

#### Remarks:

\( p \) corresponds to the parameter of the distribution.

#### Returns:

The value of the \( p \) parameter with which the object was constructed.

---

**26.6.8.3.2 Class template binomial_distribution**

A binomial_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i | t, p) = \binom{t}{i} \cdot p^i \cdot (1 - p)^{t-i}.
\]

```cpp
template<class IntType = int>
class binomial_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    binomial_distribution() : binomial_distribution(1) {}
    explicit binomial_distribution(IntType t, double p = 0.5);
    explicit binomial_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    IntType t() const;
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```
explicit binomial_distribution(IntType t, double p = 0.5);

Preconditions: $0 \leq p \leq 1$ and $0 \leq t$.

Remarks: $t$ and $p$ correspond to the respective parameters of the distribution.

IntType t() const;

Returns: The value of the $t$ parameter with which the object was constructed.

double p() const;

Returns: The value of the $p$ parameter with which the object was constructed.

26.6.8.3.3 Class template geometric_distribution

A geometric_distribution random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid p) = p \cdot (1 - p)^i.$$ 

template<class IntType = int>
class geometric_distribution {
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;

        // constructors and reset functions
        geometric_distribution() : geometric_distribution(0.5) {};
        explicit geometric_distribution(double p);
        explicit geometric_distribution(const param_type& parm);
        void reset();

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        double p() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;
    };

    explicit geometric_distribution(double p);

    Preconditions: $0 < p < 1$.

    Remarks: $p$ corresponds to the parameter of the distribution.

double p() const;

Returns: The value of the $p$ parameter with which the object was constructed.

26.6.8.3.4 Class template negative_binomial_distribution

A negative_binomial_distribution random number distribution produces random integers $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid k, p) = \binom{k + i - 1}{i} \cdot p^k \cdot (1 - p)^i.$$ 

[Note: This implies that $P(i \mid k, p)$ is undefined when $p = 1$. — end note]
template<class IntType = int>
class negative_binomial_distribution {
public:
  // types
  using result_type = IntType;
  using param_type = unspecified;

  // constructor and reset functions
  negative_binomial_distribution() : negative_binomial_distribution(1) {}  
  explicit negative_binomial_distribution(IntType k, double p = 0.5);  
  explicit negative_binomial_distribution(const param_type& parm);  
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);  
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

  // property functions
  IntType k() const;
  double p() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;

  explicit negative_binomial_distribution(IntType k, double p = 0.5);

  2 Preconditions: 0 < p ≤ 1 and 0 < k.
  Remarks: k and p correspond to the respective parameters of the distribution.

  IntType k() const;
  Returns: The value of the k parameter with which the object was constructed.

  double p() const;
  Returns: The value of the p parameter with which the object was constructed.

26.6.8.4 Poisson distributions

26.6.8.4.1 Class template poisson_distribution

A poisson_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i | \mu) = \frac{e^{-\mu} \mu^i}{i!}.
\]

The distribution parameter \( \mu \) is also known as this distribution’s mean.

template<class IntType = int>
class poisson_distribution {
public:
  // types
  using result_type = IntType;
  using param_type = unspecified;

  // constructors and reset functions
  poisson_distribution() : poisson_distribution(1.0) {}  
  explicit poisson_distribution(double mean);
  explicit poisson_distribution(const param_type& parm);
  void reset();

§ 26.6.8.4.1
// generating functions
template<class URBG>
result_type operator()(URBG& g);

// property functions
real_type mean() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// explicit poisson_distribution(double mean);

Preconditions: 0 < mean.
Remarks: mean corresponds to the parameter of the distribution.

double mean() const;

Returns: The value of the mean parameter with which the object was constructed.

§ 26.6.8.4.2  Class template exponential_distribution

An exponential_distribution random number distribution produces random numbers $x > 0$ distributed according to the probability density function $p(x \mid \lambda) = \lambda e^{-\lambda x}$. 

template<class RealType = double>
class exponential_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructors and reset functions
    exponential_distribution(); exponential_distribution(1.0) {}
    exponential_distribution<RealType lambda);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    
    // property functions
    RealType lambda() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;

    explicit exponential_distribution<RealType lambda);

    Preconditions: 0 < lambda.
    Remarks: lambda corresponds to the parameter of the distribution.

    RealType lambda() const;
    Returns: The value of the lambda parameter with which the object was constructed.

26.6.8.4.3 Class template gamma_distribution

A `gamma_distribution` random number distribution produces random numbers $x > 0$ distributed according to the probability density function

\[
p(x \mid \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \cdot \Gamma(\alpha)} \cdot x^{\alpha-1}.
\]

template<class RealType = double>

```
class gamma_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructors and reset functions
    gamma_distribution() : gamma_distribution(1.0) {};
    explicit gamma_distribution(RealType alpha, RealType beta = 1.0);
    explicit gamma_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType alpha() const;
    RealType beta() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

explicit gamma_distribution(RealType alpha, RealType beta = 1.0);

2 Preconditions: $0 < \alpha$ and $0 < \beta$.

3 Remarks: $\alpha$ and $\beta$ correspond to the parameters of the distribution.

RealType alpha() const;

4 Returns: The value of the $\alpha$ parameter with which the object was constructed.

RealType beta() const;

5 Returns: The value of the $\beta$ parameter with which the object was constructed.

26.6.8.4.4 Class template weibull_distribution

A `weibull_distribution` random number distribution produces random numbers $x \geq 0$ distributed according to the probability density function

\[
p(x \mid a, b) = \frac{a}{b} \cdot \left(\frac{x}{b}\right)^{a-1} \cdot \exp\left(-\left(\frac{x}{b}\right)^a\right).
\]

template<class RealType = double>

```
class weibull_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    weibull_distribution() : weibull_distribution(1.0) {};
    explicit weibull_distribution(RealType a, RealType b = 1.0);
    explicit weibull_distribution(const param_type& parm);
    void reset();
};
```
```cpp
// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType a() const;
RealType b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

};

explicit weibull_distribution(RealType a, RealType b = 1.0);

2
Preconditions: 0 < a and 0 < b.

3
Remarks: a and b correspond to the respective parameters of the distribution.

RealType a() const;

4
Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

5
Returns: The value of the b parameter with which the object was constructed.

26.6.8.4.5 Class template extreme_value_distribution

1 An extreme_value_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid a, b) = \frac{1}{b} \exp \left(\frac{a - x}{b} - \exp \left(\frac{a - x}{b}\right)\right).
\]

template<class RealType = double>
class extreme_value_distribution {
public:

// types
using result_type = RealType;
using param_type = unspecified;

// constructor and reset functions
extreme_value_distribution() : extreme_value_distribution(0.0) {}
explicit extreme_value_distribution(RealType a, RealType b = 1.0);
explicit extreme_value_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType a() const;
RealType b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

};

247) The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.

§ 26.6.8.4.5

1155
explicit extreme_value_distribution(RealType a, RealType b = 1.0);

Preconditions: $0 < b$.

Remarks: $a$ and $b$ correspond to the respective parameters of the distribution.

RealType a() const;

Returns: The value of the $a$ parameter with which the object was constructed.

RealType b() const;

Returns: The value of the $b$ parameter with which the object was constructed.

### 26.6.8.5 Normal distributions

#### 26.6.8.5.1 Class template normal_distribution

A normal_distribution random number distribution produces random numbers $x$ distributed according to the probability density function

$$p(x | \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right).$$

The distribution parameters $\mu$ and $\sigma$ are also known as this distribution’s mean and standard deviation.

```cpp
template<class RealType = double>
class normal_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

  // constructors and reset functions
  normal_distribution() : normal_distribution(0.0) {} explicit normal_distribution(RealType mean, RealType stddev = 1.0);
  explicit normal_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

  // property functions
  RealType mean() const;
  RealType stddev() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};
```

explicit normal_distribution(RealType mean, RealType stddev = 1.0);

Preconditions: $0 < \text{stddev}$.

Remarks: mean and stddev correspond to the respective parameters of the distribution.

RealType mean() const;

Returns: The value of the mean parameter with which the object was constructed.

RealType stddev() const;

Returns: The value of the stddev parameter with which the object was constructed.
26.6.8.5.2 Class template lognormal_distribution

A lognormal_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x \mid m, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{(\ln x - m)^2}{2s^2}\right).
\]

\[
\text{template<class RealType = double>}
\]

\[
\text{class lognormal_distribution }\{\text{\}}
\]

\[
\text{public:}
\]

\[
\text{using result_type = RealType;}
\]

\[
\text{using param_type = unspecified;}
\]

\[
\text{// constructor and reset functions}
\]

\[
\text{lognormal_distribution()} : \text{lognormal_distribution}(0.0) {}\}
\]

\[
\text{explicit lognormal_distribution(RealType m, RealType s = 1.0);}\}
\]

\[
\text{explicit lognormal_distribution(const param_type& parm);}\}
\]

\[
\text{void reset();}
\]

\[
\text{// generating functions}
\]

\[
\text{template<class URBG>}
\]

\[
\text{result_type operator()(URBG& g);}\}
\]

\[
\text{template<class URBG>}
\]

\[
\text{result_type operator()(URBG& g, const param_type& parm);}\}
\]

\[
\text{// property functions}
\]

\[
\text{RealType m() const;}\]

\[
\text{RealType s() const;}\]

\[
\text{param_type param() const;}\]

\[
\text{void param(const param_type& parm);}\}
\]

\[
\text{result_type min() const;}\]

\[
\text{result_type max() const;}\}
\]

\[
\text{explicit lognormal_distribution(RealType m, RealType s = 1.0);}\]

\[
\text{Preconditions: 0 < s.}
\]

\[
\text{Remarks: m and s correspond to the respective parameters of the distribution.}
\]

\[
\text{RealType m() const;}\]

\[
\text{Returns: The value of the m parameter with which the object was constructed.}
\]

\[
\text{RealType s() const;}\]

\[
\text{Returns: The value of the s parameter with which the object was constructed.}
\]

26.6.8.5.3 Class template chi_squared_distribution

A chi_squared_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x \mid n) = \frac{x^{(n/2) - 1} \cdot e^{-x/2}}{\Gamma(n/2) \cdot 2^{n/2}}.
\]

\[
\text{template<class RealType = double>}
\]

\[
\text{class chi_squared_distribution }\{\text{\}}
\]

\[
\text{public:}
\]

\[
\text{using result_type = RealType;}
\]

\[
\text{using param_type = unspecified;}
\]

\[
\text{// constructor and reset functions}
\]

\[
\text{chi_squared_distribution()} : \text{chi_squared_distribution}(1.0) {}\}
\]

\[
\text{explicit chi_squared_distribution(RealType n);}\]

\[
\text{§ 26.6.8.5.3}
\]
explicit chi_squared_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType n() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit chi_squared_distribution(RealType n);

2 Preconditions: 0 < n.
3 Remarks: n corresponds to the parameter of the distribution.

RealType n() const;
4 Returns: The value of the n parameter with which the object was constructed.

26.6.8.5.4 Class template cauchy_distribution
[rand.dist.norm.cauchy]
1 A cauchy_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x | a, b) = \frac{1}{\pi b \left(1 + \left(\frac{x - a}{b}\right)^2\right)}^{-1}.
\]

template<class RealType = double>
class cauchy_distribution {
public:
// types
using result_type = RealType;
using param_type = unspecified;

// constructor and reset functions
cauchy_distribution() : cauchy_distribution(0.0) {}
explicit cauchy_distribution(RealType a, RealType b = 1.0);
explicit cauchy_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType a() const;
RealType b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit cauchy_distribution(RealType a, RealType b = 1.0);

2 Preconditions: 0 < b.
3 Remarks: a and b correspond to the respective parameters of the distribution.
RealType a() const;
4 Returns: The value of the a parameter with which the object was constructed.

RealType b() const;
5 Returns: The value of the b parameter with which the object was constructed.

26.6.8.5.5 Class template fisher_f_distribution

A fisher_f_distribution random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x \mid m, n) = \frac{\Gamma((m + n)/2)}{\Gamma(m/2) \Gamma(n/2)} \cdot \left(\frac{m}{n}\right)^{m/2} \cdot x^{(m/2)-1} \cdot \left(1 + \frac{mx}{n}\right)^{-(m+n)/2}.
\]

```cpp
template<class RealType = double>
class fisher_f_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    fisher_f_distribution() : fisher_f_distribution(1.0) {}
    explicit fisher_f_distribution(RealType m, RealType n = 1.0);
    explicit fisher_f_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType m() const;
    RealType n() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

class fisher_f_distribution(RealType m, RealType n = 1);

Preconditions: \( 0 < m \) and \( 0 < n \).
Remarks: \( m \) and \( n \) correspond to the respective parameters of the distribution.

RealType m() const;
4 Returns: The value of the m parameter with which the object was constructed.

RealType n() const;
5 Returns: The value of the n parameter with which the object was constructed.

26.6.8.5.6 Class template student_t_distribution

A student_t_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid n) = \frac{1}{\sqrt{n\pi}} \cdot \frac{\Gamma((n + 1)/2)}{\Gamma(n/2)} \cdot \left(1 + \frac{x^2}{n}\right)^{-(n+1)/2}.
\]
template<class RealType = double>
class student_t_distribution {
public:

  using result_type = RealType;

explicit student_t_distribution(RealType n);

2  Preconditions: 0 < n.

3  Remarks: n corresponds to the parameter of the distribution.

RealType n() const;

4  Returns: The value of the n parameter with which the object was constructed.

26.6.8.6 Sampling distributions [rand.dist.samp]

26.6.8.6.1 Class template discrete_distribution [rand.dist.samp.discrete]

1  A discrete_distribution random number distribution produces random integers \( i, 0 \leq i < n \), distributed according to the discrete probability function

\[
P(i | p_0, \ldots, p_{n-1}) = p_i.
\]

2  Unless specified otherwise, the distribution parameters are calculated as: \( p_k = w_k / S \) for \( k = 0, \ldots, n - 1 \), in which the values \( w_k \), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \( 0 < S = w_0 + \cdots + w_{n-1} \).

template<class IntType = int>
class discrete_distribution {
public:

  using result_type = IntType;
  using param_type = unspecified;

  discrete_distribution();
  template<class InputIterator>
  discrete_distribution(InputIterator firstW, InputIterator lastW);
  discrete_distribution(initializer_list<double> wl);
  template<class UnaryOperation>
  discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
  explicit discrete_distribution(const param_type& parm);
  void reset();
};
// generating functions
template<class URBG>
result_type operator()(URBG& g);

template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
vector<double> probabilities() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

};

discrete_distribution();

Effects: Constructs a discrete_distribution object with \( n = 1 \) and \( p_0 = 1 \). [Note: Such an object will always deliver the value 0. — end note]

template<class InputIterator>
discrete_distribution(InputIterator firstW, InputIterator lastW);

Mandates: \( \text{is_convertible_v<iterator_traits<InputIterator>::value_type, double> is true.} \)

Preconditions: InputIterator meets the Cpp17InputIterator requirements (23.3.5.2). If \( \text{firstW == lastW} \), let \( n = 1 \) and \( w_0 = 1 \). Otherwise, \( \text{[firstW,lastW]} \) forms a sequence \( w \) of length \( n > 0 \).

Effects: Constructs a discrete_distribution object with probabilities given by the formula above.

discrete_distribution(initializer_list<double> wl);

Effects: Same as discrete_distribution(wl.begin(), wl.end()).

template<class UnaryOperation>
discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);

Mandates: \( \text{is_invocable_r_v<double, UnaryOperation&, double> is true.} \)

Preconditions: If \( nw = 0 \), let \( n = 1 \), otherwise let \( n = nw \). The relation \( 0 < \delta = (\text{xmax} - \text{xmin})/n \) holds.

Effects: Constructs a discrete_distribution object with probabilities given by the formula above, using the following values: If \( nw = 0 \), let \( w_0 = 1 \). Otherwise, let \( w_k = fw(\text{xmin} + k \cdot \delta + \delta/2) \) for \( k = 0, \ldots, n-1 \).

Complexity: The number of invocations of \( fw \) does not exceed \( n \).

vector<double> probabilities() const;

Returns: A vector<double> whose size member returns \( n \) and whose operator[] member returns \( p_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n - 1 \).

26.6.8.6.2 Class template piecewise_constant_distribution

A piecewise_constant_distribution random number distribution produces random numbers \( x, b_0 \leq x < b_n \), uniformly distributed over each subinterval \( [b_i, b_{i+1}) \) according to the probability density function

\[
p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_{n-1}) = \rho_i, \text{ for } b_i \leq x < b_{i+1}.
\]

The \( n + 1 \) distribution parameters \( b_i \), also known as this distribution’s interval boundaries, shall satisfy the relation \( b_i < b_{i+1} \) for \( i = 0, \ldots, n - 1 \). Unless specified otherwise, the remaining \( n \) distribution parameters are calculated as:

\[
\rho_k = \frac{w_k}{S \cdot (b_{k+1} - b_k)} \text{ for } k = 0, \ldots, n-1,
\]

in which the values \( w_k \), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \( 0 < S = w_0 + \cdots + w_{n-1} \).

template<class RealType = double>
class piecewise_constant_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

§ 26.6.8.6.2
// constructor and reset functions
piecewise_constant_distribution();

// constructor and reset functions
template<class InputIteratorB, class InputIteratorW>
piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                   InputIteratorW firstW);

// constructor and reset functions
template<class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

// constructor and reset functions
template<class UnaryOperation>
piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax,
                                   UnaryOperation fw);

explicit piecewise_constant_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);

// generating functions
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
vector<result_type> intervals() const;
vector<result_type> densities() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

piecewise_constant_distribution();

Effects: Constructs a piecewise_constant_distribution object with \( n = 1, \rho_0 = 1, b_0 = 0, \) and \( b_1 = 1. \)

template<class InputIteratorB, class InputIteratorW>
piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                   InputIteratorW firstW);

Mandates: Both of

- is_convertible_v<iterator_traits<InputIteratorB>::value_type, double>
- is_convertible_v<iterator_traits<InputIteratorW>::value_type, double>

are true.

Preconditions: InputIteratorB and InputIteratorW each meet the Cpp17InputIterator requirements (23.3.5.2). If firstB == lastB or ++firstB == lastB, let \( n = 1, w_0 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise, \([firstB, lastB]\) forms a sequence \( b \) of length \( n + 1, \) the length of the sequence \( w \) starting from firstW is at least \( n, \) and any \( w_k \) for \( k \geq n \) are ignored by the distribution.

Effects: Constructs a piecewise_constant_distribution object with parameters as specified above.

template<class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let \( n = 1, w_0 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise, let \([bl.begin(), bl.end()]\) form a sequence \( b_0, \ldots, b_n, \) and let \( w_k = fw((b_{k+1} + b_k)/2) \) for \( k = 0, \ldots, n - 1. \)

Complexity: The number of invocations of \( fw \) does not exceed \( n. \)

template<class UnaryOperation>
piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Preconditions: If \( nw = 0, \) let \( n = 1, \) otherwise let \( n = nw. \) The relation \( 0 < \delta = (xmax - xmin)/n \) holds.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: Let \( b_k = xmin + k \cdot \delta \) for \( k = 0, \ldots, n, \) and \( w_k = fw(b_k + \delta/2) \) for \( k = 0, \ldots, n - 1. \)
13 Complexity: The number of invocations of \( \text{fw} \) does not exceed \( n \).

vector<result_type> intervals() const;

14 Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

vector<result_type> densities() const;

15 Returns: A vector<result_type> whose size member returns \( n \) and whose operator[] member returns \( \rho_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n - 1 \).

26.6.8.6.3 Class template piecewise_linear_distribution

A piecewise_linear_distribution random number distribution produces random numbers \( x \), \( b_0 \leq x < b_n \), distributed over each subinterval \( [b_i, b_{i+1}) \) according to the probability density function

\[
p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_n) = \rho_i \cdot \frac{b_{i+1} - x}{b_i - b_{i+1}} + \rho_{i+1} \cdot \frac{x - b_i}{b_{i+1} - b_i}, \text{ for } b_i \leq x < b_{i+1}.
\]

The \( n + 1 \) distribution parameters \( b_i \), also known as this distribution’s interval boundaries, shall satisfy the relation \( b_i < b_{i+1} \) for \( i = 0, \ldots, n - 1 \). Unless specified otherwise, the remaining \( n + 1 \) distribution parameters are calculated as \( \rho_k = w_k / S \) for \( k = 0, \ldots, n \), in which the values \( w_k \), commonly known as the weights at boundaries, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

\[
0 < S = \frac{1}{2} \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k).
\]

template<class RealType = double>

class piecewise_linear_distribution {

public:

    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    piecewise_linear_distribution();
    template<class InputIteratorB, class InputIteratorW>
        piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                      InputIteratorW firstW);
    template<class UnaryOperation>
        piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
    template<class UnaryOperation>
        piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
    explicit piecewise_linear_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
        result_type operator()(URBG& g);
    template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

    // property functions
    vector<result_type> intervals() const;
    vector<result_type> densities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

piecewise_linear_distribution();

3 Effects: Constructs a piecewise_linear_distribution object with \( n = 1 \), \( \rho_0 = \rho_1 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \).
template<class InputIteratorB, class InputIteratorW>
piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
InputIteratorW firstW);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Preconditions: InputIteratorB and InputIteratorW each meet the Cpp17InputIterator requirements (23.3.5.2).
If firstB == lastB or ++firstB == lastB, let \( n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise,
\([\text{firstB}, \text{lastB}]\) forms a sequence \( b \) of length \( n + 1 \), the length of the sequence \( w \) starting from firstW is at
least \( n + 1 \), and any \( w_k \) for \( k \geq n + 1 \) are ignored by the distribution.

Effects: Constructs a piecewise_linear_distribution object with parameters as specified above.

template<class UnaryOperation>
piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated from
the following values: If \( \text{bl.size()} < 2 \), let \( n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise, let
\([\text{bl.begin()}, \text{bl.end()}]\) form a sequence \( b_0, \ldots, b_n \), and let \( w_k = fw(b_k) \) for \( k = 0, \ldots, n \).

Complexity: The number of invocations of \( fw \) does not exceed \( n + 1 \).

template<class UnaryOperation>
piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Preconditions: If \( nw = 0 \), let \( n = 1 \), otherwise let \( n = nw \). The relation \( 0 < \delta = (xmax - xmin)/n \) holds.

Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated from the
following values: Let \( b_k = xmin + k \cdot \delta \) for \( k = 0, \ldots, n \), and \( w_k = fw(b_k) \) for \( k = 0, \ldots, n \).

Complexity: The number of invocations of \( fw \) does not exceed \( n + 1 \).

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member
returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

vector<result_type> densities() const;

Returns: A vector<result_type> whose size member returns \( n \) and whose operator[] member returns
\( \rho_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

26.6.9 Low-quality random number generation

[Note: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

int rand();
void srand(unsigned int seed);

Effects: The rand and srand functions have the semantics specified in the C standard library.

Remarks: The implementation may specify that particular library functions may call rand. It is implementation-
defined whether the rand function may introduce data races (16.5.5.10). [Note: The other random number
generation facilities in this document (26.6) are often preferable to rand, because rand’s underlying algorithm
is unspecified. Use of rand therefore continues to be non-portable, with unpredictable and oft-questionable
quality and performance. — end note]

template<class T>
unspecified begin(valarray<T>& v);

template<class T>
unspecified begin(const valarray<T>& v);

template<class T>
unspecified end(valarray<T>& v);

template<class T>
unspecified end(const valarray<T>& v);

The header <valarray> defines five class templates (valarray, slice_array, gslice_array, mask_array, and indirect_array), two classes (slice and gslice), and a series of related function templates for representing and manipulating arrays of values.

The valarray array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

Any function returning a valarray<T> is permitted to return an object of another type, provided all the const member functions of valarray<T> are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.\textsuperscript{248}

Implementations introducing such replacement types shall provide additional functions and operators as follows:

\begin{enumerate}[label=(\arabic*), ref=(\arabic*)]
\item for every function taking a const valarray<T>& other than begin and end (26.7.10), identical functions taking the replacement types shall be added;
\item for every function taking two const valarray<T>& arguments, identical functions taking every combination of const valarray<T>& and replacement types shall be added.
\end{enumerate}

In particular, an implementation shall allow a valarray<T> to be constructed from such replacement types and shall allow assignments and compound assignments of such types to valarray<T>, slice_array<T>, gslice_array<T>, mask_array<T> and indirect_array<T> objects.

These library functions are permitted to throw a bad_alloc (17.6.3.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

### 26.7.2 Class template valarray

#### 26.7.2.1 Overview

```cpp
namespace std {
    template<class T> class valarray {
    public:
        using value_type = T;

        // 26.7.2.2, construct/destroy
        valarray();
        explicit valarray(size_t);
        valarray(const T&, size_t);
        valarray(const T*, size_t);
        valarray(const valarray&);
        valarray(valarray&&) noexcept;
        valarray(const slice_array<T>&);
        valarray(const gslice_array<T>&);
        valarray(const mask_array<T>&);
        valarray(const indirect_array<T>&);
        valarray(initializer_list<T>);
        ~valarray();
    }
```
// 26.7.2.3, assignment
valarray& operator=(const valarray&);
valarray& operator=(valarray&&) noexcept;
valarray& operator=(initializer_list<T>);
valarray& operator=(const T&);
valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

// 26.7.2.4, element access
const T& operator[](size_t) const;
T& operator[](size_t);

// 26.7.2.5, subset operations
valarray operator[](slice) const;
slice_array<T> operator[](slice);
valarray operator[](const gslice&) const;
gslice_array<T> operator[](const gslice&);
valarray operator[](const valarray<bool>&) const;
mask_array<T> operator[](const valarray<bool>&);
indirect_array<T> operator[](const valarray<size_t>&) const;
indirect_array<T> operator[](const valarray<size_t>&);

// 26.7.2.6, unary operators
valarray operator+(const T&) const;
valarray operator-(const T&) const;
valarray operator~() const;
valarray operator!() const;

// 26.7.2.7, compound assignment
valarray& operator*=(const T&);
valarray& operator/=(const T&);
valarray& operator%=(const T&);
valarray& operator+=(const T&);
valarray& operator-=(const T&);
valarray& operator^=(const T&);
valarray& operator&=(const T&);
valarray& operator|=(const T&);
valarray& operator<<=(const T&);
valarray& operator>>=(const T&);

// 26.7.2.8, member functions
void swap(valarray&) noexcept;

size_t size() const;
T sum() const;
T min() const;
T max() const;

valarray shift (int) const;
valarray cshift(int) const;
The class template `valarray<T>` is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. For convenience, an object of type `valarray<T>` is referred to as an “array” throughout the remainder of 26.7. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.\footnote{The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporary objects. Thus, the `valarray` template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.}

### 26.7.2.2 Constructors

```cpp
valarray();
```

**Effects:** Constructs a `valarray` that has zero length.\footnote{This default constructor is essential, since arrays of `valarray` may be useful. After initialization, the length of an empty array can be increased with the `resize` member function.}

```cpp
explicit valarray(size_t n);
```

**Effects:** Constructs a `valarray` that has length `n`. Each element of the array is value-initialized (9.4).

```cpp
valarray(const T& v, size_t n);
```

**Effects:** Constructs a `valarray` that has length `n`. Each element of the array is initialized with `v`.

```cpp
valarray(const T* p, size_t n);
```

**Preconditions:** `[p, p + n)` is a valid range.

**Effects:** Constructs a `valarray` that has length `n`. The values of the elements of the array are initialized with the first `n` values pointed to by the first argument.\footnote{This constructor is the preferred method for converting a C array to a `valarray` object.}

```cpp
valarray(const valarray& v);
```

**Effects:** Constructs a `valarray` that has the same length as `v`. The elements are initialized with the values of the corresponding elements of `v`.\footnote{This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they would need to implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.}

```cpp
valarray(valarray&& v) noexcept;
```

**Effects:** Constructs a `valarray` that has the same length as `v`. The elements are initialized with the values of the corresponding elements of `v`.

```cpp
valarray(initializer_list<T> il);
```

**Effects:** Equivalent to `valarray(il.begin(), il.size())`.

```cpp
valarray(const slice_array<T>&);
valarray(const gslice_array<T>&);
valarray(const mask_array<T>&);
valarray(const indirect_array<T>&);
```

These conversion constructors convert one of the four reference templates to a `valarray`.

```cpp
~valarray();
```

**Effects:** The destructor is applied to every element of `*this`; an implementation may return all allocated memory.
26.7.2.3 Assignment  

\[\text{valarray\& operator\=(const valarray\& v);}\]

*Effects:* Each element of the *this array is assigned the value of the corresponding element of v. If the length of v is not equal to the length of *this, resizes *this to make the two arrays the same length, as if by calling resize(v.size()), before performing the assignment.

*Postconditions:* size() == v.size().

*Returns:* *this.

\[\text{valarray\& operator\=(valarray\&\& v) noexcept;}\]

*Effects:* *this obtains the value of v. The value of v after the assignment is not specified.

*Returns:* *this.

*Complexity:* Linear.

\[\text{valarray\& operator\=(initializer_list<T> il);}\]

*Effects:* Equivalent to: return *this = valarray(il);

\[\text{valarray\& operator\=(const T\& v);}\]

*Effects:* Assigns v to each element of *this.

*Returns:* *this.

\[\text{valarray\& operator\=(const slice_array<T>\&);}\]
\[\text{valarray\& operator\=(const gslice_array<T>\&);}\]
\[\text{valarray\& operator\=(const mask_array<T>\&);}\]
\[\text{valarray\& operator\=(const indirect_array<T>\&);}\]

*Preconditions:* The length of the array to which the argument refers equals size(). The value of an element in the left-hand side of a valarray assignment operator does not depend on the value of another element in that left-hand side.

These operators allow the results of a generalized subscripting operation to be assigned directly to a valarray.

26.7.2.4 Element access  

\[\text{const T\& operator\[](size_t n) const;}\]
\[\text{T\& operator\[](size_t n);}\]

*Preconditions:* n < size() is true.

*Returns:* A reference to the corresponding element of the array. [Note: The expression (a[i] = q, a[i]) == q evaluates to true for any non-constant valarray<T> a, any T q, and for any size_t i such that the value of i is less than the length of a. — end note]

*Remarks:* The expression addressof(a[i+j]) == addressof(a[i]) + j evaluates to true for all size_t i and size_t j such that i+j < a.size().

The expression addressof(a[i]) != addressof(b[j]) evaluates to true for any two arrays a and b and for any size_t i and size_t j such that i < a.size() and j < b.size(). [Note: This property indicates an absence of aliasing and may be used to advantage by optimizing compilers. Compilers may take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from operator new, and other techniques to generate efficient valarrays. — end note]

The reference returned by the subscript operator for an array shall be valid until the member function resize(size_t, T) (26.7.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

26.7.2.5 Subset operations  

The member operator[] is overloaded to provide several ways to select sequences of elements from among those controlled by *this. Each of these operations returns a subset of the array. The const-qualified versions return this subset as a new valarray object. The non-const versions return a class template object which has reference semantics to the original array, working in conjunction with various overloads of operator= and other assigning operators to allow selective replacement (slicing) of the controlled sequence. In each case the selected element(s) shall exist.
valarray operator[](slice slicearr) const;

Returns: A valarray containing those elements of the controlled sequence designated by slicearr. [Example:

```c++
const valarray<char> v0("abcdefhijklmnop", 16);
// v0[slice(2, 5, 3)] returns valarray<char>("cfilo", 5)
```
— end example]

slice_array<T> operator[](slice slicearr);

Returns: An object that holds references to elements of the controlled sequence selected by slicearr. [Example:

```c++
valarray<char> v0("abcdefhijklmnop", 16);
valarray<char> v1("ABCDE", 5);
v0[slice(2, 5, 3)] = v1;
// v0 == valarray<char>("abAdeBghCjkDmnEp", 16)
```
— end example]

valarray operator[](const gslice& gslicearr) const;

Returns: A valarray containing those elements of the controlled sequence designated by gslicearr. [Example:

```c++
const valarray<char> v0("abcdefhijklmnop", 16);
const size_t lv[] = { 2, 3 };
const size_t dv[] = { 7, 2 };
const valarray<size_t> len(lv, 2), str(dv, 2);
// v0[gslice(3, len, str)] returns
// valarray<char>("dfhkmo", 6)
```
— end example]

gslice_array<T> operator[](const gslice& gslicearr);

Returns: An object that holds references to elements of the controlled sequence selected by gslicearr.

```c++
valarray<char> v0("abcdefhijklmnop", 16);
valarray<char> v1("ABCDEF", 6);
const size_t lv[] = { 2, 3 };
const size_t dv[] = { 7, 2 };
const valarray<size_t> len(lv, 2), str(dv, 2);
v0[gslice(3, len, str)] = v1;
// v0 == valarray<char>("abcAeBgCijDlEnFp", 16)
```
— end example]

valarray operator[](const valarray<bool>& boolarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by boolarr. [Example:

```c++
const valarray<char> v0("abcdefhijklmnop", 16);
const bool vb[] = { false, false, true, true, false, true };
// v0[valarray<bool>(vb, 6)] returns
// valarray<char>("cdf", 3)
```
— end example]

mask_array<T> operator[](const valarray<bool>& boolarr);

Returns: An object that holds references to elements of the controlled sequence selected by boolarr. [Example:

```c++
valarray<char> v0("abcdefhijklmnop", 16);
valarray<char> v1("ABC", 3);
const bool vb[] = { false, false, true, true, false, true };
v0[valarray<bool>(vb, 6)] = v1;
// v0 == valarray<char>("abaBeCghijklmnop", 16)
```
— end example]
valarray operator[](const valarray<size_t>& indarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by indarr. [Example:
const valarray<char> v0("abcdefgijklmnop", 16);
const size_t vi[] = { 7, 5, 2, 3, 8 };
//v0[valarray<size_t>(vi, 5)] returns
//valarray<char>("hfcdi", 5)
— end example]

indirect_array<T> operator[](const valarray<size_t>& indarr);

Returns: An object that holds references to elements of the controlled sequence selected by indarr. [Example:
valarray<char> v0("abcdefgijklmnop", 16);
valarray<char> v1("ABCDE", 5);
const size_t vi[] = { 7, 5, 2, 3, 8 };
v0[valarray<size_t>(vi, 5)] = v1;
//v0 == valarray<char>("abcDeBgAEjklmnop", 16)
— end example]

26.7.2.6 Unary operators

valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T (bool for operator!) or which may be unambiguously implicitly converted to type T (bool for operator!).

Returns: A valarray whose length is size(). Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

26.7.2.7 Compound assignment

valarray& operator*=(const valarray& v);
valarray& operator/=(const valarray& v);
valarray& operator%=(const valarray& v);
valarray& operator+=(const valarray& v);
valarray& operator-=(const valarray& v);
valarray& operator^=(const valarray& v);
valarray& operator&=(const valarray& v);
valarray& operator|=(const valarray& v);
valarray& operator<<=(const valarray& v);
valarray& operator>>=(const valarray& v);

Mandates: The indicated operator can be applied to two operands of type T.

Preconditions: size() == v.size() is true.

The value of an element in the left-hand side of a valarray compound assignment operator does not depend on the value of another element in that left hand side.

Effects: Each of these operators performs the indicated operation on each of the elements of *this and the corresponding element of v.

Returns: *this.

Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers.
valarray & operator<<=(const T& v);
valarray & operator>>=(const T& v);

Mandates: The indicated operator can be applied to two operands of type T.
Effects: Each of these operators applies the indicated operation to each element of *this and v.
Returns: *this
Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers to the elements of the array.

26.7.2.8 Member functions

void swap(valarray & v) noexcept;

Effects: *this obtains the value of v. v obtains the value of *this.
Complexity: Constant.

size_t size() const;

Returns: The number of elements in the array.
Complexity: Constant time.

T sum() const;

Mandates: operator+= can be applied to operands of type T.
Preconditions: size() > 0 is true.
Returns: The sum of all the elements of the array. If the array has length 1, returns the value of element 0. Otherwise, the returned value is calculated by applying operator+= to a copy of an element of the array and all other elements of the array in an unspecified order.

T min() const;

Preconditions: size() > 0 is true.
Returns: The minimum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

T max() const;

Preconditions: size() > 0 is true.
Returns: The maximum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

valarray shift(int n) const;

Returns: A valarray of length size(), each of whose elements I is (*this)[I + n] if I + n is non-negative and less than size(), otherwise T(). [Note: If element zero is taken as the leftmost element, a positive value of n shifts the elements left n places, with zero fill. — end note]
[Example: If the argument has the value -2, the first two elements of the result will be value-initialized (9.4); the third element of the result will be assigned the value of the first element of the argument; etc. — end example]

valarray cshift(int n) const;

Returns: A valarray of length size() that is a circular shift of *this. If element zero is taken as the leftmost element, a non-negative value of n shifts the elements circularly left n places and a negative value of n shifts the elements circularly right −n places.

valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;

Returns: A valarray whose length is size(). Each element of the returned array is assigned the value returned by applying the argument function to the corresponding element of *this.

void resize(size_t sz, T c = T());

Effects: Changes the length of the *this array to sz and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.
26.7.3 valarray non-member operations [valarray.nonmembers]

26.7.3.1 Binary operators [valarray.binary]

template<class T> valarray<T> operator* (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator/ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator% (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator+ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator- (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator^ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator& (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator| (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator<<(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator>>(const valarray<T>&, const valarray<T>&);

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T or which can be unambiguously implicitly converted to T.

Preconditions: The argument arrays have the same length.

Returns: A valarray whose length is equal to the lengths of the argument arrays. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T or which can be unambiguously implicitly converted to T.
Returns: A valarray whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array argument and the non-array argument.

26.7.3.2 Logical operators

\[\text{template<class T> valarray<bool> operator== (const valarray<T>&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator!= (const valarray<T>&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator< (const valarray<T>&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator> (const valarray<T>&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator<=(const valarray<T>&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator>=(const valarray<T>&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator&&(const valarray<T>&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator||(const valarray<T>&, const valarray<T>&);}\]

Mandates: The indicated operator can be applied to operands of type T and returns a value of type bool or which can be unambiguously implicitly converted to bool.

Preconditions: The two array arguments have the same length.

Returns: A valarray<bool> whose length is equal to the length of the array arguments. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

\[\text{template<class T> valarray<bool> operator== (const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator== (const typename valarray<T>::value_type&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator!= (const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator!= (const typename valarray<T>::value_type&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator< (const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator< (const typename valarray<T>::value_type&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator> (const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator> (const typename valarray<T>::value_type&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator<=(const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator<=(const typename valarray<T>::value_type&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator>=(const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator>=(const typename valarray<T>::value_type&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator&&(const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator&&(const typename valarray<T>::value_type&, const valarray<T>&);}\]
\[\text{template<class T> valarray<bool> operator||(const valarray<T>&, const typename valarray<T>::value_type&);}\]
\[\text{template<class T> valarray<bool> operator||(const typename valarray<T>::value_type&, const valarray<T>&);}\]

Mandates: The indicated operator can be applied to operands of type T and returns a value of type bool or which can be unambiguously implicitly converted to bool.

Returns: A valarray<bool> whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array and the non-array argument.

26.7.3.3 Transcendentals

\[\text{template<class T> valarray<T> abs (const valarray<T>&);}\]
template<class T> valarray<T> acos (const valarray<T>&);
template<class T> valarray<T> asin (const valarray<T>&);
template<class T> valarray<T> atan (const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> atan2(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> cos (const valarray<T>&);
template<class T> valarray<T> cosh (const valarray<T>&);
template<class T> valarray<T> exp (const valarray<T>&);
template<class T> valarray<T> log (const valarray<T>&);
template<class T> valarray<T> log10(const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> pow (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> sin (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);

1  

Mandates: A unique function with the indicated name can be applied (unqualified) to an operand of type T. This function returns a value of type T or which can be unambiguously implicitly converted to type T.

26.7.3.4 Specialized algorithms

template<class T> void swap(valarray<T>& x, valarray<T>& y) noexcept;

1  

Effects: Equivalent to x.swap(y).

26.7.4 Class slice

26.7.4.1 Overview

namespace std {
    class slice {
        public:
            slice();
            slice(size_t start, size_t length, size_t stride);
            size_t start() const;
            size_t size() const;
            size_t stride() const;

            friend bool operator==(const slice& x, const slice& y);
    };
}

1  

The slice class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride.\footnote{BLAS stands for Basic Linear Algebra Subprograms. C++ programs may instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: A set of Level 3 Basic Linear Algebra Subprograms; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.}

26.7.4.2 Constructors

slice();
slice(size_t start, size_t length, size_t stride);
slice(const slice&);

1  

The default constructor is equivalent to slice(0, 0, 0). A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

2  

[Example: slice(3, 8, 2) constructs a slice which selects elements 3, 5, 7, \ldots, 17 from an array. – end example]
26.7.4.3 Access functions

size_t start() const;
size_t size() const;
size_t stride() const;

1 Returns: The start, length, or stride specified by a slice object.
2 Complexity: Constant time.

26.7.4.4 Operators

friend bool operator==(const slice& x, const slice& y);

1 Effects: Equivalent to:
   return x.start() == y.start() && x.size() == y.size() && x.stride() == y.stride();

26.7.5 Class template slice_array

26.7.5.1 Overview

namespace std {
    template<class T> class slice_array {
        public:
            using value_type = T;

            void operator= (const valarray<T>&) const;
            void operator*= (const valarray<T>&) const;
            void operator/= (const valarray<T>&) const;
            void operator%= (const valarray<T>&) const;
            void operator+= (const valarray<T>&) const;
            void operator-= (const valarray<T>&) const;
            void operator^= (const valarray<T>&) const;
            void operator&= (const valarray<T>&) const;
            void operator|= (const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;
            void operator>>=(const valarray<T>&) const;
            slice_array(const slice_array&);
            ~slice_array();
            const slice_array& operator=(const slice_array&) const;
            void operator=(const T&) const;
            slice_array() = delete; // as implied by declaring copy constructor above
    };
}

1 This template is a helper template used by the slice subscript operator
   slice_array<T> valarray<T>::operator[](slice);

2 It has reference semantics to a subset of an array specified by a slice object. [Example: The expression a[slice(1, 5, 3)] = b; has the effect of assigning the elements of b to a slice of the elements in a. For the slice shown, the elements selected from a are 1, 4, ..., 13. — end example]

26.7.5.2 Assignment

void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which the slice_array object refers.

26.7.5.3 Compound assignment

void operator==(const valarray<T>&) const;
void operator=/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the \texttt{valarray<T>} object to which the \texttt{slice_array} object refers.

26.7.5.4 Fill function

\begin{verbatim}
void operator=(const T&) const;
\end{verbatim}

This function has reference semantics, assigning the value of its argument to the elements of the \texttt{valarray<T>} object to which the \texttt{slice_array} object refers.

26.7.6 The \texttt{gslice} class

26.7.6.1 Overview

\begin{verbatim}
namespace std {
class gslice {
public:
  gslice();
  gslice(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);

  size_t start() const;
  valarray<size_t> size() const;
  valarray<size_t> stride() const;
};
}
\end{verbatim}

This class represents a generalized slice out of an array. A \texttt{gslice} is defined by a starting offset \((s)\), a set of lengths \((l_j)\), and a set of strides \((d_j)\). The number of lengths shall equal the number of strides.

A \texttt{gslice} represents a mapping from a set of indices \((i_j)\), equal in number to the number of strides, to a single index \(k\). It is useful for building multidimensional array classes using the \texttt{valarray} template, which is one-dimensional. The set of one-dimensional index values specified by a \texttt{gslice} are

\[ k = s + \sum_i i_d j \]

where the multidimensional indices \(i_j\) range in value from 0 to \(l_{ij} - 1\).

[Example: The \texttt{gslice} specification]

\begin{verbatim}
start = 3
length = {2, 4, 3}
stride = {19, 4, 1}
\end{verbatim}

yields the sequence of one-dimensional indices

\[ k = 3 + (0, 1) \times 19 + (0, 1, 2, 3) \times 4 + (0, 1, 2) \times 1 \]

which are ordered as shown in the following table:

\begin{align*}
(i_0, & i_1, i_2, k) = \\
(0, & 0, 0, 3),
(0, & 0, 1, 4),
(0, & 0, 2, 5),
(0, & 1, 0, 7),
(0, & 1, 1, 8),
(0, & 1, 2, 9),
(0, & 2, 0, 11),
(0, & 2, 1, 12),
(0, & 2, 2, 13),
(0, & 3, 0, 15),
(0, & 3, 1, 16),
\end{align*}
That is, the highest-ordered index turns fastest. — end example]

4 It is possible to have degenerate generalized slices in which an address is repeated.

5 [Example: If the stride parameters in the previous example are changed to \(\{1, 1, 1\}\), the first few elements of the resulting sequence of indices will be

\[
(0, 0, 0, 3), \\
(0, 0, 1, 4), \\
(0, 0, 2, 5), \\
(0, 1, 0, 4), \\
(0, 1, 1, 5), \\
(0, 1, 2, 6), \\
\ldots
\]

— end example]

6 If a degenerate slice is used as the argument to the non-const version of \texttt{operator[]} (const gslice&), the behavior is undefined.

26.7.6.2 Constructors 

\texttt{gslice()};
\texttt{gslice(size_t \_start, const valarray\langle size_t\rangle& \_lengths, \\
const valarray\langle size_t\rangle& \_strides);}
\texttt{gslice(const gslice&);}  

The default constructor is equivalent to \texttt{gslice(0, valarray\langle size_t\rangle(), valarray\langle size_t\rangle())}. The constructor with arguments builds a \texttt{gslice} based on a specification of start, lengths, and strides, as explained in the previous subclause.

26.7.6.3 Access functions

\texttt{size_t \_start() const;}
\texttt{valarray\langle size_t\rangle \_size() const;}
\texttt{valarray\langle size_t\rangle \_stride() const;}

1 Returns: The representation of the start, lengths, or strides specified for the \texttt{gslice}.

2 Complexity: \texttt{start()} is constant time. \texttt{size()} and \texttt{stride()} are linear in the number of strides.

26.7.7 Class template \texttt{gslice\_array} 

26.7.7.1 Overview

\texttt{namespace std {
\template<class T> class gslice\_array {
public:
\using value\_type = T;

\texttt{void operator\*= (const valarray\langle T\rangle& \_r) const;}
\texttt{void operator\%= (const valarray\langle T\rangle& \_r) const;}
\texttt{void operator\^= (const valarray\langle T\rangle& \_r) const;}
\texttt{void operator&= (const valarray\langle T\rangle& \_r) const;}
\texttt{void operator|= (const valarray\langle T\rangle& \_r) const;}
\texttt{void operator<<= (const valarray\langle T\rangle& \_r) const;}
\texttt{void operator>>= (const valarray\langle T\rangle& \_r) const;}

\texttt{}}
\template}}
gslice_array(const gslice_array&);
~gslice_array();
const gslice_array& operator=(const gslice_array&) const;
void operator=(const T&) const;

gslice_array() = delete; // as implied by declaring copy constructor above
};

1 This template is a helper template used by the gslice subscript operator

gslice_array<T> valarray<T>::operator[](const gslice&);

2 It has reference semantics to a subset of an array specified by a gslice object. Thus, the expression a[gslice(1, length, stride)] = b has the effect of assigning the elements of b to a generalized slice of the elements in a.

### 26.7.7.2 Assignment

void operator=(const valarray<T>&) const;
const gslice_array& operator=(const gslice_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which the gslice_array refers.

### 26.7.7.3 Compound assignment

void operator==(const valarray<T>&) const;
void operator!=(const valarray<T>&) const;
void operator%=(const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the gslice_array object refers.

### 26.7.7.4 Fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the gslice_array object refers.

### 26.7.8 Class template mask_array

### 26.7.8.1 Overview

namespace std {
    template<class T> class mask_array {
        public:
            using value_type = T;

            void operator==(const valarray<T>&) const;
            void operator+=(const valarray<T>&) const;
            void operator%=(const valarray<T>&) const;
            void operator-= (const valarray<T>&) const;
            void operator&=(const valarray<T>&) const;
            void operator|=(const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;
            void operator>>=(const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;

§ 26.7.8.1 1180
mask_array(const mask_array&);
~mask_array();
const mask_array& operator=(const mask_array&) const;
void operator=(const T&) const;
mask_array() = delete;  // as implied by declaring copy constructor above
};

1 This template is a helper template used by the mask subscript operator:

mask_array<T> valarray<T>::operator[] (const valarray<bool>&).

2 It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression `a[mask] = b;`
has the effect of assigning the elements of `b` to the masked elements in `a` (those for which the corresponding element
in `mask` is true).

26.7.8.2 Assignment [mask.array.assign]

void operator=(const valarray<T>&) const;
const mask_array& operator=(const mask_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array elements to
selected elements of the `valarray<T>` object to which the `mask_array` object refers.

26.7.8.3 Compound assignment [mask.array.comp.assign]

void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of
the argument array and selected elements of the `valarray<T>` object to which the `mask_array` object refers.

26.7.8.4 Fill function [mask.array.fill]

void operator=(const T& ) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>`
object to which the `mask_array` object refers.

26.7.9 Class template indirect_array [template.indirect.array]

26.7.9.1 Overview [template.indirect.array.overview]

namespace std {  
  template<class T> class indirect_array {  
public:
    using value_type = T;
    
    void operator=(const valarray<T>&) const;
    void operator+=(const valarray<T>&) const;
    void operator-=(const valarray<T>&) const;
  
  };
indirect_array(const indirect_array&);
~indirect_array();
const indirect_array& operator=(const indirect_array&) const;
void operator=(const Tk) const;

indirect_array() = delete;  // as implied by declaring copy constructor above

1 This template is a helper template used by the indirect subscript operator

indirect_array<T> valarray<T>::operator[](const valarray<size_t>&).

2 It has reference semantics to a subset of an array specified by an indirect_array. Thus, the expression a[indirect] = b; has the effect of assigning the elements of b to the elements in a whose indices appear in indirect.

26.7.9.2 Assignment

void operator=(const valarray<T>&) const;
const indirect_array& operator=(const indirect_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which it refers.

2 If the indirect_array specifies an element in the valarray<T> object to which it refers more than once, the behavior is undefined.

[Example:
int addr[] = {2, 3, 1, 4, 4};
valarray<size_t> indirect(addr, 5);
valarray<double> a(0., 10), b(1., 5);
a[indirect] = b;
results in undefined behavior since element 4 is specified twice in the indirection. — end example]

26.7.9.3 Compound assignment

void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the indirect_array object refers.

2 If the indirect_array specifies an element in the valarray<T> object to which it refers more than once, the behavior is undefined.

26.7.9.4 Fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the indirect_array object refers.

26.7.10 valarray range access

In the begin and end function templates that follow, unspecified1 is a type that meets the requirements of a mutable Cpp17RandomAccessIterator (23.3.5.6) and models contiguous_iterator (23.3.4.14), whose value_type is the template parameter T and whose reference type is Tk. unspecified2 is a type that meets the requirements of a constant Cpp17RandomAccessIterator and models contiguous_iterator, whose value_type is the template parameter T and whose reference type is const Tk.
The iterators returned by `begin` and `end` for an array are guaranteed to be valid until the member function `resize(size_t, T)` (26.7.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

```cpp
template<class T> unspecified1 begin(valarray<T>& v);
template<class T> unspecified2 begin(const valarray<T>& v);
```

*Returns:* An iterator referencing the first value in the array.

```cpp
template<class T> unspecified1 end(valarray<T>& v);
template<class T> unspecified2 end(const valarray<T>& v);
```

*Returns:* An iterator referencing one past the last value in the array.

### 26.8 Mathematical functions for floating-point types

#### [c.math]

float sph_legendref(unsigned l, unsigned m, float theta);
long double sph_legendrel(unsigned l, unsigned m, long double theta);

§ 26.8.1

1 The contents and meaning of the header `<cmath>` are the same as the C standard library header `<math.h>`, with the addition of a three-dimensional hypotenuse function (26.8.3) and the mathematical special functions described in 26.8.6. [Note: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2). — end note]  

2 For each set of overloaded functions within `<cmath>`, with the exception of `abs`, there shall be additional overloads sufficient to ensure:

(2.1) — If any argument of arithmetic type corresponding to a `double` parameter has type `long double`, then all arguments of arithmetic type (6.8.1) corresponding to `double` parameters are effectively cast to `long double`.

(2.2) — Otherwise, if any argument of arithmetic type corresponding to a `double` parameter has type `double` or an integer type, then all arguments of arithmetic type corresponding to `double` parameters are effectively cast to `double`.

(2.3) — [Note: Otherwise, all arguments of arithmetic type corresponding to `double` parameters have type `float`. — end note]
## 26.8.2 Absolute values

**[c.math.abs]**

[Note: The headers `<cstdlib>` (17.2.2) and `<cmath>` (26.8.1) declare the functions described in this subclause. — end note]

```c
int abs(int j);
long int abs(long int j);
long long int abs(long long int j);
float abs(float j);
double abs(double j);
long double abs(long double j);
```

**Effects:** The `abs` functions have the semantics specified in the C standard library for the functions `abs`, `labs`, `llabs`, `fabsf`, `fabs`, and `fabsl`.

**Remarks:** If `abs()` is called with an argument of type `X` for which `is_unsigned_v<X>` is true and if `X` cannot be converted to `int` by integral promotion (7.3.6), the program is ill-formed. [Note: Arguments that can be promoted to `int` are permitted for compatibility with C. — end note]

See also: ISO C 7.12.7.2, 7.22.6.1

## 26.8.3 Three-dimensional hypotenuse

**[c.math.hypot3]**

```c
float hypot(float x, float y, float z);
double hypot(double x, double y, double z);
long double hypot(long double x, long double y, long double z);
```

**Returns:** \( \sqrt{x^2 + y^2 + z^2} \).

## 26.8.4 Linear interpolation

**[c.math.lerp]**

```c
constexpr float lerp(float a, float b, float t) noexcept;
constexpr double lerp(double a, double b, double t) noexcept;
constexpr long double lerp(long double a, long double b, long double t) noexcept;
```

**Returns:** \( a + t(b - a) \).

**Remarks:** Let \( r \) be the value returned. If `isfinite(a) && isfinite(b)`, then:

1. If \( t == 0 \), then \( r == a \).
2. If \( t == 1 \), then \( r == b \).
3. If \( t >= 0 && t <= 1 \), then `isfinite(r)`.
4. If `isfinite(t) && a == b`, then \( r == a \).
5. If `isfinite(t) && !isnan(t) && b-a != 0`, then `!isnan(r)`.

Let \( CMP(x, y) = 1 \) if \( x > y \), \(-1 \) if \( x < y \), and 0 otherwise. For any \( t1 \) and \( t2 \), the product of \( CMP(lerp(a, b, t2), lerp(a, b, t1)) \), \( CMP(t2, t1) \), and \( CMP(b, a) \) is non-negative.

## 26.8.5 Classification / comparison functions

**[c.math.fpclass]**

The classification / comparison functions behave the same as the C macros with the corresponding names defined in the C standard library. Each function is overloaded for the three floating-point types.

See also: ISO C 7.12.3, 7.12.4

## 26.8.6 Mathematical special functions

**[sf.cmath]**

If any argument value to any of the functions specified in this subclause is a NaN (Not a Number), the function shall return a NaN but it shall not report a domain error. Otherwise, the function shall report a domain error for just those argument values for which:

1. The function description’s `Returns` element explicitly specifies a domain and those argument values fall outside the specified domain, or
2. the corresponding mathematical function value has a nonzero imaginary component, or
the corresponding mathematical function is not mathematically defined.\footnote{A mathematical function is mathematically defined for a given set of argument values (a) if it is explicitly defined for that set of argument values, or (b) if its limiting value exists and does not depend on the direction of approach.} Unless otherwise specified, each function is defined for all finite values, for negative infinity, and for positive infinity.

26.8.6.1 Associated Laguerre polynomials [sf.cmath.assoc.laguerre]

```c
double assoc_laguerre(unsigned n, unsigned m, double x);
float assoc_laguerref(unsigned n, unsigned m, float x);
long double assoc_laguerrel(unsigned n, unsigned m, long double x);
```

1. **Effects:** These functions compute the associated Laguerre polynomials of their respective arguments \(n\), \(m\), and \(x\).

2. **Returns:**

\[ L_n^m(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x), \quad \text{for } x \geq 0, \]

where \(n\) is \(n\), \(m\) is \(m\), and \(x\) is \(x\).

3. **Remarks:** The effect of calling each of these functions is implementation-defined if \(n \geq 128\) or if \(m \geq 128\).

26.8.6.2 Associated Legendre functions [sf.cmath.assoc.legendre]

```c
double assoc_legendre(unsigned l, unsigned m, double x);
float assoc_legendref(unsigned l, unsigned m, float x);
long double assoc_legendrel(unsigned l, unsigned m, long double x);
```

1. **Effects:** These functions compute the associated Legendre functions of their respective arguments \(l\), \(m\), and \(x\).

2. **Returns:**

\[ P_l^m(x) = (1-x^2)^{m/2} \frac{d^m}{dx^m} P_l(x), \quad \text{for } |x| \leq 1, \]

where \(l\) is \(l\), \(m\) is \(m\), and \(x\) is \(x\).

3. **Remarks:** The effect of calling each of these functions is implementation-defined if \(l \geq 128\).

26.8.6.3 Beta function [sf.cmath.beta]

```c
double beta(double x, double y);
float betaf(float x, float y);
long double betal(long double x, long double y);
```

1. **Effects:** These functions compute the beta function of their respective arguments \(x\) and \(y\).

2. **Returns:**

\[ B(x, y) = \frac{\Gamma(x) \Gamma(y)}{\Gamma(x+y)}, \quad \text{for } x > 0, \ y > 0, \]

where \(x\) is \(x\) and \(y\) is \(y\).

26.8.6.4 Complete elliptic integral of the first kind [sf.cmath.comp.ellint.1]

```c
double comp_ellint_1(double k);
float comp_ellint_1f(float k);
long double comp_ellint_1l(long double k);
```

1. **Effects:** These functions compute the complete elliptic integral of the first kind of their respective arguments \(k\).

2. **Returns:**

\[ K(k) = F(k, \pi/2), \quad \text{for } |k| \leq 1, \]

where \(k\) is \(k\).

3. **Remarks:** The effect of calling each of these functions is implementation-defined if \(1 \geq 128\).

\footnote{A mathematical function is mathematically defined for a given set of argument values (a) if it is explicitly defined for that set of argument values, or (b) if its limiting value exists and does not depend on the direction of approach.}
26.8.6.5 Complete elliptic integral of the second kind

\texttt{double \ comp\_ellint\_2(double k);}  \
\texttt{float \ comp\_ellint\_2f(float k);}  \
\texttt{long double \ comp\_ellint\_2l(long double k);}  \\
1 \quad \textbf{Effects}: These functions compute the complete elliptic integral of the second kind of their respective arguments \( k \).

2 \quad \textbf{Returns}: \( E(k) = E(k, \pi/2) \), for \(|k| \leq 1\),

where \( k \) is \( k \).

3 \quad \textbf{See also} 26.8.6.12.

26.8.6.6 Complete elliptic integral of the third kind

\texttt{double \ comp\_ellint\_3(double k, double \nu);}  \
\texttt{float \ comp\_ellint\_3f(float k, float \nu);}  \
\texttt{long double \ comp\_ellint\_3l(long double k, long double \nu);}  \\
1 \quad \textbf{Effects}: These functions compute the complete elliptic integral of the third kind of their respective arguments \( k \) and \( \nu \).

2 \quad \textbf{Returns}: \( \Pi(\nu, k) = \Pi(\nu, k, \pi/2) \), for \(|k| \leq 1\),

where \( k \) is \( k \) and \( \nu \) is \( \nu \).

3 \quad \textbf{See also} 26.8.6.13.

26.8.6.7 Regular modified cylindrical Bessel functions

\texttt{double \ cyl\_bessel\_i(double \nu, double x);}  \
\texttt{float \ cyl\_bessel\_if(float \nu, float x);}  \
\texttt{long double \ cyl\_bessel\_il(long double \nu, long double x);}  \\
1 \quad \textbf{Effects}: These functions compute the regular modified cylindrical Bessel functions of their respective arguments \( \nu \) and \( x \).

2 \quad \textbf{Returns}: \( I_\nu(x) = i^{-\nu}J_\nu(ix) = \sum_{k=0}^{\infty} \frac{(x/2)^{\nu+2k}}{k!\Gamma(\nu+k+1)} \), for \( x \geq 0 \),

where \( \nu \) is \( \nu \) and \( x \) is \( x \).

3 \quad \textbf{Remarks}: The effect of calling each of these functions is implementation-defined if \( \nu >= 128 \).

4 \quad \textbf{See also} 26.8.6.8.

26.8.6.8 Cylindrical Bessel functions of the first kind

\texttt{double \ cyl\_bessel\_j(double \nu, double x);}  \
\texttt{float \ cyl\_bessel\_jf(float \nu, float x);}  \
\texttt{long double \ cyl\_bessel\_jl(long double \nu, long double x);}  \\
1 \quad \textbf{Effects}: These functions compute the cylindrical Bessel functions of the first kind of their respective arguments \( \nu \) and \( x \).

2 \quad \textbf{Returns}: \( J_\nu(x) = \sum_{k=0}^{\infty} \frac{(-1)^k(x/2)^{\nu+2k}}{k!\Gamma(\nu+k+1)} \), for \( x \geq 0 \),

where \( \nu \) is \( \nu \) and \( x \) is \( x \).

3 \quad \textbf{Remarks}: The effect of calling each of these functions is implementation-defined if \( \nu >= 128 \).
26.8.6.9 Irregular modified cylindrical Bessel functions

```c
double cyl_bessel_k(double nu, double x);
float cyl_bessel_kf(float nu, float x);
long double cyl_bessel_kl(long double nu, long double x);
```

1. **Effects:** These functions compute the irregular modified cylindrical Bessel functions of their respective arguments \(nu\) and \(x\).

2. **Returns:**

\[
K_\nu(x) = (\pi/2)^{\nu+1}(J_\nu(ix) + iN_\nu(ix)) = \begin{cases} 
\frac{\pi}{2} \frac{1_{-\nu}(x) - 1_\nu(x)}{\sin \nu \pi}, & \text{for } x \geq 0 \text{ and non-integral } \nu \\
\frac{\pi}{2} \lim_{\mu \to \nu} \frac{1_\mu(x) - 1_{-\mu}(x)}{\sin \mu \pi}, & \text{for } x \geq 0 \text{ and integral } \nu
\end{cases}
\]

where \(\nu\) is \(nu\) and \(x\) is \(x\).

3. **Remarks:** The effect of calling each of these functions is implementation-defined if \(nu \geq 128\).

4. See also 26.8.6.8, 26.8.6.10.

---

26.8.6.10 Cylindrical Neumann functions

```c
double cyl_neumann(double nu, double x);
float cyl_neumannf(float nu, float x);
long double cyl_neumannl(long double nu, long double x);
```

1. **Effects:** These functions compute the cylindrical Neumann functions, also known as the cylindrical Bessel functions of the second kind, of their respective arguments \(nu\) and \(x\).

2. **Returns:**

\[
N_\nu(x) = \begin{cases} 
\frac{J_\nu(x) \cos \nu \pi - J_{-\nu}(x)}{\sin \nu \pi}, & \text{for } x \geq 0 \text{ and non-integral } \nu \\
\lim_{\mu \to \nu} \frac{J_\mu(x) \cos \mu \pi - J_{-\mu}(x)}{\sin \mu \pi}, & \text{for } x \geq 0 \text{ and integral } \nu
\end{cases}
\]

where \(\nu\) is \(nu\) and \(x\) is \(x\).

3. **Remarks:** The effect of calling each of these functions is implementation-defined if \(nu \geq 128\).

4. See also 26.8.6.8.

---

26.8.6.11 Incomplete elliptic integral of the first kind

```c
double ellint_1(double k, double phi);
float ellint_1f(float k, float phi);
long double ellint_1l(long double k, long double phi);
```

1. **Effects:** These functions compute the incomplete elliptic integral of the first kind of their respective arguments \(k\) and \(phi\) (\(phi\) measured in radians).

2. **Returns:**

\[
F(k, \phi) = \int_0^\phi \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}, \text{ for } |k| \leq 1,
\]

where \(k\) is \(k\) and \(\phi\) is \(phi\).

---

26.8.6.12 Incomplete elliptic integral of the second kind

```c
double ellint_2(double k, double phi);
float ellint_2f(float k, float phi);
long double ellint_2l(long double k, long double phi);
```

1. **Effects:** These functions compute the incomplete elliptic integral of the second kind of their respective arguments \(k\) and \(phi\) (\(phi\) measured in radians).

2. **Returns:**

\[
E(k, \phi) = \int_0^\phi \sqrt{1 - k^2 \sin^2 \theta} d\theta, \text{ for } |k| \leq 1,
\]

where \(k\) is \(k\) and \(\phi\) is \(phi\).
26.8.6.13 Incomplete elliptic integral of the third kind

\[
double \ ellint_3(double k, double nu, double phi);
float \ ellint_3f(float k, float nu, float phi);
long double \ ellint_3l(long double k, long double nu, long double phi);
\]

1 Effects: These functions compute the incomplete elliptic integral of the third kind of their respective arguments \(k\), \(nu\), and \(phi\) (\(phi\) measured in radians).

2 Returns:

\[
\Pi(\nu, k, \phi) = \int_0^\phi \frac{d\theta}{(1 - \nu \sin^2 \theta)\sqrt{1 - k^2 \sin^2 \theta}}, \quad \text{for } |k| \leq 1,
\]

where \(\nu\) is \(nu\), \(k\) is \(k\), and \(\phi\) is \(phi\).

26.8.6.14 Exponential integral

\[
double \ expint(double x);
float \ expintf(float x);
long double \ expintl(long double x);
\]

1 Effects: These functions compute the exponential integral of their respective arguments \(x\).

2 Returns:

\[
Ei(x) = -\int_\infty^{-x} \frac{e^{-t}}{t} \, dt
\]

where \(x\) is \(x\).

26.8.6.15 Hermite polynomials

\[
double \ hermite(unsigned n, double x);
float \ hermitef(unsigned n, float x);
long double \ hermitel(unsigned n, long double x);
\]

1 Effects: These functions compute the Hermite polynomials of their respective arguments \(n\) and \(x\).

2 Returns:

\[
H_n(x) = (-1)^n e^{-x^2} \frac{d^n}{dx^n} e^{-x^2}
\]

where \(n\) is \(n\) and \(x\) is \(x\).

3 Remarks: The effect of calling each of these functions is implementation-defined if \(n \geq 128\).

26.8.6.16 Laguerre polynomials

\[
double \ laguerre(unsigned n, double x);
float \ laguerref(unsigned n, float x);
long double \ laguerrrel(unsigned n, long double x);
\]

1 Effects: These functions compute the Laguerre polynomials of their respective arguments \(n\) and \(x\).

2 Returns:

\[
L_n(x) = \frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x}), \quad \text{for } x \geq 0,
\]

where \(n\) is \(n\) and \(x\) is \(x\).

3 Remarks: The effect of calling each of these functions is implementation-defined if \(n \geq 128\).

26.8.6.17 Legendre polynomials

\[
double \ legendre(unsigned l, double x);
float \ legendref(unsigned l, float x);
long double \ legendrel(unsigned l, long double x);
\]

1 Effects: These functions compute the Legendre polynomials of their respective arguments \(l\) and \(x\).

2 Returns:

\[
P_l(x) = \frac{1}{2^l l!} \frac{d^l}{dx^l} (x^2 - 1)^l, \quad \text{for } |x| \leq 1,
\]

where \(l\) is \(l\) and \(x\) is \(x\).

3 Remarks: The effect of calling each of these functions is implementation-defined if \(l \geq 128\).
26.8.6.18 Riemann zeta function

```c
double riemann_zeta(double x);
float riemann_zetaf(float x);
long double riemann_zetal(long double x);
```

**Effects:** These functions compute the Riemann zeta function of their respective arguments $x$.

**Returns:**

\[ \zeta(x) = \begin{cases} 
\sum_{k=1}^{\infty} k^{-x}, & \text{for } x > 1 \\
\frac{1}{1-2^{1-x}} \sum_{k=1}^{\infty} (-1)^{k-1} k^{-x}, & \text{for } 0 \leq x \leq 1 \\
2^{-x} \pi^{x-1} \sin \left( \frac{\pi x}{2} \right) \Gamma(1-x) \zeta(1-x), & \text{for } x < 0
\end{cases} \]

where $x$ is $x$.

26.8.6.19 Spherical Bessel functions of the first kind

```c
double sph_bessel(unsigned n, double x);
float sph_besself(unsigned n, float x);
long double sph_bessell(unsigned n, long double x);
```

**Effects:** These functions compute the spherical Bessel functions of the first kind of their respective arguments $n$ and $x$.

**Returns:**

\[ j_n(x) = \left( \frac{\pi}{2x} \right)^{1/2} J_{n+1/2}(x), \text{ for } x \geq 0, \]

where $n$ is $n$ and $x$ is $x$.

**Remarks:** The effect of calling each of these functions is implementation-defined if $n \geq 128$.

See also 26.8.6.8.

26.8.6.20 Spherical associated Legendre functions

```c
double sph_legendre(unsigned l, unsigned m, double theta);
float sph_legendref(unsigned l, unsigned m, float theta);
long double sph_legendrel(unsigned l, unsigned m, long double theta);
```

**Effects:** These functions compute the spherical associated Legendre functions of their respective arguments $l$, $m$, and $\theta$ ($\theta$ measured in radians).

**Returns:**

\[ Y^m_l(\theta, 0) \]

where

\[ Y^m_l(\theta, \phi) = (-1)^m \left[ \frac{(2\ell + 1)(\ell - m)!}{4\pi (\ell + m)!} \right]^{1/2} P^m_\ell(\cos \theta) e^{im\phi}, \text{ for } |m| \leq \ell, \]

and $l$ is $l$, $m$ is $m$, and $\theta$ is $\theta$.

**Remarks:** The effect of calling each of these functions is implementation-defined if $l \geq 128$.

See also 26.8.6.2.

26.8.6.21 Spherical Neumann functions

```c
double sph_neumann(unsigned n, double x);
float sph_neumannf(unsigned n, float x);
long double sph_neumannl(unsigned n, long double x);
```

**Effects:** These functions compute the spherical Neumann functions, also known as the spherical Bessel functions of the second kind, of their respective arguments $n$ and $x$.

**Returns:**

\[ n_n(x) = \left( \frac{\pi}{2x} \right)^{1/2} N_{n+1/2}(x), \text{ for } x \geq 0, \]
where $n$ is $n$ and $x$ is $x$.

Remarks: The effect of calling each of these functions is implementation-defined if $n \geq 128$.

See also 26.8.6.10.

26.9 Numbers

26.9.1 Header <numbers> synopsis

```cpp
namespace std::numbers {
    template<class T> inline constexpr T e_v = unspecified;
    template<class T> inline constexpr T log2e_v = unspecified;
    template<class T> inline constexpr T log10e_v = unspecified;
    template<class T> inline constexpr T pi_v = unspecified;
    template<class T> inline constexpr T inv_pi_v = unspecified;
    template<class T> inline constexpr T inv_sqrtpi_v = unspecified;
    template<class T> inline constexpr T ln2_v = unspecified;
    template<class T> inline constexpr T ln10_v = unspecified;
    template<class T> inline constexpr T sqrt2_v = unspecified;
    template<class T> inline constexpr T sqrt3_v = unspecified;
    template<class T> inline constexpr T inv_sqrt3_v = unspecified;
    template<class T> inline constexpr T egamma_v = unspecified;
    template<class T> inline constexpr T phi_v = unspecified;
}
```

26.9.2 Mathematical constants

The library-defined partial specializations of mathematical constant variable templates are initialized with the nearest representable values of $e$, $\log_2 e$, $\log_{10} e$, $\pi$, $\frac{1}{\sqrt{2}}$, $\ln 2$, $\ln 10$, $\sqrt{2}$, $\sqrt{3}$, $\frac{1}{\sqrt{10}}$, the Euler-Mascheroni $\gamma$ constant, and the golden ratio $\phi$ constant $\frac{1+\sqrt{5}}{2}$, respectively.

Pursuant to 16.5.4.2.1, a program may partially or explicitly specialize a mathematical constant variable template provided that the specialization depends on a program-defined type.

A program that instantiates a primary template of a mathematical constant variable template is ill-formed.
27 Time library

27.1 General

This Clause describes the chrono library (27.2) and various C functions (27.14) that provide generally useful time utilities, as summarized in Table 96.

Table 96: Time library summary

27.3 Cpp17Clock requirements

1 A clock is a bundle consisting of a duration, a time_point, and a function now() to get the current time_point. The origin of the clock’s time_point is referred to as the clock’s epoch. A clock shall meet the requirements in Table 97.

2 In Table 97 C1 and C2 denote clock types. t1 and t2 are values returned by C1::now() where the call returning t1 happens before (6.9.2) the call returning t2 and both of these calls occur before C1::time_point::max(). [Note: This means C1 did not wrap around between t1 and t2. — end note]

<table>

<td>Returns a time_point object representing the current point in time.</td>
</tr>
</tbody>
</table>

3 [Note: The relative difference in durations between those reported by a given clock and the SI definition is a measure of the quality of implementation. — end note]

4 A type TC meets the Cpp17TrivialClock requirements if:

- TC meets the Cpp17Clock requirements (27.3),
- the types TC::rep, TC::duration, and TC::time_point meet the Cpp17EqualityComparable (Table 25) and Cpp17LessThanComparable (Table 26) requirements and the requirements of numeric types (26.2). [Note: This means, in particular, that operations on these types will not throw exceptions. — end note]
- lvalues of the types TC::rep, TC::duration, and TC::time_point are swappable (16.5.3.2),
- the function TC::now() does not throw exceptions, and
- the type TC::time_point::clock meets the Cpp17TrivialClock requirements, recursively.

27.4 Time-related traits

27.4.1 treat_as_floating_point

template<class Rep> struct treat_as_floating_point : is_floating_point<Rep> {
};

1 The duration template uses the treat_as_floating_point trait to help determine if a duration object can be converted to another duration with a different tick period. If treat_as_floating_point_v<Rep> is true, then implicit conversions are allowed among durations. Otherwise, the implicit convertibility depends on the tick periods of the durations. [Note: The intention of this trait is to indicate whether a given class behaves like a floating-point type, and thus allows division of one value by another with acceptable loss of precision. If treat_as_floating_point_v<Rep> is false, Rep will be treated as if it behaved like an integral type for the purpose of these conversions. — end note]

27.4.2 duration_values

```cpp
template<class Rep>
struct duration_values {
    public:
        static constexpr Rep zero() noexcept;
        static constexpr Rep min() noexcept;
        static constexpr Rep max() noexcept;
};
```

1. The duration template uses the duration_values trait to construct special values of the duration’s representation (Rep). This is done because the representation might be a class type with behavior which requires some other implementation to return these special values. In that case, the author of that class type should specialize duration_values to return the indicated values.

2. ```cpp
static constexpr Rep zero() noexcept;
```

3. ```cpp
Returns: Rep(0). [Note: Rep(0) is specified instead of Rep() because Rep() may have some other meaning, such as an uninitialized value. — end note]
```

4. ```cpp
static constexpr Rep min() noexcept;
```

5. ```cpp
Returns: numeric_limits<Rep>::lowest().
```

6. ```cpp
static constexpr Rep max() noexcept;
```

7. ```cpp
Returns: The value returned shall compare greater than zero().
```

27.4.3 Specializations of common_type

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>> {
    using type = chrono::duration<common_type_t<Rep1, Rep2>, see below>;
};
```

1. The period of the duration indicated by this specialization of common_type is the greatest common divisor of Period1 and Period2. [Note: This can be computed by forming a ratio of the greatest common divisor of Period1::num and Period2::num and the least common multiple of Period1::den and Period2::den. — end note]

2. ```cpp
[Note: The typedef name type is a synonym for the duration with the largest tick period possible where both duration arguments will convert to it without requiring a division operation. The representation of this type is intended to be able to hold any value resulting from this conversion with no truncation error, although floating-point durations may have round-off errors. — end note]
```

```cpp
template<class Clock, class Duration1, class Duration2>
struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>> {
    using type = chrono::time_point<Clock, common_type_t<Duration1, Duration2>>;
};
```

3. The common type of two time_point types is a time_point with the same clock as the two types and the common type of their two durations.

27.4.4 Class template is_clock

```cpp
template<class T> struct is_clock;
```

1. is_clock is a Cpp17UnaryTypeTrait (20.15.1) with a base characteristic of true_type if T meets the Cpp17Clock requirements (27.3), otherwise false_type. For the purposes of the specification of this trait, the extent to which an implementation determines that a type cannot meet the Cpp17Clock requirements is unspecified, except that as a minimum a type T shall not qualify as a Cpp17Clock unless it meets all of the following conditions:

   (1) the qualified-ids T::rep, T::period, T::duration, and T::time_point are valid and each denotes a type (13.10.2),
---

1. The expression `T::is_steady` is well-formed when treated as an unevaluated operand.

2. The expression `T::now()` is well-formed when treated as an unevaluated operand.

2 The behavior of a program that adds specializations for `is_clock` is undefined.

### 27.5 Class template duration

A duration type measures time between two points in time (`time_points`). A duration has a representation which holds a count of ticks and a tick period. The tick period is the amount of time which occurs from one tick to the next, in units of seconds. It is expressed as a rational constant using the template `ratio`.

```cpp
namespace std::chrono {
    template<class Rep, class Period = ratio<1>>
    class duration {
        using rep = Rep;
        using period = typename Period::type;

        public:
            constexpr duration() = default;
            template<class Rep2>
            constexpr explicit duration(const Rep2& r);
            template<class Rep2, class Period2>
            constexpr duration(const duration<Rep2, Period2>& d);
            ~duration() = default;
            duration(const duration&) = default;
            duration& operator=(const duration&) = default;

        public:
            constexpr rep count() const;

        public:
            // 27.5.1, construct/copy/destroy
            constexpr duration() = default;
            template<class Rep2>
                constexpr explicit duration(const Rep2& r);
            template<class Rep2, class Period2>
                constexpr duration(const duration<Rep2, Period2>& d);
            ~duration() = default;
            duration(const duration&) = default;
            duration& operator=(const duration&) = default;

            // 27.5.2, observer
            constexpr rep count() const;

        // 27.5.3, arithmetic
            constexpr common_type_t<duration> operator+(const duration& d);
            constexpr common_type_t<duration> operator-(const duration& d);
            constexpr duration& operator+=(const duration& d);
            constexpr duration& operator-=(const duration& d);
            constexpr duration& operator*=(const rep& rhs);
            constexpr duration& operator/=(const rep& rhs);
            constexpr duration& operator%=(const rep& rhs);

            // 27.5.4, special values
            static constexpr duration zero() noexcept;
            static constexpr duration min() noexcept;
            static constexpr duration max() noexcept;
    };
}
```

2 `Rep` shall be an arithmetic type or a class emulating an arithmetic type. If `duration` is instantiated with a `duration` type as the argument for the template parameter `Rep`, the program is ill-formed.

3 If `Period` is not a specialization of `ratio`, the program is ill-formed. If `Period::num` is not positive, the program is ill-formed.

4 Members of `duration` do not throw exceptions other than those thrown by the indicated operations on their representations.
The defaulted copy constructor of duration shall be a constexpr function if and only if the required initialization of
the member rep_ for copy and move, respectively, would satisfy the requirements for a constexpr function.

[Example:

duration<long, ratio<60>> d0; // holds a count of minutes using a long
duration<long long, milli> d1; // holds a count of milliseconds using a long long
duration<double, ratio<1, 30>> d2; // holds a count with a tick period of \frac{1}{30} of a second
   // (30 Hz) using a double
— end example]

27.5.1 Constructors

```cpp
template<class Rep2>
constexpr explicit duration(const Rep2& r);
```

1 Constraints:

- `is_convertible_v<const Rep2&, rep>` is true
- `treat_as_floating_point_v<rep>` is true or
- `treat_as_floating_point_v<Rep2>` is false.

[Example:

duration<int, milli> d(3); // OK
duration<int, milli> d(3.5); // error
— end example]

2 Postconditions: `count() == static_cast<rep>(r)`.

```cpp
template<class Rep2, class Period2>
constexpr duration(const duration<Rep2, Period2>& d);
```

3 Constraints: No overflow is induced in the conversion and `treat_as_floating_point_v<Rep2>` is true or both `ratio_divide<Period2, period>::den` is 1 and `treat_as_floating_point_v<Rep2>` is false.

[Note: This requirement prevents implicit truncation error when converting between integral-based duration types. Such a construction could easily lead to confusion about the value of the duration. — end note]

[Example:

duration<int, milli> ms(3); // OK
duration<int, micro> us = ms; // error
— end example]

4 Effects: Initializes rep_ with `duration_cast<duration>(d).count()`.

27.5.2 Observer

```cpp
constexpr rep count() const;
```

1 Returns: rep_.

27.5.3 Arithmetic

```cpp
constexpr common_type_t<duration> operator+() const;
```

1 Returns: `common_type_t<duration>(*this)`.

```cpp
constexpr common_type_t<duration> operator-() const;
```

2 Returns: `common_type_t<duration>(-rep_)`.

```cpp
constexpr duration& operator++();
```

3 Effects: Equivalent to: `++rep_`

4 Returns: `*this`.

```cpp
constexpr duration operator++(int);
```

5 Effects: Equivalent to: `return duration(rep_++)`
constexpr duration& operator--();

   Effects: Equivalent to: --rep_

   Returns: *this.

constexpr duration operator--(int);

   Effects: Equivalent to: return duration(rep_--);

constexpr duration& operator+=(const duration& d);

   Effects: Equivalent to: rep_ += d.count().

   Returns: *this.

constexpr duration operator-=(const duration& d);

   Effects: Equivalent to: rep_ -= d.count().

   Returns: *this.

constexpr duration& operator*=(const rep& rhs);

   Effects: Equivalent to: rep_ *= rhs

   Returns: *this.

constexpr duration& operator/=(const rep& rhs);

   Effects: Equivalent to: rep_ /= rhs

   Returns: *this.

constexpr duration& operator%=(const rep& rhs);

   Effects: Equivalent to: rep_ %= rhs

   Returns: *this.

constexpr duration& operator%=(const duration& rhs);

   Effects: Equivalent to: rep_ %= rhs.count().

   Returns: *this.

27.5.4 Special values

static constexpr duration zero() noexcept;

   Returns: duration(duration_values<rep>::zero()).

static constexpr duration min() noexcept;

   Returns: duration(duration_values<rep>::min()).

static constexpr duration max() noexcept;

   Returns: duration(duration_values<rep>::max()).

27.5.5 Non-member arithmetic

In the function descriptions that follow, unless stated otherwise, let CD represent the return type of the function.

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

   Returns: CD(CD(lhs).count() + CD(rhs).count()).

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

   Returns: CD(CD(lhs).count() - CD(rhs).count()).
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator*(const duration<Rep1, Period>& d, const Rep2& s);

Constraints: is_convertible_v<const Rep2&, common_type_t<Rep1, Rep2>> is true.

Returns: CD(CD(d).count() * s).

template<class Rep1, class Period>
constexpr duration<common_type_t<Rep1, Rep1>, Period>
operator/(const Rep1& s, const duration<Rep2, Period>& d);

Constraints: is_convertible_v<const Rep1&, common_type_t<Rep1, Rep1>> is true.

Returns: d * s.

template<class Rep1, class Period, class Rep2, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Let CD bc common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>.

Returns: CD(CD(lhs).count() % CD(rhs).count()).

§ 27.5.6 Comparisons

In the function descriptions that follow, CT represents common_type_t<A, B>, where A and B are the types of the two arguments to the function.

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator==(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CT(lhs).count() == CT(rhs).count().

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CT(lhs).count() < CT(rhs).count().

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: rhs < lhs.
template<
class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<=(const duration<Rep1, Period1>& lhs,
const duration<Rep2, Period2>& rhs);

Returns: !(rhs < lhs).

template<
class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>=(const duration<Rep1, Period1>& lhs,
const duration<Rep2, Period2>& rhs);

Returns: !(lhs < rhs).

template<
class Rep1, class Period1, class Rep2, class Period2>
requires three_way_comparable<typename CT::rep>
constexpr auto operator<=>(const duration<Rep1, Period1>& lhs,
const duration<Rep2, Period2>& rhs);

Returns: CT(lhs).count() <=> CT(rhs).count().

27.5.7 Conversions

template<
class ToDuration, class Rep, class Period>
constexpr ToDuration duration_cast(const duration<Rep, Period>& d);

Constraints: ToDuration is a specialization of duration.

Returns: Let CF be ratio divide<Period, typename ToDuration::period>, and CR be common_type<typename
ToDuration::rep, Rep, intmax_t>::type.

(2.1) — If CF::num == 1 and CF::den == 1, returns

ToDuration(static_cast<typename ToDuration::rep>(d.count()))

(2.2) — Otherwise, if CF::num != 1 and CF::den == 1, returns

ToDuration(static_cast<typename ToDuration::rep>(
static_cast<CR>(d.count()) * static_cast<CR>(CF::num)))

(2.3) — Otherwise, if CF::num == 1 and CF::den != 1, returns

ToDuration(static_cast<typename ToDuration::rep>(
static_cast<CR>(d.count()) / static_cast<CR>(CF::den)))

(2.4) — Otherwise, returns

ToDuration(static_cast<typename ToDuration::rep>(
static_cast<CR>(d.count()) * static_cast<CR>(CF::num) / static_cast<CR>(CF::den)))

[Note: This function does not use any implicit conversions; all conversions are done with static_cast.
It avoids multiplications and divisions when it is known at compile time that one or more arguments is 1.
Intermediate computations are carried out in the widest representation and only converted to the destination
representation at the final step. — end note]

template<
class ToDuration, class Rep, class Period>
constexpr ToDuration floor(const duration<Rep, Period>& d);

Constraints: ToDuration is a specialization of duration.

Returns: The greatest result t representable in ToDuration for which t <= d.

template<
class ToDuration, class Rep, class Period>
constexpr ToDuration ceil(const duration<Rep, Period>& d);

Constraints: ToDuration is a specialization of duration.

Returns: The least result t representable in ToDuration for which t >= d.

template<
class ToDuration, class Rep, class Period>
constexpr ToDuration round(const duration<Rep, Period>& d);

Constraints: ToDuration is a specialization of duration and treat_as_floating_point_v<typename
ToDuration::rep> is false.

Returns: The value of ToDuration that is closest to d. If there are two closest values, then return the value t
for which t % 2 == 0.
27.5.8 Suffixes for duration literals

This subclause describes literal suffixes for constructing duration literals. The suffixes h, min, s, ms, us, ns denote duration values of the corresponding types hours, minutes, seconds, milliseconds, microseconds, and nanoseconds respectively if they are applied to integer-literals.

If any of these suffixes are applied to a floating-point-literal the result is a chrono::duration literal with an unspecified floating-point representation.

If any of these suffixes are applied to an integer-literal and the resulting chrono::duration value cannot be represented in the result type because of overflow, the program is ill-formed.

[Example: The following code shows some duration literals.

```cpp
using namespace std::chrono_literals;
auto constexpr aday=24h;
auto constexpr lesson=45min;
auto constexpr halfanhour=0.5h;
```
— end example]

constexpr chrono::hours operator""h(unsigned long long hours);
constexpr chrono::duration<
    unspecified,
ratio<3600, 1>>
operator""h(long double hours);

Returns: A duration literal representing hours.

constexpr chrono::minutes operator""min(unsigned long long minutes);
constexpr chrono::duration<
    unspecified,
ratio<60, 1>>
operator""min(long double minutes);

Returns: A duration literal representing minutes.

constexpr chrono::seconds operator""s(unsigned long long sec);
constexpr chrono::duration<
    unspecified,>
operator""s(long double sec);

Returns: A duration literal representing seconds.

[Note: The same suffix s is used for basic_string but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note]

constexpr chrono::milliseconds operator""ms(unsigned long long msec);
constexpr chrono::duration<
    unspecified, milli>
operator""ms(long double msec);

Returns: A duration literal representing milliseconds.

constexpr chrono::microseconds operator""us(unsigned long long usec);
constexpr chrono::duration<
    unspecified, micro>
operator""us(long double usec);

Returns: A duration literal representing microseconds.

constexpr chrono::nanoseconds operator""ns(unsigned long long nsec);
constexpr chrono::duration<
    unspecified, nano>
operator""ns(long double nsec);

Returns: A duration literal representing nanoseconds.

27.5.9 Algorithms

template<class Rep, class Period>
constexpr duration<Rep, Period> abs(duration<Rep, Period> d);

Constraints: numeric_limits<Rep>::is_signed is true.

Returns: If d >= d.zero(), return d, otherwise return -d.

27.5.10 I/O

template<class charT, class traits, class Rep, class Period>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const duration<Rep, Period>& d);

Effects: Inserts the duration d onto the stream os as if it were implemented as follows:

```cpp
basic_ostringstream<charT, traits> s;
s.flags(os.flags());
s.imbue(os.getloc());
```
s. precision(os. precision());
s << d. count() << units- suffix;
return os << s. str();

where \(\text{units- suffix}\) depends on the type Period:: type as follows:

1. If Period:: type is atto, \(\text{units- suffix}\) is "as".
2. Otherwise, if Period:: type is femto, \(\text{units- suffix}\) is "fs".
3. Otherwise, if Period:: type is pico, \(\text{units- suffix}\) is "ps".
4. Otherwise, if Period:: type is nano, \(\text{units- suffix}\) is "ns".
5. Otherwise, if Period:: type is micro, it is implementation-defined whether \(\text{units- suffix}\) is "\u00b5s" ("\u00b5s") or "us".
6. Otherwise, if Period:: type is milli, \(\text{units- suffix}\) is "ms".
7. Otherwise, if Period:: type is centi, \(\text{units- suffix}\) is "cs".
8. Otherwise, if Period:: type is deci, \(\text{units- suffix}\) is "ds".
9. Otherwise, if Period:: type is ratio<1>, \(\text{units- suffix}\) is "s".
10. Otherwise, if Period:: type is deca, \(\text{units- suffix}\) is "das".
11. Otherwise, if Period:: type is hecto, \(\text{units- suffix}\) is "hs".
12. Otherwise, if Period:: type is kilo, \(\text{units- suffix}\) is "ks".
13. Otherwise, if Period:: type is mega, \(\text{units- suffix}\) is "Ms".
14. Otherwise, if Period:: type is giga, \(\text{units- suffix}\) is "Gs".
15. Otherwise, if Period:: type is tera, \(\text{units- suffix}\) is "Ts".
16. Otherwise, if Period:: type is peta, \(\text{units- suffix}\) is "Ps".
17. Otherwise, if Period:: type is exa, \(\text{units- suffix}\) is "Es".
18. Otherwise, if Period:: type is ratio<60>, \(\text{units- suffix}\) is "min".
19. Otherwise, if Period:: type is ratio<3600>, \(\text{units- suffix}\) is "h".
20. Otherwise, if Period:: type is ratio<86400>, \(\text{units- suffix}\) is "d".
21. Otherwise, if Period:: type::den == 1, \(\text{units- suffix}\) is \(\lbrack\text{num}\rbrack\)s".
22. Otherwise, \(\text{units- suffix}\) is \(\lbrack\text{num}/\text{den}\rbrack\)s".

In the list above, the use of num and den refer to the static data members of Period::type, which are converted to arrays of charT using a decimal conversion with no leading zeroes.

2 Returns: os.

```cpp
template<class charT, class traits, class Rep, class Period, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, duration<Rep, Period>& d, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
```

3 Effects: Attempts to parse the input stream is into the duration d using the format flags given in the NTCTS fmt as specified in 27.13. If the parse parses everything specified by the parsing format flags without error, and yet none of the flags impacts a duration, d will be assigned a zero value. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

4 Returns: is.

§ 27.6 Class template time_point

namespace std::chrono {
    template<class Clock, class Duration = typename Clock::duration>
    class time_point {
    public:
        using clock = Clock;
```
using duration = Duration;
using rep = typename duration::rep;
using period = typename duration::period;

private:
    duration d_; // exposition only

public:
    // 27.6.1, construct
    constexpr time_point(); // has value epoch
    constexpr explicit time_point(const duration& d); // same as time_point() + d
    template<class Duration2>
        constexpr time_point(const time_point<clock, Duration2>& t);

    // 27.6.2, observer
    constexpr duration time_since_epoch() const;

    // 27.6.3, arithmetic
    constexpr time_point& operator++();
    constexpr time_point operator++(int);
    constexpr time_point& operator--();
    constexpr time_point operator--(int);
    constexpr time_point& operator+=(const duration& d);
    constexpr time_point& operator-=(const duration& d);

    // 27.6.4, special values
    static constexpr time_point min() noexcept;
    static constexpr time_point max() noexcept;
);

1 Clock shall either meet the Cpp17Clock requirements (27.3) or be the type local_t.
2 If Duration is not an instance of duration, the program is ill-formed.

27.6.1 Constructors

constexpr time_point();

   Effects: Initializes d_ with duration::zero(). Such a time_point object represents the epoch.

constexpr explicit time_point(const duration& d);

   Effects: Initializes d_ with d. Such a time_point object represents the epoch + d.

template<class Duration2>
    constexpr time_point(const time_point<clock, Duration2>& t);

   Constraints: is_convertible_v<Duration2, duration> is true.
   Effects: Initializes d_ with t.time_since_epoch().

27.6.2 Observer

constexpr duration time_since_epoch() const;

   Returns: d_.

27.6.3 Arithmetic

constexpr time_point& operator++();

   Effects: Equivalent to: ++d_.
   Returns: *this.

constexpr time_point operator++(int);

   Effects: Equivalent to: return time_point{d_++};
constexpr time_point& operator--();
4 Effects: Equivalent to: --d_.
5 Returns: *this.

constexpr time_point operator--(int);
6 Effects: Equivalent to: return time_point{d_--};
7 constexpr time_point& operator+=(const duration& d);
8 Effects: Equivalent to: d_ += d.
9 Returns: *this.
10 constexpr time_point operator-=(const duration& d);
11 Effects: Equivalent to: d_ -= d.
12 Returns: *this.

27.6.4 Special values

static constexpr time_point min() noexcept;
1 Returns: time_point(duration::min()).

static constexpr time_point max() noexcept;
2 Returns: time_point(duration::max()).

27.6.5 Non-member arithmetic

template<class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
operator+(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
1 Returns: CT(lhs.time_since_epoch() + rhs), where CT is the type of the return value.

template<class Rep1, class Period1, class Clock, class Duration2>
constexpr time_point<Clock, common_type_t<duration<Rep1, Period1>, Duration2>>
operator+(const duration<Rep1, Period1>& lhs, const time_point<Clock, Duration2>& rhs);
2 Returns: rhs + lhs.

template<class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>_
operator-(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
3 Returns: CT(lhs.time_since_epoch() - rhs), where CT is the type of the return value.

template<class Clock, class Duration1, class Duration2>
constexpr common_type_t<Duration1, Duration2>
operator-(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
4 Returns: lhs.time_since_epoch() - rhs.time_since_epoch().

27.6.6 Comparisons

template<class Clock, class Duration1, class Duration2>
constexpr bool operator==(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
1 Returns: lhs.time_since_epoch() == rhs.time_since_epoch().

template<class Clock, class Duration1, class Duration2>
constexpr bool operator<(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
2 Returns: lhs.time_since_epoch() < rhs.time_since_epoch().
template<class Clock, class Duration1, class Duration2>
constexpr bool operator>(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: rhs < lhs.

template<class Clock, class Duration1, class Duration2>
constexpr bool operator<=(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: !(rhs < lhs).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator>=(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: !(lhs < rhs).

template<class Clock, class Duration1,
three_way_comparable_with<Duration1> Duration2>
constexpr auto operator<=>(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: lhs.time_since_epoch() <=> rhs.time_since_epoch().

27.6.7 Conversions

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> time_point_cast(const time_point<Clock, Duration>& t);

Constraints: ToDuration is a specialization of duration.

Returns:
time_point<Clock, ToDuration>(duration_cast<ToDuration>(t.time_since_epoch()))

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> floor(const time_point<Clock, Duration>& tp);

Constraints: ToDuration is a specialization of duration.

Returns: time_point<Clock, ToDuration>(floor<ToDuration>(tp.time_since_epoch()))

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> ceil(const time_point<Clock, Duration>& tp);

Constraints: ToDuration is a specialization of duration.

Returns: time_point<Clock, ToDuration>(ceil<ToDuration>(tp.time_since_epoch()))

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> round(const time_point<Clock, Duration>& tp);

Constraints: ToDuration is a specialization of duration, and treat_as_floating_point_v<typename
ToDuration::rep> is false.

Returns: time_point<Clock, ToDuration>(round<ToDuration>(tp.time_since_epoch()))

27.7 Clocks

The types defined in this subclause meet the Cpp17TrivialClock requirements (27.3) unless otherwise specified.

27.7.1 Class system_clock

27.7.1.1 Overview

namespace std::chrono {
class system_clock {
public:
    using rep = see below;
    using period = ratio<unspecified, unspecified>;
    using duration = chrono::duration<rep, period>;
    using time_point = chrono::time_point<system_clock>;
    static constexpr bool is_steady = unspecified;
}
static time_point now() noexcept;

// mapping to/from C type time_t
static time_t to_time_t (const time_point& t) noexcept;
static time_point from_time_t(time_t t) noexcept;
}

Objects of type system_clock represent wall clock time from the system-wide realtime clock. Objects of type sys_time<Duration> measure time since 1970-01-01 00:00:00 UTC excluding leap seconds. This measure is commonly referred to as Unix time. This measure facilitates an efficient mapping between sys_time and calendar types (27.8).

[Example:
sys_seconds(sys_days{1970y/January/1}).time_since_epoch() is 0s.
sys_seconds(sys_days{2000y/January/1}).time_since_epoch() is 946'684'800s, which is 10'957 * 86'400s.
— end example]

27.7.1.2 Members

using system_clock::rep = unspecified;

Constraints: system_clock::duration::min() < system_clock::duration::zero() is true.
[Note: This implies that rep is a signed type. — end note]

static time_t to_time_t(const time_point& t) noexcept;

Returns: A time_t object that represents the same point in time as t when both values are restricted to the coarser of the precisions of time_t and time_point. It is implementation-defined whether values are rounded or truncated to the required precision.

static time_point from_time_t(time_t t) noexcept;

Returns: A time_point object that represents the same point in time as t when both values are restricted to the coarser of the precisions of time_t and time_point. It is implementation-defined whether values are rounded or truncated to the required precision.

27.7.1.3 Non-member functions

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>&& os, const sys_time<Duration>& tp);

Constraints: treat_asFloating_point_v<typename Duration::rep> is false, and Duration{1} < days{1} is true.

Effects: Equivalent to:

auto const dp = floor<days>(tp);
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{} {}"),
year_month_day(dp), hh_mm_ss(tp-dp));

[Example:
cout << sys_seconds(0s) << \n'; // 1970-01-01 00:00:00
cout << sys_seconds(946'684'800s) << \n'; // 2000-01-01 00:00:00
cout << sys_seconds(946'688'523s) << \n'; // 2000-01-01 01:02:03
— end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>&& os, const sys_days& dp);

Effects: os << year_month_day(dp).

Returns: os.

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>&& is, const charT* fmt,
sys_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
6 Effects: Attempts to parse the input stream into the `sys_time tp` using the format flags given in the NTCTS `fmt` as specified in 27.13. If the parse fails to decode a valid date, `is.setstate(ios_base::failbit)` is called and `tp` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to `tp`.

Returns: `is`.

27.7.2 Class `utc_clock` [time.clock.utc]

27.7.2.1 Overview [time.clock.utc.overview]

namespace std::chrono {
    class utc_clock {
        public:
            using rep = a signed arithmetic type;
            using period = ratio<unspecified, unspecified>;
            using duration = chrono::duration<rep, period>;
            using time_point = chrono::time_point<utc_clock>;
            static constexpr bool is_steady = unspecified;

            static time_point now();

            template<class Duration>
                static sys_time<common_type_t<Duration, seconds>>
                    to_sys(const utc_time<Duration>& t);
            template<class Duration>
                static utc_time<common_type_t<Duration, seconds>>
                    from_sys(const sys_time<Duration>& t);
    };
}

1 In contrast to `sys_time`, which does not take leap seconds into account, `utc_clock` and its associated `time_point`, `utc_time`, count time, including leap seconds, since 1970-01-01 00:00:00 UTC. [Note: The UTC time standard began on 1972-01-01 00:00:10 TAI. To measure time since this epoch instead, one can add/subtract the constant `sys_days{1972y/1/1} - sys_days{1970y/1/1} (63's72's000's)` from the `utc_time`. — end note] [Example: `clock_cast<utc_clock>(sys_seconds{sys_days{1970y/January/1}}).time_since_epoch()` is 0s. `clock_cast<utc_clock>(sys_seconds{sys_days{2000y/January/1}}).time_since_epoch()` is 946'684'822s, which is 10'957 * 86'400s + 22s. — end example]

2 `utc_clock` is not a `Cpp17TrivialClock` unless the implementation can guarantee that `utc_clock::now()` does not propagate an exception. [Note: `noexcept(from_sys(system_clock::now()))` is false. — end note]

27.7.2.2 Member functions [time.clock.utc.members]

static time_point now();

template<class Duration>
    static sys_time<common_type_t<Duration, seconds>>
        to_sys(const utc_time<Duration>& t);

2 Returns: A `sys_time t` such that `from_sys(t) == u` if such a mapping exists. Otherwise `u` represents a `time_point` during a positive leap second insertion, the conversion counts that leap second as not inserted, and the last representable value of `sys_time` prior to the insertion of the leap second is returned.

template<class Duration>
    static utc_time<common_type_t<Duration, seconds>>
        from_sys(const sys_time<Duration>& t);

3 Returns: A `utc_time u`, such that `u.time_since_epoch() - t.time_since_epoch()` is equal to the sum of leap seconds that were inserted between `t` and 1970-01-01. If `t` is exactly the date of leap second insertion, then the conversion counts that leap second as inserted.
Example:

```cpp
auto t = sys_days(July/1/2015) - 2ns;
auto u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);
```
— end example

27.7.2.3 Non-member functions

```cpp
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const utc_time<Duration>& t);
```

Effects:

Equivalent to:

```cpp
return os << format("\{:%F %T\}", t);
```

Example:

```cpp
auto t = sys_days(July/1/2015) - 500ms;
auto u = clock_cast<utc_clock>(t);
for (auto i = 0; i < 8; ++i, u += 250ms)
    cout << u << " UTC
```

Produces this output:

```
2015-06-30 23:59:59.500 UTC
2015-06-30 23:59:59.750 UTC
2015-06-30 23:59:60.000 UTC
2015-06-30 23:59:60.250 UTC
2015-06-30 23:59:60.500 UTC
2015-06-30 23:59:60.750 UTC
2015-07-01 00:00:00.000 UTC
2015-07-01 00:00:00.250 UTC
```
— end example

```cpp
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
utc_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);
```

Effects:

Attempts to parse the input stream is into the utc_time tp using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) is called and tp is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns: is.

```cpp
struct leap_second_info {
bool is_leap_second;
seconds elapsed;
};
```

The type `leap_second_info` has data members and special members specified above. It has no base classes or members other than those specified.
template<class Duration>
leap_second_info get_leap_second_info(const utc_time<Duration>& ut);

Returns: A `leap_second_info lsi`, where `lsi.is_leap_second` is true if `ut` is during a positive leap second insertion, and otherwise false. `lsi.elapsed` is the sum of leap seconds between 1970-01-01 and `ut`. If `lsi.is_leap_second` is true, the leap second referred to by `ut` is included in the sum.

27.7.3 Class tai_clock

27.7.3.1 Overview

namespace std::chrono {
  class tai_clock {
    public:
      using rep = a signed arithmetic type;
      using period = ratio<std::ratio<unspecified>, unspecified>;
      using duration = std::chrono::duration<rep, period>;
      using time_point = std::chrono::time_point<tai_clock>;
      static constexpr bool is_steady = unspecified;

      static time_point now();

      template<class Duration>
      static utc_time<common_type_t<Duration, seconds>>
      to_utc(const tai_time<Duration>& t) noexcept;
      template<class Duration>
      static tai_time<common_type_t<Duration, seconds>>
      from_utc(const utc_time<Duration>& t) noexcept;
  };
}

1 The clock `tai_clock` measures seconds since 1958-01-01 00:00:00 and is offset 10s ahead of UTC at this date. That is, 1958-01-01 00:00:00 TAI is equivalent to 1957-12-31 23:59:50 UTC. Leap seconds are not inserted into TAI. Therefore every time a leap second is inserted into UTC, UTC shifts another second with respect to TAI. For example by 2000-01-01 there had been 22 positive and 0 negative leap seconds inserted so 2000-01-01 00:00:00 UTC is equivalent to 2000-01-01 00:00:32 TAI (22s plus the initial 10s offset).

2 `tai_clock` is not a `Cpp17TrivialClock` unless the implementation can guarantee that `tai_clock::now()` does not propagate an exception. [Note: noexcept(from_utc(utc_clock::now())) is false. — end note]

27.7.3.2 Member functions

static time_point now();

Returns: from_utc(utc_clock::now()), or a more accurate value of tai_time.

template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
  to_utc(const tai_time<Duration>& t) noexcept;

Returns:
  utc_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} - 378691210s
  [Note:
    378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s
    — end note]

template<class Duration>
static tai_time<common_type_t<Duration, seconds>>
  from_utc(const utc_time<Duration>& t) noexcept;

Returns:
  tai_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} + 378691210s
  [Note:
    378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s
    — end note]
27.7.3.3  Non-member functions

```cpp
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const tai_time<Duration>& t);
```

1 Effects: Equivalent to:
   ```cpp
   return os << format("{:%F %T}", t);
   ```

2 [Example:]
   ```cpp
   auto st = sys_days{2000y/January/1};
   auto tt = clock_cast<tai_clock>(st);
   cout << format("{0:%F %T %Z} == {1:%F %T %Z}\n", st, tt);
   ```
   Produces this output:
   ```plaintext
   2000-01-01 00:00:00 UTC == 2000-01-01 00:00:32 TAI
   ```
   — end example]

```cpp
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
            tai_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
            minutes* offset = nullptr);
```

3 Effects: Attempts to parse the input stream is into the tai_time tp using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) is called and tp is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

4 Returns: is.

27.7.4  Class gps_clock

27.7.4.1 Overview

```cpp
namespace std::chrono {
    class gps_clock {
        using rep = a signed arithmetic type;
        using period = ratio<unspecified, unspecified>;
        using duration = chrono::duration<rep, period>;
        using time_point = chrono::time_point<gps_clock>;
        static constexpr bool is_steady = unspecified;

        static time_point now();

        template<class Duration>
        static utc_time<common_type_t<Duration, seconds>>
        to_utc(const gps_time<Duration>&) noexcept;
        template<class Duration>
        static gps_time<common_type_t<Duration, seconds>>
        from_utc(const utc_time<Duration>&) noexcept;
    };
}
```

1 The clock gps_clock measures seconds since the first Sunday of January, 1980 00:00:00 UTC. Leap seconds are not inserted into GPS. Therefore every time a leap second is inserted into UTC, UTC shifts another second with respect to GPS. Aside from the offset from 1958y/January/1 to 1980y/January/Sunday[1], GPS is behind TAI by 19s due to the 10s offset between 1958 and 1970 and the additional 9 leap seconds inserted between 1970 and 1980.

2 gps_clock is not a `Cpp17TrivialClock` unless the implementation can guarantee that `gps_clock::now()` does not propagate an exception. [Note: `noexcept(from_utc(utc_clock::now()))` is false. — end note]
27.7.4.2 Member functions

static time_point now();

1

Returns: from_utc(utc_clock::now()), or a more accurate value of gps_time.

template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
to_utc(const gps_time<Duration>& t) noexcept;

2

Returns:
gps_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} + 315964809s

[Note:
315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
— end note]

template<class Duration>
static gps_time<common_type_t<Duration, seconds>>
from_utc(const utc_time<Duration>& t) noexcept;

3

Returns:
gps_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} - 315964809s

[Note:
315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
— end note]

27.7.4.3 Non-member functions

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const gps_time<Duration>& t);

1

Effects: Equivalent to:

return os << format("{{:%F %T}}", t);

2

[Example:

auto st = sys_days{2000y/January/1};
auto gt = clock_cast<gps_clock>(st);
cout << format("{0:%F %T %Z} == {1:%F %T %Z}\n", st, gt);

Produces this output:

2000-01-01 00:00:00 UTC == 2000-01-01 00:00:13 GPS

— end example]

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
gps_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);

3

Effects: Attempts to parse the input stream is into the gps_time tp using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) is called and tp is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

4

Returns: is.

27.7.5 Type file_clock

27.7.5.1 Overview
	namespace std::chrono {
file_clock is an alias for a type meeting the Cpp17TrivialClock requirements (27.3), and using a signed arithmetic type for file_clock::rep. file_clock is used to create the time_point system used for file_time_type (29.11). Its epoch is unspecified, and noexcept(file_clock::now()) is true. [Note: The type that file_clock denotes may be in a different namespace than std::chrono, such as std::filesystem. — end note]

### 27.7.5.2 Member functions

The type denoted by file_clock provides precisely one of the following two sets of static member functions:

```cpp
template<class Duration>
static sys_time<see below>
   to_sys(const file_time<Duration>&);

template<class Duration>
static file_time<see below>
   from_sys(const sys_time<Duration>&);
```

or:

```cpp
template<class Duration>
static utc_time<see below>
   to_utc(const file_time<Duration>&);

template<class Duration>
static file_time<see below>
   from_utc(const utc_time<Duration>&);
```

These member functions shall provide time_point conversions consistent with those specified by utc_clock, tai_clock, and gps_clock. The Duration of the resultant time_point is computed from the Duration of the input time_point.

### 27.7.5.3 Non-member functions

```cpp
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
   operator<<(basic_ostream<charT, traits>& os, const file_time<Duration>& t);
```

**Effects:**

```
return os << format(statically-widen<charT>("{:%F %T}")), t);
```

```cpp
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
   from_stream(basic_istream<charT, traits>& is, const charT* fmt, file_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
```

**Effects:** Attempts to parse the input stream is into the file_time tp using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) is called and tp is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

**Returns:** is.

### 27.7.6 Class steady_clock

```cpp
namespace std::chrono {
   class steady_clock {
      public:
         using rep = unspecified;
         using period = ratio<unspecified, unspecified>;
         using duration = chrono::duration<rep, period>;
         using time_point = chrono::time_point<unspecified, duration>;
         static constexpr bool is_steady = true;
   }
```
27.7.7 Class high_resolution_clock

namespace std::chrono {
    class high_resolution_clock {
    public:
        using rep = unspecified;
        using period = ratio<unspecified, unspecified>;
        using duration = chrono::duration<rep, period>;
        using time_point = chrono::time_point<unspecified, duration>;
        static constexpr bool is_steady = unspecified;

        static time_point now() noexcept;
    };
}

Objects of class high_resolution_clock represent clocks with the shortest tick period.

27.7.8 Local time

The family of time points denoted by local_time<Duration> are based on the pseudo clock local_t. local_t has no member now() and thus does not meet the clock requirements. Nevertheless local_time<Duration> serves the vital role of representing local time with respect to a not-yet-specified time zone. Aside from being able to get the current time, the complete time_point algebra is available for local_time<Duration> (just as for sys_time<Duration>).

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const local_time<Duration>& lt);

Effects:
   os << sys_time<Duration>{lt.time_since_epoch()};

Returns: os.

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
    local_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
    minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the local_time tp using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) is called and tp is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

27.7.9 time_point conversions

27.7.9.1 Class template clock_time_conversion

namespace std::chrono {
    template<class DestClock, class SourceClock>
    struct clock_time_conversion {};
}

clock_time_conversion serves as a trait which can be used to specify how to convert a source time_point of type time_point<SourceClock, Duration> to a destination time_point of type time_point<DestClock,
Duration> via a specialization: clock_time_conversion<DestClock, SourceClock>. A specialization of clock_time_conversion<DestClock, SourceClock> shall provide a const-qualified operator() that takes a parameter of type time_point<SourceClock, Duration> and returns a time_point<DestClock, OtherDuration> representing an equivalent point in time. OtherDuration is a chrono::duration whose specialization is computed from the input Duration in a manner which can vary for each clock_time_conversion specialization. A program may specialize clock_time_conversion if at least one of the template parameters is a user-defined clock type.

2 Several specializations are provided by the implementation, as described in 27.7.9.2, 27.7.9.3, 27.7.9.4, and 27.7.9.5.

27.7.9.2 Identity conversions

```cpp
template<class Clock>
struct clock_time_conversion<Clock, Clock> {
    template<class Duration>
    time_point<Clock, Duration>
    operator()(const time_point<Clock, Duration>& t) const;
};
```

```
template<class Duration>
time_point<Clock, Duration>
operator()(const time_point<Clock, Duration>& t) const;
```

1 Returns: t.

```cpp
template<>
struct clock_time_conversion<system_clock, system_clock> {
    template<class Duration>
sys_time<Duration>
    operator()(const sys_time<Duration>& t) const;
};
```

```
template<class Duration>
sys_time<Duration>
operator()(const sys_time<Duration>& t) const;
```

2 Returns: t.

```cpp
template>
struct clock_time_conversion<utc_clock, utc_clock> {
    template<class Duration>
    utc_time<Duration>
    operator()(const utc_time<Duration>& t) const;
};
```

```
template<class Duration>
utc_time<Duration>
operator()(const utc_time<Duration>& t) const;
```

3 Returns: t.

27.7.9.3 Conversions between system_clock and utc_clock

```cpp
template>
struct clock_time_conversion<utc_clock, system_clock> {
    template<class Duration>
    utc_time<common_type_t<Duration, seconds>>
    operator()(const sys_time<Duration>& t) const;
};
```

```
template<class Duration>
utc_time<common_type_t<Duration, seconds>>
operator()(const sys_time<Duration>& t) const;
```

1 Returns: utc_clock::from_sys(t).

```cpp
template>
struct clock_time_conversion<system_clock, utc_clock> {
    template<class Duration>
    sys_time<common_type_t<Duration, seconds>>
    operator()(const utc_time<Duration>& t) const;
};
```

```
template<class Duration>
sys_time<common_type_t<Duration, seconds>>
operator()(const utc_time<Duration>& t) const;
```
§ 27.7.9.4 Conversions between system_clock and other clocks

```cpp
template<class SourceClock>
struct clock_time_conversion<system_clock, SourceClock> {
    template<class Duration>
    auto operator()(const time_point<SourceClock, Duration>& t) const
    -> decltype(SourceClock::to_sys(t));
};
```

2

```
Returns: SourceClock::to_sys(t).
```

```cpp
template<class DestClock>
struct clock_time_conversion<DestClock, system_clock> {
    template<class Duration>
    auto operator()(const sys_time<Duration>& t) const
    -> decltype(DestClock::from_sys(t));
};
```

1

```
Constraints: SourceClock::to_sys(t) is well-formed.
```

2

```
Mandates: SourceClock::to_sys(t) returns a sys_time<Duration>, where Duration is a valid chrono::duration specialization.
```

3

```
Returns: SourceClock::to_sys(t).
```

§ 27.7.9.5 Conversions between utc_clock and other clocks

```cpp
template<class SourceClock>
struct clock_time_conversion<utc_clock, SourceClock> {
    template<class Duration>
    auto operator()(const time_point<SourceClock, Duration>& t) const
    -> decltype(SourceClock::to_utc(t));
};
```

1

```
Constraints: SourceClock::to_utc(t) is well-formed.
```

2

```
Mandates: SourceClock::to_utc(t) returns a utc_time<Duration>, where Duration is a valid chrono::duration specialization.
```

3

```
Returns: SourceClock::to_utc(t).
```

```cpp
template<class DestClock>
struct clock_time_conversion<DestClock, utc_clock> {
    template<class Duration>
    auto operator()(const utc_time<Duration>& t) const
    -> decltype(DestClock::from_utc(t));
};
```

1

```
Constraints: SourceClock::to_utc(t) is well-formed.
```

2

```
Mandates: SourceClock::to_utc(t) returns a utc_time<Duration>, where Duration is a valid chrono::duration specialization.
```

3

```
Returns: SourceClock::to_utc(t).
```

```cpp
```

§ 27.7.9.5 1234
template<class Duration>
    auto operator()(const utc_time<Duration>& t) const
    -> decltype(DestClock::from_utc(t));

Constraints: DestClock::from_utc(t) is well-formed.

Mandates: DestClock::from_utc(t) returns a time_point<DestClock, Duration>, where Duration is a valid chrono::duration specialization.

Returns: DestClock::from_utc(t).

27.7.9.6 Function template clock_cast

template<class DestClock, class SourceClock, class Duration>
    auto clock_cast(const time_point<SourceClock, Duration>& t);

1 Constraints: At least one of the following clock time conversion expressions is well-formed:
   (1.1) clock_time_conversion<DestClock, SourceClock>{}(t)
   (1.2) clock_time_conversion<DestClock, system_clock>{}(clock_time_conversion<system_clock, SourceClock>{}(t))
   (1.3) clock_time_conversion<DestClock, utc_clock>{}(clock_time_conversion<utc_clock, system_clock>{}(clock_time_conversion<system_clock, SourceClock>{}(t)))
   (1.4) clock_time_conversion<DestClock, utc_clock>{}(clock_time_conversion<utc_clock, system_clock>{}(clock_time_conversion<system_clock, SourceClock>{}(t)))
   (1.5) clock_time_conversion<DestClock, system_clock>{}(clock_time_conversion<system_clock, utc_clock>{}(clock_time_conversion<utc_clock, SourceClock>{}(t)))

A clock time conversion expression is considered better than another clock time conversion expression if it involves fewer operator() calls on clock_time_conversion specializations.

Mandates: Among the well-formed clock time conversion expressions from the above list, there is a unique best expression.

Returns: The best well-formed clock time conversion expression in the above list.

27.8 The civil calendar

27.8.1 In general

The types in 27.8 describe the civil (Gregorian) calendar and its relationship to sys_days and local_days.

27.8.2 Class last_spec

namespace std::chrono {
    struct last_spec {
        explicit last_spec() = default;
    };
}

1 The type last_spec is used in conjunction with other calendar types to specify the last in a sequence. For example, depending on context, it can represent the last day of a month, or the last day of the week of a month.

27.8.3 Class day

27.8.3.1 Overview

namespace std::chrono {
    class day {
        unsigned char d_; // exposition only
        public:
            day() = default;
            constexpr explicit day(unsigned d) noexcept;

            constexpr day& operator++() noexcept;
            constexpr day operator++(int) noexcept;
            constexpr day& operator--() noexcept;
            constexpr day operator--(int) noexcept;

            
§ 27.8.3.1 1235
```cpp
constexpr day& operator+=(const days& d) noexcept;
constexpr day& operator-=(const days& d) noexcept;
constexpr explicit operator unsigned() const noexcept;
constexpr bool ok() const noexcept;
};
```

1. `day` represents a day of a month. It normally holds values in the range 1 to 31, but may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into day’s unspecified internal storage. `day` meets the `Cpp17EqualityComparable` (Table 25) and `Cpp17LessThanComparable` (Table 26) requirements, and participates in basic arithmetic with `days` objects, which represent a difference between two day objects.

2. `day` is a trivially copyable and standard-layout class type.

### 27.8.3.2 Member functions

```cpp
constexpr explicit day(unsigned d) noexcept;
```

1. **Effects:** Initializes `d_` with `d`. The value held is unspecified if `d` is not in the range `[0, 255]`.

```cpp
constexpr day& operator++() noexcept;
```

2. **Effects:** `++d_`.

3. **Returns:** `*this`.

```cpp
constexpr day operator++(int) noexcept;
```

4. **Effects:** `++(*this)`.

5. **Returns:** A copy of `*this` as it existed on entry to this member function.

```cpp
constexpr day& operator--() noexcept;
```

6. **Effects:** Equivalent to: `--d_`.

7. **Returns:** `*this`.

```cpp
constexpr day operator--(int) noexcept;
```

8. **Effects:** `--(*this)`.

9. **Returns:** A copy of `*this` as it existed on entry to this member function.

```cpp
constexpr day& operator+=(const days& d) noexcept;
```

10. **Effects:** `*this = *this + d`.

11. **Returns:** `*this`.

```cpp
constexpr day& operator-=(const days& d) noexcept;
```

12. **Effects:** `*this = *this - d`.

13. **Returns:** `*this`.

```cpp
constexpr explicit operator unsigned() const noexcept;
```

14. **Returns:** `d_`.

```cpp
constexpr bool ok() const noexcept;
```

15. **Returns:** `1 <= d_ && d_ <= 31`.

### 27.8.3.3 Non-member functions

```cpp
constexpr bool operator==(const day& x, const day& y) noexcept;
```

1. **Returns:** `unsigned{x} == unsigned{y}`.

```cpp
constexpr strong_ordering operator<=>(const day& x, const day& y) noexcept;
```

2. **Returns:** `unsigned{x} <=> unsigned{y}`.

§ 27.8.3.3
constexpr day operator+(const day& x, const days& y) noexcept;

Returns: day(\text{unsigned\{x\}} + y.\text{count()}).

constexpr day operator+(const days& x, const day& y) noexcept;

Returns: y + x.

constexpr day operator-(const day& x, const days& y) noexcept;

Returns: day\{\text{unsigned\{x\}} - \text{int\{unsigned\{y\}\}}\}.

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const day& d);

Effects: Equivalent to:
\begin{verbatim}
return os << (d.ok() ? 
    format(STATICALLY-WIDEN<charT>("{:%d}\", d) :
    format(STATICALLY-WIDEN<charT>("{:%d} is not a valid day\", d));
\end{verbatim}

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
    day& d, basic_string<charT, traits, Alloc>* abbrev = nullptr,
    minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the day d using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid day, is.setstate(ios_base::failbit) is called and d is not modified. If \%Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If \%z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

constexpr chrono::day operator"d(unsigned long long d) noexcept;

Returns: day\{\text{static\_cast\{unsigned\}}\{d\}}.

27.8.4 Class month

27.8.4.1 Overview

namespace std::chrono {
    class month {
        unsigned char m_; // exposition only
    public:
        month() = default;
        constexpr explicit month(unsigned m) noexcept;

        constexpr month& operator++() noexcept;
        constexpr month operator++(int) noexcept;
        constexpr month& operator--() noexcept;
        constexpr month operator--(int) noexcept;
        
        constexpr month& operator+=(const months& m) noexcept;
        constexpr month& operator-=(const months& m) noexcept;
        
        constexpr explicit operator unsigned() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

\footnote{month represents a month of a year. It normally holds values in the range 1 to 12, but may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into month’s unspecified internal storage. month meets the Cpp17\{EqualityComparable\} (Table 25) and Cpp17\{LessThanComparable\}.
(Table 26) requirements, and participates in basic arithmetic with months objects, which represent a difference between two month objects.

month is a trivially copyable and standard-layout class type.

### 27.8.4.2 Member functions

#### [time.cal.month.members]

```cpp
constexpr explicit month(unsigned m) noexcept;
```

**Effects:** Initializes `m_` with `m`. The value held is unspecified if `m` is not in the range `[0, 255]`.

```cpp
constexpr month& operator++() noexcept;
```

**Effects:** `*this += months{1}`.

**Returns:** `*this`.

```cpp
constexpr month operator++(int) noexcept;
```

**Effects:** `++(*this)`.

**Returns:** A copy of `*this` as it existed on entry to this member function.

```cpp
constexpr month& operator--() noexcept;
```

**Effects:** `*this -= months{1}`.

**Returns:** `*this`.

```cpp
constexpr month operator--(int) noexcept;
```

**Effects:** `--(*this)`.

**Returns:** A copy of `*this` as it existed on entry to this member function.

```cpp
constexpr month& operator+=(const months& m) noexcept;
```

**Effects:** `*this = *this + m`.

**Returns:** `*this`.

```cpp
constexpr month& operator-=(const months& m) noexcept;
```

**Effects:** `*this = *this - m`.

**Returns:** `*this`.

```cpp
constexpr explicit operator unsigned() const noexcept;
```

**Returns:** `m_`.

```cpp
constexpr bool ok() const noexcept;
```

**Returns:** `1 <= m_ && m_ <= 12`.

#### [time.cal.month.nonmembers]

```cpp
constexpr bool operator==(const month& x, const month& y) noexcept;
```

**Returns:** `unsigned{x} == unsigned{y}`.

```cpp
constexpr strong_ordering operator<=>(const month& x, const month& y) noexcept;
```

**Returns:** `unsigned{x} <=> unsigned{y}`.

```cpp
constexpr month operator+(const month& x, const months& y) noexcept;
```

**Returns:** `month{modulo(static_cast<long long>(unsigned{x}) + (y.count() - 1), 12) + 1}`

where `modulo(n, 12)` computes the remainder of `n` divided by 12 using Euclidean division. [Note: Given a divisor of 12, Euclidean division truncates towards negative infinity and always produces a remainder in the range of `[0, 11]`. Assuming no overflow in the signed summation, this operation results in a month holding a value in the range `[1, 12]` even if `!x.ok()`. — end note]  [Example: February + months{11} == January. — end example]
constexpr month operator+(const months& x, const month& y) noexcept;

Returns: y + x.

constexpr month operator-(const month& x, const months& y) noexcept;

Returns: x + -y.

constexpr months operator-(const month& x, const month& y) noexcept;

Returns: If x.ok() == true and y.ok() == true, returns a value m in the range [months{0}, months{11}] satisfying y + m == x. Otherwise the value returned is unspecified. [Example: January - February == months{11}. - end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month& m);

Effects: Equivalent to:
return os << (m.ok() ?
    format(os.getloc(), STATICALLY_WIDEN<charT>("{:%b}"), m):
    format(os.getloc(), STATICALLY_WIDEN<charT>("{} is not a valid month"),
        static_cast<unsigned>(m));

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
    month& m, basic_string<charT, traits, Alloc>* abbrev = nullptr,
    minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the month m using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid month, is.setstate(ios_base::failbit) is called and m is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

27.8.5 Class year

27.8.5.1 Overview

namespace std::chrono {
    class year {
        short y_; // exposition only
    public:
        year() = default;
        constexpr explicit year(int y) noexcept;

        constexpr year& operator++() noexcept;
        constexpr year operator++(int) noexcept;
        constexpr year& operator--() noexcept;
        constexpr year operator--(int) noexcept;

        constexpr year& operator+=(const years& y) noexcept;
        constexpr year& operator-=(const years& y) noexcept;

        constexpr year operator+() const noexcept;
        constexpr year operator-() const noexcept;

        constexpr bool is_leap() const noexcept;

        constexpr explicit operator int() const noexcept;
        constexpr bool ok() const noexcept;

        static constexpr year min() noexcept;
        static constexpr year max() noexcept;
    }
year represents a year in the civil calendar. It can represent values in the range \([\text{min()}, \text{max()}]\). It can be constructed with any int value, which will be subsequently truncated to fit into year’s unspecified internal storage. year meets the \texttt{Cpp17EqualityComparable} (Table 25) and \texttt{Cpp17LessThanComparable} (Table 26) requirements, and participates in basic arithmetic with years objects, which represent a difference between two year objects.

\section*{27.8.5.2 Member functions} \hfill (time.cal.year.members)

\begin{verbatim}
constexpr explicit year(int y) noexcept;
  \textit{Effects}: Initializes \(y_\) with \(y\). The value held is unspecified if \(y\) is not in the range \([-32767, 32767]\).

constexpr year& operator++() noexcept;
  \textit{Effects}: ++\(y_\).
  \textit{Returns}: \*\this.

constexpr year operator++(int) noexcept;
  \textit{Effects}: ++(\this).
  \textit{Returns}: A copy of \*\this as it existed on entry to this member function.

constexpr year& operator--() noexcept;

  minutes* offset = nullptr);
  // Effects: Attempts to parse the input stream is into the year y using the format flags
given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid year, is.setstate(ios_base::failbit) is called
and y is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev
is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset
if offset is non-null.

Returns: is.

constexpr chrono::year operator""y(unsigned long long y) noexcept;
  // Returns: year{static_cast<int>(y)}.

27.8.6  Class weekday

27.8.6.1  Overview

namespace std::chrono {
  class weekday {
  public:
    weekday() = default;
    constexpr explicit weekday(unsigned wd) noexcept;
    constexpr weekday(const sys_days& dp) noexcept;
    constexpr explicit weekday(const local_days& dp) noexcept;

    constexpr weekday& operator++() noexcept;
    constexpr weekday operator++(int) noexcept;
  }
}
constexpr weekday& operator--() noexcept;
constexpr weekday operator--(int) noexcept;
constexpr weekday& operator+=(const days& d) noexcept;
constexpr weekday& operator-=(const days& d) noexcept;
constexpr unsigned c_encoding() const noexcept;
constexpr unsigned iso_encoding() const noexcept;
constexpr bool ok() const noexcept;
constexpr weekday_indexed operator[](unsigned index) const noexcept;
constexpr weekday_last operator[](last_spec) const noexcept;
};

weekday represents a day of the week in the civil calendar. It normally holds values in the range 0 to 6, corresponding to Sunday through Saturday, but it may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into weekday’s unspeciﬁed internal storage. weekday meets the Cpp17EqualityComparable (Table 25) requirements. [Note: weekday is not Cpp17LessThanComparable because there is no universal consensus on which day is the ﬁrst day of the week. weekday’s arithmetic operations treat the days of the week as a circular range, with no beginning and no end. — end note]

weekday is a trivially copyable and standard-layout class type.

27.8.6.2 Member functions

constexpr explicit weekday(unsigned wd) noexcept;

1 Effects: Initializes wd_ with wd == 7 ? 0 : wd. The value held is unspeciﬁed if wd is not in the range [0, 255].

constexpr weekday(const sys_days& dp) noexcept;

2 Effects: Computes what day of the week corresponds to the sys_days dp, and initializes that day of the week in wd_.

3 [Example: If dp represents 1970-01-01, the constructed weekday represents Thursday by storing 4 in wd_. — end example]

constexpr explicit weekday(const local_days& dp) noexcept;

4 Effects: Computes what day of the week corresponds to the local_days dp, and initializes that day of the week in wd_.

5 Postconditions: The value is identical to that constructed from sys_days{dp.time_since_epoch()}.

constexpr weekday& operator++() noexcept;

6 Effects: *this += days{1}.

7 Returns: *this.

constexpr weekday operator++(int) noexcept;

8 Effects: ++(*this).

9 Returns: A copy of *this as it existed on entry to this member function.

constexpr weekday& operator--() noexcept;

10 Effects: *this -= days{1}.

11 Returns: *this.

constexpr weekday operator--(int) noexcept;

12 Effects: --(*this).

13 Returns: A copy of *this as it existed on entry to this member function.

constexpr weekday& operator+=(const days& d) noexcept;

14 Effects: *this = *this + d.
Returns: *this.

constexpr weekday operator-=(const days& d) noexcept;

Effects: *this = *this - d.

Returns: *this.

constexpr unsigned c_encoding() const noexcept;

Returns: wd_.

constexpr unsigned iso_encoding() const noexcept;

Returns: wd_ == 0u ? 7u : wd_.

constexpr bool ok() const noexcept;

Returns: wd_ <= 6.

constexpr weekday_indexed operator[](unsigned index) const noexcept;

Returns: {*this, index}.

constexpr weekday_last operator[](last_spec) const noexcept;

Returns: weekday_last{*this}.

27.8.6.3 Non-member functions

constexpr bool operator==(const weekday& x, const weekday& y) noexcept;

Returns: x.wd_ == y.wd_.

constexpr weekday operator+(const weekday& x, const days& y) noexcept;

Returns:
weekday{modulo(static_cast<long long>(x.wd_) + y.count(), 7)}
where modulo(n, 7) computes the remainder of n divided by 7 using Euclidean division. [Note: Given a divisor of 7, Euclidean division truncates towards negative infinity and always produces a remainder in the range of [0, 6]. Assuming no overflow in the signed summation, this operation results in a weekday holding a value in the range [0, 6] even if !x.ok(). — end note] [Example: Monday + days{6} == Sunday. — end example]

constexpr weekday operator+(const days& x, const weekday& y) noexcept;

Returns: y + x.

constexpr weekday operator-(const weekday& x, const days& y) noexcept;

Returns: x + -y.

constexpr days operator-(const weekday& x, const weekday& y) noexcept;

Returns: If x.ok() == true and y.ok() == true, returns a value d in the range [days{0}, days{6}] satisfying y + d == x. Otherwise the value returned is unspecified. [Example: Sunday - Monday == days{6}. — end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const weekday& wd);

Effects: Equivalent to:
return os << (wd.ok() ?
format(os.getloc(), STATICALLY_WIDEN<charT>("{:%a}"), wd) :
format(os.getloc(), STATICALLY_WIDEN<charT>("{} is not a valid weekday"),
static_cast<unsigned>(wd.wd_)));

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
weekday& wd, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the weekday wd using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid weekday, is.setstate(ios_base::failbit) is called and wd is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

27.8.7 Class weekday_indexed

27.8.7.1 Overview

namespace std::chrono {
    class weekday_indexed {
        chrono::weekday wd_; // exposition only
        unsigned char index_; // exposition only

    public:
        weekday_indexed() = default;
        constexpr weekday_indexed(const chrono::weekday& wd, unsigned index) noexcept;

        constexpr chrono::weekday weekday() const noexcept;
        constexpr unsigned index() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

weekday_indexed represents a weekday and a small index in the range 1 to 5. This class is used to represent the first, second, third, fourth, or fifth weekday of a month.

[Note: A weekday_indexed object can be constructed by indexing a weekday with an unsigned. — end note]
[Example:
    constexpr auto wdi = Sunday[2]; // wdi is the second Sunday of an as yet unspecified month
    static_assert(wdi.weekday() == Sunday);
    static_assert(wdi.index() == 2);
    — end example]

weekday_indexed is a trivially copyable and standard-layout class type.

27.8.7.2 Member functions

constexpr weekday_indexed(const chrono::weekday& wd, unsigned index) noexcept;

Effects: Initializes wd_ with wd and index_ with index. The values held are unspecified if !wd.ok() or index is not in the range [0, 7].

Returns: wd_.

constexpr unsigned index() const noexcept;

Returns: index_.

constexpr bool ok() const noexcept;

Returns: wd_.ok() & 1 <= index_ & index_ <= 5.

27.8.7.3 Non-member functions

constexpr bool operator==(const weekday_indexed& x, const weekday_indexed& y) noexcept;

Returns: x.weekday() == y.weekday() && x.index() == y.index().

template<class charT, class traits>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const weekday_indexed& wdi);

Effects: Equivalent to:
```cpp
auto i = wdi.index();
return os << (i >= 1 && i <= 5 ?
    format(os.getloc(), STATICALLY_WIDEN<charT>("{}[[{}]]"), wdi.weekday(), i) :
    format(os.getloc(), STATICALLY_WIDEN<charT>("{}[[{} is not a valid index]]"),
    wdi.weekday(), i));
```

### 27.8.8 Class `weekday_last` [time.cal.wdl]

#### 27.8.8.1 Overview [time.cal.wdl.overview]

```cpp
namespace std::chrono {
    class weekday_last {
    chronos::weekday wd_; // exposition only

    public:
        constexpr explicit weekday_last(const chronos::weekday& wd) noexcept;
        constexpr chronos::weekday weekday() const noexcept;
        constexpr bool ok() const noexcept;
    };
}
```

1. `weekday_last` represents the last weekday of a month.

2. [Note: A `weekday_last` object can be constructed by indexing a `weekday` with `last`. — end note] [Example:
```cpp
constexpr auto wdl = Sunday[last]; // wdl is the last Sunday of an as yet unspecified month
static_assert(wdl.weekday() == Sunday);
— end example]
```

3. `weekday_last` is a trivially copyable and standard-layout class type.

#### 27.8.8.2 Member functions [time.cal.wdlmembers]

```cpp
constexpr explicit weekday_last(const chronos::weekday& wd) noexcept;
```

1. **Effects:** Initializes `wd_` with `wd`.

```cpp
constexpr chronos::weekday weekday() const noexcept;
```

2. **Returns:** `wd_`.

```cpp
constexpr bool ok() const noexcept;
```

3. **Returns:** `wd_.ok()`.

#### 27.8.8.3 Non-member functions [time.cal.wdlnonmembers]

```cpp
constexpr bool operator==(const weekday_last& x, const weekday_last& y) noexcept;
```

1. **Returns:** `x.weekday() == y.weekday()`.

```cpp
template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const weekday_last& wdl);
```

2. **Effects:** Equivalent to:
```cpp
    return os << format(os.getloc(), STATICALLY_WIDEN<charT>("{}[last]"), wdl.weekday());
```

### 27.8.9 Class `month_day` [time.cal.md]

#### 27.8.9.1 Overview [time.cal.md.overview]

```cpp
namespace std::chrono {
    class month_day {
    chronos::month m_; // exposition only
    chronos::day d_; // exposition only

    public:
        month_day() = default;
        constexpr month_day(const chronos::month& m, const chronos::day& d) noexcept;
```
constexpr chrono::month month() const noexcept;
constexpr chrono::day day() const noexcept;
constexpr bool ok() const noexcept;

1. `month_day` represents a specific day of a specific month, but with an unspecified year. `month_day` meets the `Cpp17EqualityComparable` (Table 25) and `Cpp17LessThanComparable` (Table 26) requirements.

2. `month_day` is a trivially copyable and standard-layout class type.

### 27.8.9.2 Member functions

```cpp
constexpr month_day(const chrono::month& m, const chrono::day& d) noexcept;
```

1. **Effects:** Initializes `m_` with `m`, and `d_` with `d`.

2. **Returns:** `m_`.

3. **Returns:** `d_`.

4. **Returns:** If `m_.ok()` is true, `1d <= d_`, and `d_` is less than or equal to the number of days in month `m_`; otherwise returns `false`. When `m_` == February, the number of days is considered to be 29.

### 27.8.9.3 Non-member functions

```cpp
constexpr bool operator==(const month_day& x, const month_day& y) noexcept;
```

1. **Returns:** `x.month() == y.month() && x.day() == y.day()`.

2. **Effects:** Equivalent to:
   ```cpp
   if (auto c = x.month() <=> y.month(); c != 0) return c;
   return x.day() <=> y.day();
   ```

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const month_day& md);
```

3. **Effects:** Equivalent to:
   ```cpp
   return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{}/{}"),
   md.month(), md.day());
   ```

```cpp
template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>& from_stream(basic_istream<charT, traits>& is, const charT* fmt,
   month_day& md, basic_string<charT, traits, Alloc>* abbrev = nullptr,
   minutes* offset = nullptr);
```

4. **Effects:** Attempts to parse the input stream `is` into the `month_day md` using the format flags given in the NTCTS `fmt` as specified in 27.13. If the parse fails to decode a valid `month_day`, `is.setstate(ios_base::failbit)` is called and `md` is not modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

5. **Returns:** `is`.

### 27.8.10 Class month_day_last

```cpp
namespace std::chrono {
    class month_day_last {
        chrono::month m_; // exposition only
    }
}
```
public:
  constexpr explicit month_day_last(const chrono::month& m) noexcept;

  constexpr month month() const noexcept;
  constexpr bool ok() const noexcept;
};

1 month_day_last represents the last day of a month.

2 [Note: A month_day_last object can be constructed using the expression m/last or last/m, where m is an expression of type month. — end note] [Example:
  constexpr auto mdl = February/last;  // mdl is the last day of February of an as yet unspecified year
  static_assert(mdl.month() == February);
  — end example]

3 month_day_last is a trivially copyable and standard-layout class type.

3

constexpr explicit month_day_last(const chrono::month& m) noexcept;

4 Effects: Initializes m_ with m.

4 constexpr month month() const noexcept;

5 Returns: m_.

5 constexpr bool ok() const noexcept;

6 Returns: m_.ok().

6 constexpr bool operator==(const month_day_last& x, const month_day_last& y) noexcept;

7 Returns: x.month() == y.month().

7 constexpr strong_ordering operator<=>(const month_day_last& x, const month_day_last& y) noexcept;

8 Returns: x.month() <=> y.month().

8 template<class charT, class traits>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const month_day_last& mdl);

9 Effects: Equivalent to:
  return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{}/last"), mdl.month());

27.8.11 Class month_weekday

27.8.11.1 Overview

namespace std::chrono {
  class month_weekday {
    chrono::month m_;  // exposition only
    chrono::weekday_indexed wdi_;  // exposition only
  public:
    constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;

    constexpr chrono::month month() const noexcept;
    constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
    constexpr bool ok() const noexcept;
  };

1 month_weekday represents the nth weekday of a month, of an as yet unspecified year. To do this the month_weekday stores a month and a weekday_indexed.

2 [Example:
  constexpr auto mwd = February/Tuesday[3];  // mwd is the third Tuesday of February of an as yet unspecified year
  static_assert(mwd.month() == February);
  static_assert(mwd.weekday_indexed() == Tuesday[3]);

§ 27.8.11.1 1247
27.8.11.2 Member functions

```cpp
constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;
```

**Effects:** Initializes \(m_\) with \(m\), and \(wdi_\) with \(wdi\).

```cpp
constexpr chrono::month month() const noexcept;
```

**Returns:** \(m_\).

```cpp
constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
```

**Returns:** \(wdi_\).

```cpp
constexpr bool ok() const noexcept;
```

**Returns:** \(m_.ok() \&\& wdi_.ok()\).

27.8.11.3 Non-member functions

```cpp
constexpr bool operator==(const month_weekday& x, const month_weekday& y) noexcept;
```

**Returns:** \(x.month() == y.month() \&\& x.weekday_indexed() == y.weekday_indexed()\).

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const month_weekday& mwd);
```

**Effects:** Equivalent to:

```cpp
return os << format(os.getloc(), "STATICALLY-WIDEN<charT>("/{}/"),
                    mwd.month(), mwd.weekday_indexed());
```

27.8.12 Class month_weekday_last

27.8.12.1 Overview

```cpp
namespace std::chrono {
    class month_weekday_last {
        chrono::month m_; // exposition only
        chrono::weekday_last wdl_; // exposition only
    public:
        constexpr month_weekday_last(const chrono::month& m,
                                      const chrono::weekday_last& wdl) noexcept;

        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday_last weekday_last() const noexcept;
        constexpr bool ok() const noexcept;
    };
}
```

1 month_weekday_last represents the last weekday of a month, of an as yet unspecified year. To do this the month_-
weekday_last stores a month and a weekday_last.

2 [Example:

```cpp
constexpr auto mwd
    = February/Tuesday[last]; // mwd is the last Tuesday of February of an as yet unspecified year
static_assert(mwd.month() == February);
static_assert(mwd.weekday_last() == Tuesday[last]);
```

— end example]

3 month_weekday_last is a trivially copyable and standard-layout class type.

27.8.12.2 Member functions

```cpp
constexpr month_weekday_last(const chrono::month& m,
                               const chrono::weekday_last& wdl) noexcept;
```

**Effects:** Initializes \(m_\) with \(m\), and \(wdl_\) with \(wdl\).
constexpr chrono::month month() const noexcept;

Returns: \(m_{-}\).

constexpr chrono::weekday_last weekday_last() const noexcept;

Returns: \(wdl_{-}\).

constexpr bool ok() const noexcept;

Returns: \(m_{-}.ok() \&\& wdl_{-}.ok()\).

### 27.8.12.3 Non-member functions

constexpr bool operator==(const month_weekday_last& x, const month_weekday_last& y) noexcept;

Returns: \(x.month() == y.month() \&\& x.weekday_last() == y.weekday_last()\).

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month_weekday_last& mwdl);
```

Effects: Equivalent to:

```
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("/{}/"),
                    mwdl.month(), mwdl.weekday_last());
```

### 27.8.13 Class year_month

#### 27.8.13.1 Overview

namespace std::chrono {

class year_month {

chrono::year y_; // exposition only
chrono::month m_; // exposition only

public:

year_month() = default;
constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;

constexpr chrono::year year() const noexcept;

Returns: \(y_{-}\).

constexpr chrono::month month() const noexcept;

Returns: \(m_{-}\).

constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;

Effects: Initializes \(y_{-}\) with \(y\), and \(m_{-}\) with \(m\).

constexpr chrono::year year() const noexcept;

Returns: \(y_{-}\).

constexpr chrono::month month() const noexcept;

Returns: \(m_{-}\).

1 year_month represents a specific month of a specific year, but with an unspecified day. year_month is a field-based time point with a resolution of months. year_month meets the Cpp17EqualityComparable (Table 25) and Cpp17LessThanComparable (Table 26) requirements.

2 year_month is a trivially copyable and standard-layout class type.
constexpr year_month& operator+=(const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Effects: *this = *this + dm.

Returns: *this.

constexpr year_month& operator-=(const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Effects: *this = *this - dm.

Returns: *this.

constexpr year_month& operator+=(const years& dy) noexcept;

Effects: *this = *this + dy.

Returns: *this.

constexpr year_month& operator-=(const years& dy) noexcept;

Effects: *this = *this - dy.

Returns: *this.

constexpr bool ok() const noexcept;

Returns: y_.ok() && m_.ok().

27.8.13.3 Non-member functions

constexpr bool operator==(const year_month& x, const year_month& y) noexcept;

Returns: x.year() == y.year() && x.month() == y.month().

constexpr strong_ordering operator<=>(const year_month& x, const year_month& y) noexcept;

Effects: Equivalent to:
if (auto c = x.year() <=> y.year(); c != 0) return c;
return x.month() <=> y.month();

constexpr year_month operator+(const year_month& ym, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: A year_month value z such that z.ok() && z - ym == dm is true.
Complexity: \( O(1) \) with respect to the value of dm.

constexpr year_month operator+(const months& dm, const year_month& ym) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: ym + dm.

constexpr year_month operator-(const year_month& ym, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: ym + -dm.

constexpr months operator-(const year_month& x, const year_month& y) noexcept;

Returns:
\[ x . year () - y . year () + \text{months}\{\text{static\_cast<int>\{\text{unsigned\{x.month\()\}\}}\} - \text{static\_cast<int>\{\text{unsigned\{y.month\()\}}\}} \]
constexpr year_month operator+(const year_month& ym, const years& dy) noexcept;

Returns: (ym.year() + dy) / ym.month().

cstexpr year_month operator+(const years& dy, const year_month& ym) noexcept;

Returns: ym + dy.

cstexpr year_month operator-(const year_month& ym, const years& dy) noexcept;

Returns: ym + -dy.

template<class charT, class traits>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const year_month& ym);

Effects: Equivalent to:
  
  return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{}/{}"),
   ym.year(), ym.month());

template<class charT, class traits, class Alloc = allocator<charT>>
  basic_istream<charT, traits>&
  from_stream(basic_istream<charT, traits>& is, const charT* fmt,
   year_month& ym, basic_string<charT, traits, Alloc>* abbrev = nullptr,
   minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the year_month ym using the format flags given in the NTCTS fmt as specified in 27.13. If the parse fails to decode a valid year_month, is.setstate(ios_base::failbit) is called and ym is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

27.8.14 Class year_month_day

27.8.14.1 Overview

namespace std::chrono {

class year_month_day {
  chrono::year y_;  // exposition only
  chrono::month m_;  // exposition only
  chrono::day d_;    // exposition only

public:
  year_month_day() = default;
  constexpr year_month_day(const chrono::year& y, const chrono::month& m,
   const chrono::day& d) noexcept;
  constexpr year_month_day(const year_month_day_last& ymdl) noexcept;
  constexpr year_month_day(const sys_days& dp) noexcept;
  constexpr explicit year_month_day(const local_days& dp) noexcept;

  constexpr year_month_day& operator+=(const months& m) noexcept;
  constexpr year_month_day& operator-=(const months& m) noexcept;
  constexpr year_month_day& operator+=(const years& y) noexcept;
  constexpr year_month_day& operator-=(const years& y) noexcept;

  constexpr chrono::year year() const noexcept;
  constexpr chrono::month month() const noexcept;
  constexpr chrono::day day() const noexcept;

  constexpr operator sys_days() const noexcept;
  constexpr explicit operator local_days() const noexcept;
  constexpr bool ok() const noexcept;
};

1 year_month_day represents a specific year, month, and day. year_month_day is a field-based time point with a resolution of days. [Note: year_month_day supports years- and months-oriented arithmetic, but not days-oriented arithmetic. —END NOTE]
year_month_day has a conversion to sys_days, which efficiently supports days-oriented arithmetic.

27.8.14.2 Member functions

```cpp
constexpr year_month_day(const chrono::year& y, const chrono::month& m, const chrono::day& d) noexcept;
    Effects: Initializes y_ with y, m_ with m, and d_ with d.

cconstexpr year_month_day(const year_month_day_last& ymdl) noexcept;
    Effects: Initializes y_ with ymdl.year(), m_ with ymdl.month(), and d_ with ymdl.day().
    [Note: This conversion from year_month_day_last to year_month_day may be more efficient than converting a year_month_day_last to a sys_days, and then converting that sys_days to a year_month_day. — end note]

cconstexpr year_month_day(const sys_days& dp) noexcept;
    Effects: Constructs an object of type year_month_day that corresponds to the date represented by dp.

Remarks: For any value ymd of type year_month_day for which ymd.ok() is true, ymd == year_month_day{sys_days{ymd}} is true.

cconstexpr explicit year_month_day(const local_days& dp) noexcept;
    Effects: Equivalent to constructing with sys_days{dp.time_since_epoch()}.

cconstexpr year_month_day& operator+=(const months& m) noexcept;
    Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).
    Effects: *this = *this + m.

Returns: *this.

cconstexpr year_month_day& operator-=(const months& m) noexcept;
    Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).
    Effects: *this = *this - m.

Returns: *this.

cconstexpr year_month_day& year_month_day::operator+=(const years& y) noexcept;
    Effects: *this = *this + y.

Returns: *this.

cconstexpr year_month_day& year_month_day::operator-=(const years& y) noexcept;
    Effects: *this = *this - y.

Returns: *this.

constexpr chrono::year year() const noexcept;
    Returns: y_.

cconstexpr chrono::month month() const noexcept;
    Returns: m_.

cconstexpr chrono::day day() const noexcept;
    Returns: d_.
```

Dxxxx

arithmetic. For the latter, there is a conversion to sys_days, which efficiently supports days-oriented arithmetic.

— end note] year_month_day meets the Cpp17EqualityComparable (Table 25) and Cpp17LessThanComparable (Table 26) requirements.

2 year_month_day is a trivially copyable and standard-layout class type.
constexpr operator sys_days() const noexcept;

Returns: If ok(), returns a sys_days holding a count of days from the sys_days epoch to *this (a negative value if *this represents a date prior to the sys_days epoch). Otherwise, if y_.ok() && m_.ok() is true, returns sys_days(y_/m_/1d) + (d_ - 1d). Otherwise the value returned is unspecified.

Remarks: A sys_days in the range [days{-12687428}, days{11248737}] which is converted to a year_month_day has the same value when converted back to a sys_days.

[Example:
static_assert(year_month_day{sys_days{2017y/January/0}} == 2016y/December/31);
static_assert(year_month_day{sys_days{2017y/January/31}} == 2017y/January/31);
static_assert(year_month_day{sys_days{2017y/January/32}} == 2017y/February/1);
— end example]

constexpr explicit operator local_days() const noexcept;

Returns: local_days{sys_days{*this}.time_since_epoch()}.

constexpr bool ok() const noexcept;

Returns: If y_.ok() is true, and m_.ok() is true, and d_ is in the range [1d, (y_/m_/last).day()], then returns true; otherwise returns false.

27.8.14.3 Non-member functions [time.cal.ymd.nonmembers]

constexpr bool operator==(const year_month_day& x, const year_month_day& y) noexcept;

Returns: x.year() == y.year() && x.month() == y.month() && x.day() == y.day().

constexpr strong_ordering operator<=>(const year_month_day& x, const year_month_day& y) noexcept;

Effects: Equivalent to:
if (auto c = x.year() <=> y.year(); c != 0) return c;
if (auto c = x.month() <=> y.month(); c != 0) return c;
return x.day() <=> y.day();

constexpr year_month_day operator+(const year_month_day& ymd, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: (ymd.year() / ymd.month() + dm) / ymd.day().

[Note: If ymd.day() is in the range [1d, 28d], ok() will return true for the resultant year_month_day. — end note]

constexpr year_month_day operator+(const months& dm, const year_month_day& ymd) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: ymd + dm.

constexpr year_month_day operator-(const year_month_day& ymd, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: ymd + (-dm).

constexpr year_month_day operator+(const year_month_day& ymd, const years& dy) noexcept;

Returns: (ymd.year() + dy) / ymd.month() / ymd.day().

[Note: If ymd.month() is February and ymd.day() is not in the range [1d, 28d], ok() may return false for the resultant year_month_day. — end note]

constexpr year_month_day operator+(const years& dy, const year_month_day& ymd) noexcept;

Returns: ymd + dy.
constexpr year_month_day operator-(const year_month_day& ymd, const years& dy) noexcept;

Returns: ymd + (-dy).

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year_month_day& ymd);

Effects: Equivalent to:
return os << (ymd.ok() ?
    format(STATICALLY-WIDEN<charT>"{%F}", ymd) :
    format(STATICALLY-WIDEN<charT>"{%F} is not a valid date"), ymd));

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
    year_month_day& ymd, basic_string<charT, traits, Alloc>* abbrev = nullptr,
    minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the year_month_day ymd using the format flags given in the
NTCTS fmt as specified in 27.13. If the parse fails to decode a valid year_month_day, is.setstate(ios_base::failbit) is
called and ymd is not modified. If %Z is used and successfully parsed, that value will be
assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that
value will be assigned to *offset if offset is non-null.

Returns: is.

27.8.15 Class year_month_day_last

27.8.15.1 Overview

namespace std::chrono {
    class year_month_day_last {
        // exposition only
        chrono::year y_;  // exposition only
        chrono::month_day_last mdl_;  // exposition only

        public:
            constexpr year_month_day_last(const chrono::year& y,
                const chrono::month_day_last& mdl) noexcept;

            constexpr year_month_day_last& operator+=(const months& m) noexcept;
            constexpr year_month_day_last& operator-=(const months& m) noexcept;
            constexpr year_month_day_last& operator+=(const years& y) noexcept;
            constexpr year_month_day_last& operator-=(const years& y) noexcept;

            constexpr chrono::year year() const noexcept;
            constexpr chrono::month month() const noexcept;
            constexpr chrono::month_day_last month_day_last() const noexcept;
            constexpr chrono::day day() const noexcept;

            constexpr operator sys_days() const noexcept;
            constexpr explicit operator local_days() const noexcept;
            constexpr bool ok() const noexcept;
    }
};

1 year_month_day_last represents the last day of a specific year and month. year_month_day_last is a field-based
time point with a resolution of days, except that it is restricted to pointing to the last day of a year and month.
[Note: year_month_day_last supports years- and months-oriented arithmetic, but not days-oriented arithmetic.
For the latter, there is a conversion to sys_days, which efficiently supports days-oriented arithmetic. — end note]
year_month_day_last meets the Cpp17EqualityComparable (Table 25) and Cpp17LessThanComparable (Table 26)
requirements.

2 year_month_day_last is a trivially copyable and standard-layout class type.
27.8.15.2 Member functions

```cpp
constexpr year_month_day_last(const chrono::year& y,
const chrono::month_day_last& mdl) noexcept;
```

**Effects:** Initializes `y_` with `y` and `mdl_` with `mdl`.

```cpp
constexpr year_month_day_last& operator+=(const months& m) noexcept;
```

**Constraints:** If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.4.3.2).

**Effects:** `*this = *this + m`.

**Returns:** `*this`.

```cpp
constexpr year_month_day_last& operator-=(const months& m) noexcept;
```

**Constraints:** If the argument supplied by the caller for the `months` parameter is convertible to `years`, its implicit conversion sequence to `years` is worse than its implicit conversion sequence to `months` (12.4.3.2).

**Effects:** `*this = *this - m`.

**Returns:** `*this`.

```cpp
constexpr year_month_day_last& operator+=(const years& y) noexcept;
```

**Effects:** `*this = *this + y`.

**Returns:** `*this`.

```cpp
constexpr year_month_day_last& operator-=(const years& y) noexcept;
```

**Effects:** `*this = *this - y`.

**Returns:** `*this`.

```cpp
constexpr chrono::year year() const noexcept;
```

**Returns:** `y_`.

```cpp
constexpr chrono::month month() const noexcept;
```

**Returns:** `mdl_.month()`.

```cpp
constexpr chrono::month_day_last month_day_last() const noexcept;
```

**Returns:** `mdl_`.

```cpp
constexpr chrono::day day() const noexcept;
```

**Returns:** If `ok()` is true, returns a day representing the last day of the (`year`, `month`) pair represented by `*this`. Otherwise, the returned value is unspecified.

**[Note:** This value may be computed on demand. — end note]**

```cpp
constexpr operator sys_days() const noexcept;
```

**Returns:** `sys_days{year()/month()/day()}`.

```cpp
constexpr explicit operator local_days() const noexcept;
```

**Returns:** `local_days{sys_days{*this}.time_since_epoch()}`.

```cpp
constexpr bool ok() const noexcept;
```

**Returns:** `y_.ok() && mdl_.ok()`.

27.8.15.3 Non-member functions

```cpp
constexpr bool operator==(const year_month_day_last& x, const year_month_day_last& y) noexcept;
```

**Returns:** `x.year() == y.year() && x.month_day_last() == y.month_day_last()`.

```cpp
constexpr strong_ordering operator<=>(const year_month_day_last& x,
const year_month_day_last& y) noexcept;
```

**Effects:** Equivalent to:

§ 27.8.15.3
```cpp
if (auto c = x.year() <=> y.year(); c != 0) return c;
return x.month_day_last() <=> y.month_day_last();

constexpr year_month_day_last
operator+(const year_month_day_last& ymdl, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: (ymdl.year() / ymdl.month() + dm) / last.

constexpr year_month_day_last
operator+(const months& dm, const year_month_day_last& ymdl) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: ymdl + dm.

constexpr year_month_day_last
operator+(const year_month_day_last& ymdl, const months& dm) noexcept;

Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: ymdl + (-dm).

constexpr year_month_day_last
operator+(const year_month_day_last& ymdl, const years& dy) noexcept;

Constraints: If the argument supplied by the caller for the years parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

Returns: ymdl + dy.

constexpr year_month_day_last
operator+(const years& dy, const year_month_day_last& ymdl) noexcept;

Returns: ymdl + dy.

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year_month_day_last& ymdl);

Effects: Equivalent to:

return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{}/{} ",
 ymdl.year(), ymdl.month_day_last());
```

### 27.8.16 Class `year_month_weekday`

#### 27.8.16.1 Overview

```cpp
namespace std::chrono {

class year_month_weekday {

  chrono::year y_; // exposition only
  chrono::month m_; // exposition only
  chrono::weekday_indexed wdi_; // exposition only

public:
  year_month_weekday() = default;
  constexpr year_month_weekday(const chrono::year& y, const chrono::month& m,
                              const chrono::weekday_indexed& wdi) noexcept;
  constexpr year_month_weekday(const sys_days& dp) noexcept;
  constexpr explicit year_month_weekday(const local_days& dp) noexcept;

  constexpr year_month_weekday& operator+=(const months& m) noexcept;
  constexpr year_month_weekday& operator-=(const months& m) noexcept;
  constexpr year_month_weekday& operator+=(const years& y) noexcept;
  constexpr year_month_weekday& operator-=(const years& y) noexcept;

  § 27.8.16.1 1256
year_month_weekday represents a specific year, month, and nth weekday of the month. year_month_weekday is a field-based time point with a resolution of days. [Note: year_month_weekday supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to sys_days, which efficiently supports days-oriented arithmetic. — end note] year_month_weekday meets the Cpp17EqualityComparable (Table 25) requirements.

### 27.8.16.2 Member functions

```cpp
constexpr year_month_weekday(const chrono::year& y, const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;
Effects: Initializes y_ with y, m_ with m, and wdi_ with wdi.
```

```cpp
constexpr year_month_weekday(const sys_days& dp) noexcept;
Effects: Constructs an object of type year_month_weekday which corresponds to the date represented by dp.
Remarks: For any value ymd1 of type year_month_weekday for which ymd1.ok() is true, ymd1 == year_month_weekday{sys_days{ymd1}} is true.
```

```cpp
constexpr explicit year_month_weekday(const local_days& dp) noexcept;
Effects: Equivalent to constructing with sys_days{dp.time_since_epoch()}. 
```

```cpp
constexpr year_month_weekday& operator+=(const months& m) noexcept;
Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2). 
Effects: *this = *this + m.
Returns: *this.
```

```cpp
constexpr year_month_weekday& operator-=(const months& m) noexcept;
Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2). 
Effects: *this = *this - m.
Returns: *this.
```

```cpp
constexpr year_month_weekday& operator+=(const years& y) noexcept;
Effects: *this = *this + y.
Returns: *this.
```

```cpp
constexpr year_month_weekday& operator-=(const years& y) noexcept;
Effects: *this = *this - y.
Returns: *this.
```

```cpp
constexpr chrono::year year() const noexcept;
Returns: y_.
```

```cpp
constexpr chrono::month month() const noexcept;
Returns: m_.
```
constexpr chrono::weekday weekday() const noexcept;
    
    Returns: wdi_.weekday().

constexpr unsigned index() const noexcept;
    
    Returns: wdi_.index().

constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
    
    Returns: wdi_.

constexpr operator sys_days() const noexcept;
    
    Returns: If y_.ok() && m_.ok() && wdi_.weekday().ok(), returns a sys_days that represents the date (index() - 1) * 7 days after the first weekday() of year()/month(). If index() is 0 the returned sys_days represents the date 7 days prior to the first weekday() of year()/month(). Otherwise the returned value is unspecified.

constexpr explicit operator local_days() const noexcept;
    
    Returns: local_days{sys_days{*this}.time_since_epoch()}.

constexpr bool ok() const noexcept;
    
    Returns: If any of y_.ok(), m_.ok(), or wdi_.ok() is false, returns false. Otherwise, if *this represents a valid date, returns true. Otherwise, returns false.

27.8.16.3 Non-member functions

constexpr bool operator==(const year_month_weekday& x, const year_month_weekday& y) noexcept;
    
    Returns: x.year() == y.year() && x.month() == y.month() && x.weekday_indexed() == y.weekday_indexed()

constexpr year_month_weekday operator+(const year_month_weekday& ymwd, const months& dm) noexcept;
    
    Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

    Returns: (ymwd.year() / ymwd.month() + dm) / ymwd.weekday_indexed().

constexpr year_month_weekday operator+(const months& dm, const year_month_weekday& ymwd) noexcept;
    
    Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

    Returns: ymwd + dm.

constexpr year_month_weekday operator-(const year_month_weekday& ymwd, const months& dm) noexcept;
    
    Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

    Returns: ymwd + (-dm).

constexpr year_month_weekday operator+(const year_month_weekday& ymwd, const years& dy) noexcept;
    
    Returns: {ymwd.year()+dy, ymwd.month(), ymwd.weekday_indexed()}

constexpr year_month_weekday operator+(const years& dy, const year_month_weekday& ymwd) noexcept;
    
    Returns: ymwd + dy.

constexpr year_month_weekday operator-(const year_month_weekday& ymwd, const years& dy) noexcept;
    
    Returns: ymwd + (-dy).

template<class charT, class traits>
    
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const year_month_weekday& ymwd);
    
    Effects: Equivalent to:
27.8.17 Class year_month_weekday_last

27.8.17.1 Overview

namespace std::chrono {
    class year_month_weekday_last {
        chrono::year y_;  // exposition only
        chrono::month m_;  // exposition only
        chrono::weekday_last wdl_;  // exposition only
    public:
        constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m,
                                           const chrono::weekday_last& wdl) noexcept;
        constexpr year_month_weekday_last& operator+=(const months& m) noexcept;
        constexpr year_month_weekday_last& operator-=(const months& m) noexcept;
        constexpr year_month_weekday_last& operator+=(const years& y) noexcept;
        constexpr year_month_weekday_last& operator-=(const years& y) noexcept;

        constexpr chrono::year year() const noexcept;
        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday weekday() const noexcept;
        constexpr chrono::weekday_last weekday_last() const noexcept;
        constexpr operator sys_days() const noexcept;
        constexpr explicit operator local_days() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

1. year_month_weekday_last represents a specific year, month, and last weekday of the month. year_month_weekday_last is a field-based time point with a resolution of days, except that it is restricted to pointing to the last weekday of a year and month. [Note: year_month_weekday_last supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to sys_days, which efficiently supports days-oriented arithmetic. — end note] year_month_weekday_last meets the Cpp17EqualityComparable (Table 25) requirements.

2. year_month_weekday_last is a trivially copyable and standard-layout class type.

27.8.17.2 Member functions

constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m,
                                  const chrono::weekday_last& wdl) noexcept;

1. Effects: Initializes y_ with y, m_ with m, and wdl_ with wdl.

constexpr year_month_weekday_last& operator+=(const months& m) noexcept;

2. Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

3. Effects: *this = *this + m.

4. Returns: *this.

constexpr year_month_weekday_last& operator-=(const months& m) noexcept;

5. Constraints: If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).

6. Effects: *this = *this - m.

7. Returns: *this.

constexpr year_month_weekday_last& operator+=(const years& y) noexcept;

8. Effects: *this = *this + y.
9    \textbf{Returns:} *this.
10    constexpr year_month_weekday_last\& operator-=(const years\& y) noexcept;
11    \textbf{Effects:} *this = *this - y.
12    \textbf{Returns:} *this.
13    constexpr chrono::year year() const noexcept;
14    \textbf{Returns:} y_.
15    constexpr chrono::month month() const noexcept;
16    \textbf{Returns:} m_.
17    constexpr chrono::weekday weekday() const noexcept;
18    \textbf{Returns:} wdl_.weekday().
19    constexpr chrono::weekday_last weekday_last() const noexcept;
20    \textbf{Returns:} wdl_.
21    constexpr operator sys_days() const noexcept;
22    \textbf{Returns:} If ok() == true, returns a sys_days that represents the last weekday() of year()/month(). Otherwise the returned value is unspecified.
23    constexpr explicit operator local_days() const noexcept;
24    \textbf{Returns:} local_days{sys_days{*this}.time_since_epoch()}.  
25    constexpr bool ok() const noexcept;
26    \textbf{Returns:} y_.ok() \&\& m_.ok() \&\& wdl_.ok().

37         \textbf{Returns:} ymwdl + dm.
38    constexpr year_month_weekday_last
39         operator+(const year_month_weekday_last\& ymwdl, const months\& dm) noexcept;
40         \textbf{Constraints:} If the argument supplied by the caller for the months parameter is convertible to years, its implicit conversion sequence to years is worse than its implicit conversion sequence to months (12.4.3.2).
41         \textbf{Returns:} ymwdl + (-dm).
42    constexpr year_month_weekday_last
43         operator+(const year_month_weekday_last\& ymwdl, const years\& dy) noexcept;
44         \textbf{Returns:} (ymwdl.year()+dy, ymwdl.month(), ymwdl.weekday_last()).
constexpr year_month_weekday_last
operator+(const years& dy, const year_month_weekday_last& ymwdl) noexcept;

Returns: ymwdl + dy.

constexpr year_month_weekday_last
operator-(const year_month_weekday_last& ymwdl, const years& dy) noexcept;

Returns: ymwdl + (-dy).

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year_month_weekday_last& ymwdl);

Effects: Equivalent to:
return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{}/{}/{}"), ymwdl.year(), ymwdl.month(), ymwdl.weekday_last());

27.8.18 Conventional syntax operators

A set of overloaded operator/ functions provides a conventional syntax for the creation of civil calendar dates.

[Note: The year, month, and day are accepted in any of the following 3 orders:
 year/month/day
 month/day/year
 day/month/year

Anywhere a day is required, any of the following can also be specified:
 last
 weekday[last]
— end note]

[Note: Partial-date types such as year_month and month_day can be created by not applying the second division operator for any of the three orders. For example:
 year_month ym = 2015y/April;
 month_day md1 = April/4;
 month_day md2 = 4d/April;
— end note]

[Example:
 auto a = 2015/4/4; //a == int(125)
 auto b = 2015y/4/4; //b == year_month_day{year(2015), month(4), day(4)}
 auto c = 2015y/4d/April; //error: no viable operator/ for first /
 auto d = 2015/April/4; //error: no viable operator/ for first /
— end example]

constexpr year_month
operator/(const year& y, const month& m) noexcept;

Returns: {y, m}.

constexpr year_month
operator/(const year& y, int m) noexcept;

Returns: y / month(m).

constexpr month_day
operator/(const month& m, const day& d) noexcept;

Returns: {m, d}.

constexpr month_day
operator/(const month& m, int d) noexcept;

Returns: m / day(d).
constexpr month_day
operator/(int m, const day& d) noexcept;

Returns: month(m) / d.

constexpr month_day
operator/(const day& d, const month& m) noexcept;

Returns: m / d.

constexpr month_day
operator/(const day& d, int m) noexcept;

Returns: month(m) / d.

constexpr month_day_last
operator/(const month& m, last_spec) noexcept;

Returns: month_day_last{m}.

constexpr month_day_last
operator/(int m, last_spec) noexcept;

Returns: month(m) / last.

constexpr month_day_last
operator/(const month& m, const month& m) noexcept;

Returns: m / last.

constexpr month_weekday
operator/(const month& m, const weekday_indexed& wdi) noexcept;

Returns: {m, wdi}.

constexpr month_weekday
operator/(int m, const weekday_indexed& wdi) noexcept;

Returns: month(m) / wdi.

constexpr month_weekday
operator/(const weekday_indexed& wdi, const month& m) noexcept;

Returns: m / wdi.

constexpr month_weekday
operator/(const weekday_indexed& wdi, int m) noexcept;

Returns: month(m) / wdi.

constexpr month_weekday_last
operator/(const month& m, const weekday_last& wdl) noexcept;

Returns: {m, wdl}.

constexpr month_weekday_last
operator/(int m, const weekday_last& wdl) noexcept;

Returns: month(m) / wdl.

constexpr month_weekday_last
operator/(const weekday_last& wdl, const month& m) noexcept;

Returns: m / wdl.

constexpr month_weekday_last
operator/(const weekday_last& wdl, int m) noexcept;

Returns: month(m) / wdl.
constexpr year_month_day
operator/(const year_month& ym, const day& d) noexcept;

Returns: {ym.year(), ym.month(), d}.

constexpr year_month_day
operator/(const year_month& ym, int d) noexcept;

Returns: ym / day(d).

constexpr year_month_day
operator/(const year_month& ym, const month_day& md) noexcept;

Returns: y / md.month() / md.day().

constexpr year_month_day
operator/(const month_day& md, const year& y) noexcept;

Returns: y / md.

constexpr year_month_day
operator/(const month_day& md, int y) noexcept;

Returns: year(y) / md.

constexpr year_month_weekday
operator/(const year_month& ym, const weekday_indexed& wdi) noexcept;

Returns: {ym.year(), ym.month(), wdi}.

constexpr year_month_weekday
operator/(const year& y, const month_weekday& mwd) noexcept;

Returns: {y, mwd.month(), mwd.weekday_indexed()}.  

constexpr year_month_weekday
operator/(int y, const month_weekday& mwd) noexcept;

Returns: year(y) / mwd.

constexpr year_month_weekday
operator/(const month_weekday& mwd, const year& y) noexcept;

Returns: y / mwd.

constexpr year_month_weekday
operator/(const month_weekday& mwd, int y) noexcept;

Returns: year(y) / mwd.

§ 27.8.18 1263
constexpr year_month_weekday
operator/(const month_weekday& mwd, int y) noexcept;

Returns: year(y) / mwd.

constexpr year_month_weekday_last
operator/(const month_month_last& ym, const weekday_last& wdl) noexcept;

Returns: {ym.year(), ym.month(), wdl}.

constexpr year_month_weekday_last
operator/(const year& y, const month_weekday_last& mwdl) noexcept;

Returns: {y, mwdl.month(), mwdl.weekday_last()}.

constexpr year_month_weekday_last
operator/(int y, const month_weekday_last& mwdl) noexcept;

Returns: year(y) / mwdl.

constexpr year_month_weekday_last
operator/(const month_weekday_last& mwdl, const year& y) noexcept;

Returns: y / mwdl.

constexpr year_month_weekday_last
operator/(const month_weekday_last& mwdl, int y) noexcept;

Returns: year(y) / mwdl.

27.9 Class template hh_mm_ss

27.9.1 Overview

namespace std::chrono {

    template<class Duration> class hh_mm_ss {
        public:
            static constexpr unsigned fractional_width = see below;
            using precision = see below;

            constexpr hh_mm_ss() noexcept : hh_mm_ss{Duration::zero()} {}
            constexpr explicit hh_mm_ss(Duration d);
            constexpr bool is_negative() const noexcept;
            constexpr chrono::hours hours() const noexcept;
            constexpr chrono::minutes minutes() const noexcept;
            constexpr chrono::seconds seconds() const noexcept;
            constexpr precision subseconds() const noexcept;
            constexpr explicit operator precision() const noexcept;
            constexpr precision to_duration() const noexcept;

            private:
                bool is_neg;  // exposition only
                chrono::hours h;  // exposition only
                chrono::minutes m;  // exposition only
                chrono::seconds s;  // exposition only
                precision ss;  // exposition only
                
        }
    }

1 The hh_mm_ss class template splits a duration into a multi-field time structure hours:minutes:seconds and possibly subseconds, where subseconds will be a duration unit based on a non-positive power of 10. The Duration template parameter dictates the precision to which the time is split. A hh_mm_ss models negative durations with a distinct is_negative getter that returns true when the input duration is negative. The individual duration fields always return non-negative durations even when is_negative() indicates the structure is representing a negative duration.

2 If Duration is not an instance of duration, the program is ill-formed.
27.9.2 Members

```cpp
static constexpr unsigned fractional_width = see below;
```

fractional_width is the number of fractional decimal digits represented by precision. fractional_width has the value of the smallest possible integer in the range [0, 18] such that precision will exactly represent all values of Duration. If no such value of fractional_width exists, then fractional_width is 6. [Example: See Table 98 for some durations, the resulting fractional_width, and the formatted fractional second output of Duration{1}.

<table>
<thead>

<td>0.2096</td>
</tr>
</tbody>
</table>

... end example]
```

```cpp
using precision = see below;

```cpp
constexpr explicit hh_mm_ss(Duration d);
```

Effects: Constructs an object of type hh_mm_ss which represents the Duration d with precision precision.

(1) Initializes is_neg with d < Duration::zero().
(2) Initializes h with duration_cast<chrono::hours>(abs(d)).
(3) Initializes m with duration_cast<chrono::minutes>(abs(d) - hours()).
(4) Initializes s with duration_cast<chrono::seconds>(abs(d) - hours() - minutes()).
(5) If treat_as_floating_point_v<precision::rep> is true, initializes ss with abs(d) - hours() - minutes() - seconds(). Otherwise, initializes ss with duration_cast<precision>(abs(d) - hours() - minutes() - seconds()).

[Note: When precision::rep is integral and precision::period is ratio<1>, subseconds() always returns a value equal to 0s. — end note]

Postconditions: If treat_as_floating_point_v<precision::rep> is true, to_duration() returns d, otherwise to_duration() returns duration_cast<precision>(d).

```cpp
constexpr bool is_negative() const noexcept;
```

Returns: is_neg.

```cpp
constexpr chrono::hours hours() const noexcept;
```

Returns: h.

```cpp
constexpr chrono::minutes minutes() const noexcept;
```

Returns: m.
constexpr chrono::seconds seconds() const noexcept;
     Returns: s.

customexpr precision subseconds() const noexcept;
         Returns: ss.

customexpr precision to_duration() const noexcept;
         Returns: If is_neg, returns -(h + m + s + ss), otherwise returns h + m + s + ss.

customexpr explicit operator precision() const noexcept;
     Returns: to_duration().

27.9.3 Non-members

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const hh_mm_ss<Duration>& hms);
     Effects: Equivalent to:
             return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:%T}"), hms);

[Example:
     for (auto ms : {-4083007ms, 4083007ms, 65745123ms}) {
             hh_mm_ss hms{ms};
             cout << hms << "\n";
     }
     cout << hh_mm_ss{65745s} << "\n";
     Produces the output (assuming the "C" locale):
             -01:08:03.007
             01:08:03.007
             18:15:45.123
             18:15:45
     — end example]

27.10 12/24 hours functions

These functions aid in translating between a 12h format time of day and a 24h format time of day.

customexpr bool is_am(const hours& h) noexcept;
     Returns: 0h <= h && h <= 11h.

customexpr bool is_pm(const hours& h) noexcept;
     Returns: 12h <= h && h <= 23h.

customexpr hours make12(const hours& h) noexcept;
     Returns: The 12-hour equivalent of h in the range [1h, 12h]. If h is not in the range [0h, 23h], the value returned is unspecified.

customexpr hours make24(const hours& h, bool is_pm) noexcept;
     Returns: If is_pm is false, returns the 24-hour equivalent of h in the range [0h, 11h], assuming h represents an ante meridiem hour. Otherwise, returns the 24-hour equivalent of h in the range [12h, 23h], assuming h represents a post meridiem hour. If h is not in the range [1h, 12h], the value returned is unspecified.

27.11 Time zones

27.11.1 In general

27.11 describes an interface for accessing the IANA Time Zone Database that interoperates with sys_time and local_time. This interface provides time zone support to both the civil calendar types (27.8) and to user-defined calendars.
27.11.2 Time zone database

27.11.2.1 Class tzdb

```cpp
namespace std::chrono {
    struct tzdb {
        string version;
        vector<time_zone> zones;
        vector<time_zone_link> links;
        vector<leap_second> leap_seconds;

        const time_zone* locate_zone(string_view tz_name) const;
        const time_zone* current_zone() const;
    };
}
```

1 Each vector in a tzdb object is sorted to enable fast lookup.

```cpp
const time_zone* locate_zone(string_view tz_name) const;
```

2 Returns:

1. If `zones` contains an element `tz` for which `tz.name() == tz_name`, a pointer to `tz`;
2. otherwise, if `links` contains an element `tz_l` for which `tz_l.name() == tz_name`, then a pointer to the element `tz` of `zones` for which `tz.name() == tz_l.target()`.

[Note: A time_zone_link specifies an alternative name for a time_zone. — end note]

```cpp
const time_zone* current_zone() const;
```

3 Returns: A pointer to the time zone which the computer has set as its local time zone.

27.11.2.2 Class tzdb_list

```cpp
namespace std::chrono {
    class tzdb_list {
        public:
            tzdb_list(const tzdb_list&) = delete;
            tzdb_list& operator=(const tzdb_list&) = delete;

            // unspecified additional constructors

            class const_iterator;
            const tzdb& front() const noexcept;
            const_iterator erase_after(const_iterator p);
            const_iterator begin() const noexcept;
            const_iterator end() const noexcept;
            const_iterator cbegin() const noexcept;
            const_iterator cend() const noexcept;
    };
}
```

1 The tzdb_list database is a singleton; the unique object of type tzdb_list can be accessed via the `get_tzdb_list()` function. [Note: This access is only needed for those applications that need to have long uptimes and have a need to update the time zone database while running. Other applications can implicitly access the front() of this list via the read-only namespace scope functions `get_tzdb()`, `locate_zone()`, and `current_zone()`. — end note]

The tzdb_list object contains a list of tzdb objects.

2 `tzdb_list::const_iterator` is a constant iterator which meets the `Cpp17ForwardIterator` requirements and has a value type of `tzdb`.

§ 27.11.2
const tzdb& front() const noexcept;

Synchronization: This operation is thread-safe with respect to reload_tzdb(). [Note: reload_tzdb() pushes a new tzdb onto the front of this container. — end note]

Returns: A reference to the first tzdb in the container.

const_iterator erase_after(const_iterator p);

Preconditions: The iterator following p is dereferenceable.

Effects: Erases the tzdb referred to by the iterator following p.

Postconditions: No pointers, references, or iterators are invalidated except those referring to the erased tzdb. [Note: It is not possible to erase the tzdb referred to by begin(). — end note]

Returns: An iterator pointing to the element following the one that was erased, or end() if no such element exists.

Throws: Nothing.

const_iterator begin() const noexcept;

Returns: An iterator referring to the first tzdb in the container.

const_iterator end() const noexcept;

Returns: An iterator referring to the position one past the last tzdb in the container.

const_iterator cbegin() const noexcept;

Returns: begin().

const_iterator cend() const noexcept;

Returns: end().

27.11.2.3 Time zone database access

[time.zone.db.access]

tzdb_list& get_tzdb_list();

Effects: If this is the first access to the time zone database, initializes the database. If this call initializes the database, the resulting database will be a tzdb_list holding a single initialized tzdb.

Synchronization: It is safe to call this function from multiple threads at one time.

Returns: A reference to the database.

Throws: runtime_error if for any reason a reference cannot be returned to a valid tzdb_list containing one or more valid tzdbs.

const tzdb& get_tzdb();

Returns: get_tzdb_list().front().

const time_zone* locate_zone(string_view tz_name);

Returns: get_tzdb().locate_zone(tz_name).

[Note: The time zone database will be initialized if this is the first reference to the database. — end note]

const time_zone* current_zone();

Returns: get_tzdb().current_zone().

27.11.2.4 Remote time zone database support

[time.zone.db.remote]

The local time zone database is that supplied by the implementation when the program first accesses the database, for example via current_zone(). While the program is running, the implementation may choose to update the time zone database. This update shall not impact the program in any way unless the program calls the functions in this subclause. This potentially updated time zone database is referred to as the remote time zone database.

const tzdb& reload_tzdb();

Effects: This function first checks the version of the remote time zone database. If the versions of the local and remote databases are the same, there are no effects. Otherwise the remote database is pushed to the front of the tzdb_list accessed by get_tzdb_list().
Synchronization: This function is thread-safe with respect to get_tzdb_list().front() and get_tzdb_list().erase_after().

Postconditions: No pointers, references, or iterators are invalidated.

Returns: get_tzdb_list().front().

Throws: runtime_error if for any reason a reference cannot be returned to a valid tzdb.

string remote_version();

Returns: The latest remote database version.

[Note: This can be compared with get_tzdb().version to discover if the local and remote databases are equivalent. — end note]

27.11.3 Exception classes

27.11.3.1 Class nonexistent_local_time

namespace std::chrono {

    class nonexistent_local_time : public runtime_error {
        public:
            template<class Duration>
                nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);
    }
}

1 nonexistent_local_time is thrown when an attempt is made to convert a non-existent local_time to a sys_time without specifying choose::earliest or choose::latest.

    template<class Duration>
        nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);

2 Preconditions: i.result == local_info::nonexistent is true.

3 Effects: Initializes the base class with a sequence of char equivalent to that produced by os.str() initialized as shown below:

    ostringstream os;
    os << tp << " is in a gap between\n    \n    local_seconds{i.first.end.time_since_epoch()} + i.first.offset << ', '"
    << local_seconds{i.first.abbrev}
    " and\n    local_seconds{i.second.begin.time_since_epoch()} + i.second.offset << ', '"
    << i.second.abbrev
    " which are both equivalent to\n    local_seconds{i.first.end} + i.first.end << " UTC";

4 [Example]:

    #include <chrono>
    #include <iostream>

    int main() {
        using namespace std::chrono;
        try {
            auto zt = zoned_time("America/New_York",
                local_days{Sunday[2]/March/2016} + 2h + 30min);
        } catch (const nonexistent_local_time& e) {
            std::cout << e.what() << '\n';
        }
    }

    Produces the output:

    2016-03-13 02:30:00 is in a gap between
    2016-03-13 02:00:00 EST and
    2016-03-13 03:00:00 EDT which are both equivalent to
    2016-03-13 07:00:00 UTC

    — end example]
27.11.3.2 Class ambiguous_local_time

namespace std::chrono {
    class ambiguous_local_time : public runtime_error {
    public:
        template<class Duration>
        ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);
    };
}

1 ambiguous_local_time is thrown when an attempt is made to convert an ambiguous local_time to a sys_time
without specifying choose::earliest or choose::latest.

template<class Duration>
ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);

2 Preconditions: i.result == local_info::ambiguous is true.

3 Effects: Initializes the base class with a sequence of char equivalent to that produced by os.str() initialized
as shown below:

    ostringstream os;
    os << tp << " is ambiguous. It could be\n" << tp << "." << i.first.abbrev << " == 
    << tp - i.first.offset << " UTC or\n" << tp << "." << i.second.abbrev << " == 
    << tp - i.second.offset << " UTC";

4 [Example:

#include <chrono>
#include <iostream>

int main() {
    using namespace std::chrono;
    try {
        auto zt = zoned_time("America/New_York",
                        local_days(Sunday[1]/November/2016) + 1h + 30min);
    } catch (const ambiguous_local_time& e) {
        std::cout << e.what() << '\n';
    }
}

Produces the output:

2016-11-06 01:30:00 is ambiguous. It could be
2016-11-06 01:30:00 EDT == 2016-11-06 05:30:00 UTC or
2016-11-06 01:30:00 EST == 2016-11-06 06:30:00 UTC

— end example]

27.11.4 Information classes

27.11.4.1 Class sys_info

namespace std::chrono {
    struct sys_info {
        sys_seconds begin;
        sys_seconds end;
        seconds offset;
        minutes save;
        string abbrev;
    };
}

1 A sys_info object can be obtained from the combination of a time_zone and either a sys_time or local_time.
It can also be obtained from a zoned_time, which is effectively a pair of a time_zone and sys_time.

2 [Note: This type provides a low-level interface to time zone information. Typical conversions from sys_time to
local_time will use this class implicitly, not explicitly. — end note]
The `begin` and `end` data members indicate that, for the associated `time_zone` and `time_point`, the `offset` and `abbrev` are in effect in the range `[begin, end)`. This information can be used to efficiently iterate the transitions of a `time_zone`.

The `offset` data member indicates the UTC offset in effect for the associated `time_zone` and `time_point`. The relationship between `local_time` and `sys_time` is:

\[ \text{offset} = \text{local_time} - \text{sys_time} \]

The `save` data member is extra information not normally needed for conversion between `local_time` and `sys_time`. If `save != 0`min, this `sys_info` is said to be on "daylight saving" time, and `offset - save` suggests what offset this `time_zone` might use if it were off daylight saving time. However, this information should not be taken as authoritative. The only sure way to get such information is to query the `time_zone` with a `time_point` that returns a `sys_info` where `save == 0`min. There is no guarantee what `time_point` might return such a `sys_info` except that it is guaranteed not to be in the range `[begin, end)` (if `save != 0`min for this `sys_info`).

The `abbrev` data member indicates the current abbreviation used for the associated `time_zone` and `time_point`. Abbreviations are not unique among the `time_zones`, and so one cannot reliably map abbreviations back to a `time_zone` and UTC offset.

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const sys_info& r);
```

Effects: Streams out the `sys_info` object `r` in an unspecified format.

Returns: `os`.

27.11.4.2 Class `local_info` [time.zone.info.local]

```
namespace std::chrono {
    struct local_info {
        static constexpr int unique = 0;
        static constexpr int nonexistent = 1;
        static constexpr int ambiguous = 2;

        int result;
        sys_info first;
        sys_info second;
    };
}
```

[Note: This type provides a low-level interface to time zone information. Typical conversions from `local_time` to `sys_time` will use this class implicitly, not explicitly. — end note]

Describes the result of converting a `local_time` to a `sys_time` as follows:

(2.1) — When a `local_time` to `sys_time` conversion is unique, `result == unique`, `first` will be filled out with the correct `sys_info`, and `second` will be zero-initialized.

(2.2) — If the conversion stems from a nonexistent `local_time` then `result == nonexistent`, `first` will be filled out with the `sys_info` that ends just prior to the `local_time`, and `second` will be filled out with the `sys_info` that begins just after the `local_time`.

(2.3) — If the conversion stems from an ambiguous `local_time`, then `result == ambiguous`, `first` will be filled out with the `sys_info` that ends just after the `local_time`, and `second` will be filled out with the `sys_info` that starts just before the `local_time`.

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const local_info& r);
```

Effects: Streams out the `local_info` object `r` in an unspecified format.

Returns: `os`.

27.11.5 Class `time_zone` [time.zone.timezone]

27.11.5.1 Overview [time.zone.overview]

```
namespace std::chrono {
    class time_zone {

    }
}
```
A `time_zone` represents all time zone transitions for a specific geographic area. `time_zone` construction is unspecified, and performed as part of database initialization. [Note: `const time_zone` objects can be accessed via functions such as `locate_zone`. — end note]

### 27.11.5.2 Member functions

#### string_view name() const noexcept;

**Returns:** The name of the `time_zone`.  

[Example: "America/New_York". — end example]

#### template<class Duration> sys_info get_info(const sys_time<Duration>& st) const;

**Returns:** A `sys_info` for which `st` is in the range `[i.begin, i.end)`.

#### template<class Duration> local_info get_info(const local_time<Duration>& tp) const;

**Returns:** A `local_info` for `tp`.

#### template<class Duration> 

to_sys(const local_time<Duration>& tp) const;

**Returns:** A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`.  

**Throws:** If the conversion from `tp` to a `sys_time` is ambiguous, throws `ambiguous_local_time`. If the `tp` represents a non-existent time between two UTC `time_points`, throws `nonexistent_local_time`.

#### template<class Duration> 

to_sys(const local_time<Duration>& tp, choose z) const;

**Returns:** A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`. If the conversion from `tp` to a `sys_time` is ambiguous, returns the earlier `sys_time` if `z == choose::earliest`, and returns the later `sys_time` if `z == choose::latest`. If the `tp` represents a non-existent time between two UTC `time_points`, then the two UTC `time_points` will be the same, and that UTC `time_point` will be returned.
template<class Duration>
    local_time<common_type_t<Duration, seconds>>
    to_local(const sys_time<Duration>& tp) const;

Returns: The local_time associated with tp and this time_zone.

27.11.5.3 Non-member functions

bool operator==(const time_zone& x, const time_zone& y) noexcept;
Returns: x.name() == y.name().

strong_ordering operator<=>(const time_zone& x, const time_zone& y) noexcept;
Returns: x.name() <=> y.name().

27.11.6 Class template zoned_traits

namespace std::chrono {
    template<class T> struct zoned_traits {};
}

zoned_traits provides a means for customizing the behavior of zoned_time<Duration, TimeZonePtr> for the zoned_time default constructor, and constructors taking string_view. A specialization for const time_zone* is provided by the implementation:

namespace std::chrono {
    template<> struct zoned_traits<const time_zone*> {
        static const time_zone* default_zone();
        static const time_zone* locate_zone(string_view name);
    };
}

static const time_zone* default_zone();
Returns: std::chrono::locate_zone("UTC").

static const time_zone* locate_zone(string_view name);
Returns: std::chrono::locate_zone(name).

27.11.7 Class template zoned_time

27.11.7.1 Overview

namespace std::chrono {
    template<class Duration, class TimeZonePtr = const time_zone*> class zoned_time {
        using duration = common_type_t<Duration, seconds>;

    private:
        TimeZonePtr zone_; // exposition only
        sys_time<duration> tp_; // exposition only

        using traits = zoned_traits<TimeZonePtr>; // exposition only

    public:
        zoned_time();
        zoned_time(const zoned_time&) = default;
        zoned_time& operator=(const zoned_time&);

        zoned_time(const sys_time<Duration>& st);
        explicit zoned_time(TimeZonePtr z);
        explicit zoned_time(string_view name);

        template<class Duration2>
            zoned_time(const zoned_time<Duration2, TimeZonePtr>& zt);

        zoned_time(TimeZonePtr z, const sys_time<Duration>& st);
        zoned_time(string_view name, const sys_time<Duration>& st);
    };
}
zoned_time(TimeZonePtr z, const local_time<Duration>& tp);
zoned_time(string_view name, const local_time<Duration>& tp);
zoned_time(TimeZonePtr z, const local_time<Duration>& tp, choose c);
zoned_time(string_view name, const local_time<Duration>& tp, choose c);

template<class Duration2, class TimeZonePtr2>
zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& zt);
template<class Duration2, class TimeZonePtr2>
zoned_time(string_view name, const zoned_time<Duration2, TimeZonePtr2>& zt);

zoned_time& operator=(const sys_time<Duration>& st);
zoned_time& operator=(const local_time<Duration>& ut);
operator sys_time<duration>() const;
explicit operator local_time<duration>() const;
TimeZonePtr get_time_zone() const;
local_time<duration> get_local_time() const;
sys_time<duration> get_sys_time() const;
sys_info get_info() const;
};

zoned_time() -> zoned_time<seconds>;

template<class Duration>
zoned_time(sys_time<Duration>)
  -> zoned_time<common_type_t<Duration, seconds>>;

template<class TimeZonePtrOrName>
using time-zone-representation = // exposition only
cConditional_t<is_convertible_v<TimeZonePtrOrName, string_view>,
  const time_zone*,
  remove_cvref_t<TimeZonePtrOrName>>;

template<class TimeZonePtrOrName>
zoned_time(TimeZonePtrOrName&&)
  -> zoned_time<seconds, time-zone-representation<TimeZonePtrOrName>>;

template<class TimeZonePtrOrName, class Duration>
zoned_time(TimeZonePtrOrName&&, sys_time<Duration>)
  -> zoned_time<common_type_t<Duration, seconds>,
    time-zone-representation<TimeZonePtrOrName>>;

zoned_time(choose = choose::earliest)
  -> zoned_time<common_type_t<Duration, seconds>,
    time-zone-representation<TimeZonePtrOrName>>;

zoned_time(TimeZonePtrOrName&&, zoned_time<Duration, TimeZonePtr2>,
  choose = choose::earliest)
  -> zoned_time<common_type_t<Duration, seconds>,
    time-zone-representation<TimeZonePtrOrName>>;

zoned_time represents a logical pairing of a time_zone and a time_point with precision Duration. zoned_time<Duration> maintains the invariant that it always refers to a valid time zone and represents a point in time that exists and is not ambiguous in that time zone.
If `Duration` is not a specialization of `chrono::duration`, the program is ill-formed.

Every constructor of `zoned_time` that accepts a `string_view` as its first parameter does not participate in class template argument deduction (12.4.1.8).

### 27.11.7.2 Constructors

#### zoned_time()

- **Constraints:** `traits::default_zone()` is a well-formed expression.
- **Effects:** Initializes `zone_` with `traits::default_zone()` and default constructs `tp_`.

#### zoned_time(const `sys_time<Duration>`& `st`)

- **Constraints:** `traits::default_zone()` is a well-formed expression.
- **Effects:** Initializes `zone_` with `traits::default_zone()` and `tp_` with `st`.

#### explicit zoned_time(TimeZonePtr `z`)

- **Preconditions:** `z` refers to a time zone.
- **Effects:** Initializes `zone_` with `std::move(z)` and default constructs `tp_`.

#### explicit zoned_time(string_view `name`)

- **Constraints:** `traits::locate_zone(string_view{})` is a well-formed expression and `zoned_time` is constructible from the return type of `traits::locate_zone(string_view{})`.
- **Effects:** Initializes `zone_` with `traits::locate_zone(name)` and default constructs `tp_`.

#### template<class `Duration2`>

- **zoned_time(const zoned_time<`Duration2`, TimeZonePtr>& `y`)**

- **Constraints:** `is_convertible_v<sys_time<Duration2>, sys_time<Duration>>` is true.
- **Effects:** Initializes `zone_` with `y.zone_` and `tp_` with `y.tp_`.

#### zoned_time(TimeZonePtr `z`, const `sys_time<Duration>`& `st`)

- **Constraints:** `zoned_time` is constructible from the return type of `traits::locate_zone(name)` and `st`.
- **Effects:** Equivalent to construction with `{traits::locate_zone(name), st}`.

#### zoned_time(TimeZonePtr `z`, const `local_time<Duration>`& `tp`)

- **Constraints:**
  ```cpp
decay(declval<TimeZonePtr&>()->to_sys(local_time<Duration>{}, choose::earliest)),
  sys_time<duration>>
  is true.
  ```
  - **Preconditions:** `z` refers to a time zone.
  - **Effects:** Initializes `zone_` with `std::move(z)` and `tp_` with `zone_->to_sys(tp)`. 

#### zoned_time(string_view `name`, const `local_time<Duration>`& `tp`)

- **Constraints:**
  ```cpp
decay(declval<TimeZonePtr&>()->to_sys(local_time<Duration>{}, choose::earliest)),
  sys_time<duration>>
  is true.
  ```
  - **Preconditions:** `z` refers to a time zone.
  - **Effects:** Equivalent to construction with `{traits::locate_zone(name), tp}`.
is true.

21 Preconditions: z refers to a time zone.

22 Effects: Initializes zone_ with std::move(z) and tp_ with zone_->to_sys(tp, c).

zoned_time(string_view name, const local_time<Duration>& tp, choose c);

23 Constraints: zoned_time is constructible from the return type of traits::locate_zone(name), local_time<Duration>, and choose.

24 Effects: Equivalent to construction with {traits::locate_zone(name), tp, c}.

template<class Duration2, class TimeZonePtr2>
    zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& y);

25 Constraints: is_convertible_v<sys_time<Duration2>, sys_time<Duration>> is true.

26 Preconditions: z refers to a valid time zone.

27 Effects: Initializes zone_ with std::move(z) and tp_ with y.tp_.

28 [Note: The choose parameter has no effect. — end note]

template<class Duration2, class TimeZonePtr2>
    zoned_time(string_view name, const zoned_time<Duration2, TimeZonePtr2>& y);

29 Constraints: zoned_time is constructible from the return type of traits::locate_zone(name) and the type zoned_time<Duration2, TimeZonePtr2>.

30 Effects: Equivalent to construction with {traits::locate_zone(name), y}.

31 [Note: The choose parameter has no effect. — end note]

template<class Duration2, class TimeZonePtr2>
    zoned_time(string_view name, const zoned_time<Duration2, TimeZonePtr2>& y, choose c);

32 Constraints: zoned_time is constructible from the return type of traits::locate_zone(name), the type zoned_time<Duration2, TimeZonePtr2>, and the type choose.

33 Effects: Equivalent to construction with {traits::locate_zone(name), y, c}.

34 [Note: The choose parameter has no effect. — end note]

27.11.7.3 Member functions

[time.zone.zonedtime.members]

zoned_time& operator=(const sys_time<Duration>& st);

1 Effects: After assignment, get_sys_time() == st. This assignment has no effect on the return value of get_time_zone().

2 Returns: *this.

zoned_time& operator=(const local_time<Duration>& lt);

3 Effects: After assignment, get_local_time() == lt. This assignment has no effect on the return value of get_time_zone().

4 Returns: *this.

operator sys_time<duration>() const;

5 Returns: get_sys_time().

explicit operator local_time<duration>() const;

6 Returns: get_local_time().

TimeZonePtr get_time_zone() const;

7 Returns: zone_.

§ 27.11.7.3 1276
local_time<duration> get_local_time() const;

Returns: zone_->to_local(tp_).

sys_time<duration> get_sys_time() const;

Returns: tp_.

sys_info get_info() const;

Returns: zone_->get_info(tp_).

27.11.7.4 Non-member functions

template<class Duration1, class Duration2, class TimeZonePtr>
bool operator== (const zoned_time<Duration1, TimeZonePtr>& x,
const zoned_time<Duration2, TimeZonePtr>& y);

Returns: x.zone_ == y.zone_ && x.tp_ == y.tp_.

template<class charT, class traits, class Duration, class TimeZonePtr>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
const zoned_time<Duration, TimeZonePtr>& t);

Effects: Streams the value returned from t.get_local_time() to os using the format "%F %T %Z".

27.11.8 Class leap_second

27.11.8.1 Overview

namespace std::chrono {

class leap_second {

public:

leap_second(const leap_second&) = default;
leap_second& operator=(const leap_second&) = default;

// unspecified additional constructors

constexpr sys_seconds date() const noexcept;
constexpr seconds value() const noexcept;

};
}

Objects of type leap_second representing the date and value of the leap second insertions are constructed and stored in the time zone database when initialized.

2 [Example:

for (auto& l : get_tzdb().leap_seconds)
  if (l <= 2018y/March/17d)
    cout << l.date() << ": " << l.value() << 

Produces the output:

1972-07-01 00:00:00: 1s
1973-01-01 00:00:00: 1s
1974-01-01 00:00:00: 1s
1975-01-01 00:00:00: 1s
1976-01-01 00:00:00: 1s
1977-01-01 00:00:00: 1s
1978-01-01 00:00:00: 1s
1979-01-01 00:00:00: 1s
1980-01-01 00:00:00: 1s
1981-07-01 00:00:00: 1s
1982-07-01 00:00:00: 1s
1983-07-01 00:00:00: 1s
1985-07-01 00:00:00: 1s
1988-01-01 00:00:00: 1s
1990-01-01 00:00:00: 1s

§ 27.11.8.1 1277
27.11.8.2 Member functions

```cpp
constexpr sys_seconds date() const noexcept;
```

Returns: The date and time at which the leap second was inserted.

```cpp
constexpr seconds value() const noexcept;
```

Returns: +1s to indicate a positive leap second or -1s to indicate a negative leap second. [Note: All leap seconds inserted up through 2019 were positive leap seconds. — end note]

27.11.8.3 Non-member functions

```cpp
constexpr bool operator==(const leap_second& x, const leap_second& y) noexcept;
```

Returns: `x.date() == y.date()`.

```cpp
constexpr strong_ordering operator<=>(const leap_second& x, const leap_second& y) noexcept;
```

Returns: `x.date() <=> y.date()`.

```cpp
template<class Duration>
constexpr bool operator==(const leap_second& x, const sys_time<Duration>& y) noexcept;
```

Returns: `x.date() == y`.

```cpp
template<class Duration>
constexpr bool operator<(const leap_second& x, const sys_time<Duration>& y) noexcept;
```

Returns: `x.date() < y`.

```cpp
template<class Duration>
constexpr bool operator>(const sys_time<Duration>& x, const leap_second& y) noexcept;
```

Returns: `y < x`.

```cpp
template<class Duration>
constexpr bool operator<=(const leap_second& x, const sys_time<Duration>& y) noexcept;
```

Returns: `!(y < x)`.

```cpp
template<class Duration>
constexpr bool operator<=(const sys_time<Duration>& x, const leap_second& y) noexcept;
```

Returns: `!(y < x)`.
template<class Duration>
constexpr bool operator>=(const leap_second& x, const sys_time<Duration>& y) noexcept;
Returns: !(x < y).

template<class Duration>
constexpr bool operator>=(const sys_time<Duration>& x, const leap_second& y) noexcept;
Returns: !(x < y).

template<class Duration>
requires three_way_comparable_with<sys_seconds, sys_time<Duration>>
constexpr auto operator<=>(const leap_second& x, const sys_time<Duration>& y) noexcept;
Returns: x.date() <=> y.

27.11.9 Class time_zone_link

27.11.9.1 Overview

namespace std::chrono {
    class time_zone_link {
        public:
            time_zone_link(time_zone_link&&) = default;
            time_zone_link& operator=(time_zone_link&&) = default;

            // unspecified additional constructors
            string_view name() const noexcept;
            string_view target() const noexcept;
    };
}

A time_zone_link specifies an alternative name for a time_zone. time_zone_links are constructed when the

time zone database is initialized.

27.11.9.2 Member functions

string_view name() const noexcept;
Returns: The alternative name for the time zone.

string_view target() const noexcept;
Returns: The name of the time_zone for which this time_zone_link provides an alternative name.

27.11.9.3 Non-member functions

bool operator==(const time_zone_link& x, const time_zone_link& y) noexcept;
Returns: x.name() == y.name().

strong_ordering operator<=>(const time_zone_link& x, const time_zone_link& y) noexcept;
Returns: x.name() <=> y.name().

27.12 Formatting

Each formatter (20.20.5) specialization in the chrono library (27.2) meets the Formatter requirements (20.20.5.1).
The parse member functions of these formatters interpret the format specification as a chrono-format-spec according to the following syntax:

chrono-format-spec:
    fill-and-align_opt width_opt precision_opt chrono-specs_opt

chrono-specs:
    conversion-spec
    chrono-specs conversion-spec
    chrono-specs literal-char

literal-char:
    any character other than {, }, or %
The productions `fill-and-align`, `width`, and `precision` are described in 20.20.2. Giving a `precision` specification in the `chrono-format-spec` is valid only for `std::chrono::duration` types where the representation type `Rep` is a floating-point type. For all other `Rep` types, an exception of type `format_error` is thrown if the `chrono-format-spec` contains a `precision` specification. All ordinary multibyte characters represented by `literal-char` are copied unchanged to the output.

Each conversion specifier `conversion-spec` is replaced by appropriate characters as described in Table 99. Some of the conversion specifiers depend on the locale that is passed to the formatting function if the latter takes one, or the global locale otherwise. If the formatted object does not contain the information the conversion specifier refers to, an exception of type `format_error` is thrown.

The result of formatting a `std::chrono::duration` instance holding a negative value, or an `hh_mm_ss` object `h` for which `h.is_negative()` is true, is equivalent to the output of the corresponding positive value, with a `STATICALLY-WIDEN<charT>("-")` character sequence placed before the replacement of the initial conversion specifier. [Example:]

```cpp
cout << format("{:%T}", -10'000s); // prints: -02:46:40
cout << format("{:%H:%M:%S}", -10'000s); // prints: -02:46:40
cout << format("minutes {:%M, hours %H, seconds %S}", -10'000s); // prints: minutes -46, hours 02, seconds 40
```

— end example

Unless explicitly requested, the result of formatting a chrono type does not contain time zone abbreviation and time zone offset information. If the information is available, the conversion specifiers `%Z` and `%z` will format this information (respectively). [Note: If the information is not available and a `%Z` or `%z` conversion specifier appears in the `chrono-format-spec`, an exception of type `format_error` is thrown, as described above. — end note]

If the type being formatted does not contain the information that the format flag needs, an exception of type `format_error` is thrown. [Example: A duration does not contain enough information to format as a weekday. — end example] However, if a flag refers to a "time of day" (e.g. `%H`, `%I`, `%p`, etc.), then a specialization of duration is interpreted as the time of day elapsed since midnight.

<table>
<thead>

<tr>
<td>%y</td>
<td>The last two decimal digits of the year. If the result is a single digit it is prefixed by 0. The modified command %Oy produces the locale’s alternative representation. The modified command %Ey produces the locale’s alternative representation of offset from %EC (year only).</td>
</tr>
<tr>
<td>%Y</td>
<td>The year as a decimal number. If the result is less than four digits it is left-padded with 0 to four digits. The modified command %EY produces the locale’s alternative full year representation.</td>
</tr>
</tbody>
</table>
Table 99: Meaning of conversion specifiers (continued)

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>%z</td>
<td>The offset from UTC in the ISO 8601 format. For example, -0430 refers to 4 hours 30 minutes behind UTC. If the offset is zero, +0000 is used. The modified commands %Ez and %Oz insert a : between the hours and minutes: -04:30. If the offset information is not available, an exception of type format_error is thrown.</td>
</tr>
<tr>
<td>%Z</td>
<td>The time zone abbreviation. If the time zone abbreviation is not available, an exception of type format_error is thrown.</td>
</tr>
<tr>
<td>%%</td>
<td>A % character.</td>
</tr>
</tbody>
</table>

6 If the chrono-specs is omitted, the chrono object is formatted as if by streaming it to std::ostringstream os and copying os.str() through the output iterator of the context with additional padding and adjustments as specified by the format specifiers. [Example:

```cpp
string s = format("{{:=>8}}", 42ms);  // value of s is "====42ms"
```

– end example]

template<class Duration, class charT>
struct formatter<chrono::sys_time<Duration>, charT> {
    // exposition only
    local_time<Duration> time;
    // exposition only
    const string* abbrev;

    template<class OutputIterator, class...>
    auto format(OutputIterator& out, const local_time<Duration>& t) const {
        // exposition only
        return format(out, t, abbrev);
    }
}

7 Remarks: If %Z is used, it is replaced with STATICALLY-WIDEN<charT>("UTC"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted.

template<class Duration, class charT>
struct formatter<chrono::utc_time<Duration>, charT> {
    // exposition only
    local_time<Duration> time;
    // exposition only
    const string* abbrev;

    template<class OutputIterator, class...>
    auto format(OutputIterator& out, const utc_time<Duration>& t) const {
        // exposition only
        return format(out, t, abbrev);
    }
}

8 Remarks: If %Z is used, it is replaced with STATICALLY-WIDEN<charT>("UTC"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. If the argument represents a time during a positive leap second insertion, and if a seconds field is formatted, the integral portion of that format is STATICALLY-WIDEN<charT>("60").

template<class Duration, class charT>
struct formatter<chrono::tai_time<Duration>, charT> {
    // exposition only
    local_time<Duration> time;
    // exposition only
    const string* abbrev;

    template<class OutputIterator, class...>
    auto format(OutputIterator& out, const tai_time<Duration>& t) const {
        // exposition only
        return format(out, t, abbrev);
    }
}

9 Remarks: If %Z is used, it is replaced with STATICALLY-WIDEN<charT>("TAI"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. The date and time formatted are equivalent to those formatted by a sys_time initialized with

```cpp
sys_time<Duration>({tp.time_since_epoch()}) -
(sys_days({1970y/January/1}) - sys_days({1958y/January/1}))
```

template<class Duration, class charT>
struct formatter<chrono::gps_time<Duration>, charT> {
    // exposition only
    local_time<Duration> time;
    // exposition only
    const string* abbrev;

    template<class OutputIterator, class...>
    auto format(OutputIterator& out, const gps_time<Duration>& t) const {
        // exposition only
        return format(out, t, abbrev);
    }
}

10 Remarks: If %Z is used, it is replaced with STATICALLY-WIDEN<charT>("GPS"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. The date and time formatted are equivalent to those formatted by a sys_time initialized with

```cpp
sys_time<Duration>({tp.time_since_epoch()}) +
(sys_days({1980y/January/Sunday[1]}) - sys_days({1970y/January/1}))
```

template<class Duration, class charT>
struct formatter<chrono::file_time<Duration>, charT> {
    // exposition only
    local_time<Duration> time;
    // exposition only
    const string* abbrev;

    template<class OutputIterator, class...>
    auto format(OutputIterator& out, const file_time<Duration>& t) const {
        // exposition only
        return format(out, t, abbrev);
    }
}

11 Remarks: If %Z is used, it is replaced with STATICALLY-WIDEN<charT>("UTC"). If %z (or a modified variant of %z) is used, an offset of 0min is formatted. The date and time formatted are equivalent to those formatted by a sys_time initialized with clock_cast<system_clock>(t), or by a utc_time initialized with clock_cast<utc_clock>(t), where t is the first argument to format.

template<class Duration, class charT>
struct formatter<chrono::local_time<Duration>, charT> {
    // exposition only
    local_time<Duration> time;
    // exposition only
    const string* abbrev;

    template<class OutputIterator, class...>
    auto format(OutputIterator& out, const local_time<Duration>& t) const {
        // exposition only
        return format(out, t, abbrev);
    }
}

12 Remarks: If %Z, %z, or a modified version of %z is used, an exception of type format_error is thrown.
const seconds* offset_sec;  // exposition only

template<class Duration>
local_time_format_t<Duration>
local_time_format(local_time<Duration> time, const string* abbrev = nullptr,
const seconds* offset_sec = nullptr);

Returns: {time, abbrev, offset_sec}.

template<class Duration, class charT>
struct formatter<chrono::local_time_format_t<Duration>, charT>
{
    template<class FormatContext>
    typename FormatContext::iterator
    format(const chrono::local_time<Duration>& tp, FormatContext& ctx);
};

template<class FormatContext>
typename FormatContext::iterator
format(const chrono::local_time<Duration>& tp, FormatContext& ctx);

Effects: Equivalent to:
    sys_info info = tp.get_info();
    return formatter<chrono::local_time_format_t<Duration>, charT>::
        format({tp.get_local_time(), &info.abbrev, &info.offset}, ctx);

27.13 Parsing

Each parse overload specified in this subclause calls from_stream unqualified, so as to enable argument dependent
lookup (6.5.2). In the following paragraphs, let is denote an object of type basic_istream<charT, traits>& and
let I be basic_istream<charT, traits>&, where charT and traits are template parameters in that context.

template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp);

Constraints: The expression
    from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp)
is well-formed when treated as an unevaluated operand.

Returns: A manipulator such that the expression is >> parse(fmt, tp) has type I, has value is, and calls
from_stream(is, fmt.c_str(), tp).

template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
    basic_string<charT, traits, Alloc>& abbrev);

Constraints: The expression
    from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp, addressof(abbrev))
is well-formed when treated as an unevaluated operand.

Returns: A manipulator such that the expression is >> parse(fmt, tp, abbrev) has type I, has value is, and calls from_stream(is, fmt.c_str(), tp, addressof(abbrev)).
template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
minutes& offset);

Constraints: The expression
from_stream(declval<basic_istream<charT, traits>&>(),
fmt.c_str(), tp,
decval<basic_string<charT, traits, Alloc>*>(nullptr),
&offset)
is well-formed when treated as an unevaluated operand.

Returns: A manipulator such that the expression is >> parse(fmt, tp, offset) has type I, has value is,
and calls:
from_stream(is,
fmt.c_str(), tp,
static_cast<basic_string<charT, traits, Alloc>*>(nullptr),
&offset)

template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
basic_string<charT, traits, Alloc>& abbrev, minutes& offset);

Constraints: The expression
from_stream(declval<basic_istream<charT, traits>&>(),
fmt.c_str(), tp, addressof(abbrev), &offset)
is well-formed when treated as an unevaluated operand.

Returns: A manipulator such that the expression is >> parse(fmt, tp, abbrev, offset) has type I, has
value is, and calls from_stream(is, fmt.c_str(), tp, addressof(abbrev), &offset).

All from_stream overloads behave as unformatted input functions, except that they have an unspecified effect
on the value returned by subsequent calls to basic_istream<>::gcount(). Each overload takes a format string
containing ordinary characters and flags which have special meaning. Each flag begins with a %. Some flags can
be modified by E or O. During parsing each flag interprets characters as parts of date and time types according
to Table 100. Some flags can be modified by a width parameter given as a positive decimal integer called out as $N$
below which governs how many characters are parsed from the stream in interpreting the flag. All characters in the
format string that are not represented in Table 100, except for white space, are parsed unchanged from the stream. A
white space character matches zero or more white space characters in the input stream.

If the type being parsed cannot represent the information that the format flag refers to, is.setstate(ios_base::failbit) is called. [Example: A duration cannot represent a weekday. — end example] However, if a flag
refers to a "time of day" (e.g. %H, %I, %p, etc.), then a specialization of duration is parsed as the time of day elapsed
since midnight.

If the from_stream overload fails to parse everything specified by the format string, or if insufficient information is
parsed to specify a complete duration, time point, or calendrical data structure, setstate(ios_base::failbit) is
called on the basic_istream.

Table 100: Meaning of parse flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Parsed value</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>The locale’s full or abbreviated case-insensitive weekday name.</td>
</tr>
<tr>

27.14 Header <ctime> synopsis

```cpp
#define NULL see 17.2.3
#define CLOCKS_PER_SEC see below
#define TIME_UTC see below

namespace std {
    using size_t = see 17.2.4;
    using clock_t = see below;
    using time_t = see below;

    struct timespec;
    struct tm;

    clock_t clock();
    double difftime(time_t time1, time_t time0);
    time_t mktime(struct tm* tmpt);`
time_t time(time_t* timer);
int timespec_get(timespec* ts, int base);
char* asctime(const struct tm* timeptr);
char* ctime(const time_t* timer);
struct tm* gmtime(const time_t* timer);
struct tm* localtime(const time_t* timer);
size_t strftime(char* s, size_t maxsize, const char* format, const struct tm* timeptr);
}

1 The contents of the header `<ctime>` are the same as the C standard library header `<time.h>`. ²⁵⁵
2 The functions asctime, ctime, gmtime, and localtime are not required to avoid data races (16.5.5.10).

See also: ISO C 7.27

²⁵⁵) `strftime` supports the C conversion specifiers `C, D, e, F, g, G, h, r, R, t, T, u, V, and z`, and the modifiers `E` and `D`.
28 Localization library

28.1 General

This Clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

The following subclauses describe components for locales themselves, the standard facets, and facilities from the ISO C library, as summarized in Table 101.

28.2 Header <locale> synopsis

```cpp
namespace std {
  // 28.3.1, locale
  class locale;
  template<class Facet> const Facet& use_facet(const locale&);
  template<class Facet> bool has_facet(const locale&) noexcept;

  // 28.3.3, convenience interfaces
  template<class charT> bool isspace (charT c, const locale& loc);
  template<class charT> bool isprint (charT c, const locale& loc);
  template<class charT> bool iscntrl (charT c, const locale& loc);
  template<class charT> bool isupper (charT c, const locale& loc);
  template<class charT> bool islower (charT c, const locale& loc);
  template<class charT> bool isalpha (charT c, const locale& loc);
  template<class charT> bool isdigit (charT c, const locale& loc);
  template<class charT> bool ispunct (charT c, const locale& loc);
  template<class charT> bool isxdigit(charT c, const locale& loc);
  template<class charT> bool isalnum (charT c, const locale& loc);
  template<class charT> bool isgraph (charT c, const locale& loc);
  template<class charT> bool isblank (charT c, const locale& loc);
  template<class charT> charT toupper(charT c, const locale& loc);
  template<class charT> charT tolower(charT c, const locale& loc);

  // 28.4.1, ctype
  class ctype_base;
  template<class charT> class ctype;
  template<> class ctype<char>;
  template<class charT> class ctype_byname;  // specialization
  class codecvt_base;
  template<class internT, class externT, class stateT> class codecvt;
  template<class internT, class externT, class stateT> class codecvt_byname;

  // 28.4.2, numeric
  template<class charT, class InputIterator = istreambuf_iterator<charT>>
  class num_get;
  template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
  class num_put;
  template<class charT>
  class numnumpunct;
  template<class charT>
  class numnumpunct_byname;
}
```

§ 28.2
The header `<locale>` defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.\(^{256}\)

### 28.3 Locales

#### 28.3.1 Class `locale`

```cpp
namespace std {
    class locale {
        public:
            // types
            class facet;
            class id;
            using category = int;
            static const category none = 0,
                           collate = 0x010, ctype = 0x020,
                           monetary = 0x040, numeric = 0x080,
                           time = 0x100, messages = 0x200,
                           all = collate | ctype | monetary | numeric | time | messages;

            // construct/copy/destroy
            locale() noexcept;
            locale(const locale& other) noexcept;
            explicit locale(const char* std_name);
            explicit locale(const string& std_name);
            locale(const locale& other, const char* std_name, category);
            locale(const locale& other, const string& std_name, category);
            template<class Facet> locale(const locale& other, Facet* f);
            locale(const locale& other, const locale& one, category);
            "locale()"; // not virtual
            const locale& operator=(const locale& other) noexcept;
```

\(^{256}\)In this subclause, the type name `struct tm` is an incomplete type that is defined in `<ctime>` (27.14).
template<class Facet> locale combine(const locale& other) const;

// locale operations
string name() const;

bool operator==(const locale& other) const;

template<class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1,
                const basic_string<charT, traits, Allocator>& s2) const;

// global locale objects
static locale global(const locale&);
static const locale& classic();
};

Class locale implements a type-safe polymorphic set of facets, indexed by facet type. In other words, a facet has a dual role: in one sense, it’s just a class interface; at the same time, it’s an index into a locale’s set of facets.

Access to the facets of a locale is via two function templates, use_facet<> and has_facet<>.

[Example: An iostream operator<< might be implemented as:

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<< (basic_ostream<charT, traits>& s, Date d) {
    typename basic_ostream<charT, traits>::sentry cerberos(s);
    if (cerberos) {
        tm tmbuf; d.extract(tmbuf);
        bool failed =
                    use_facet<time_put<charT, ostreambuf_iterator<charT, traits>>>(
                        s.getloc()).put(s, s, s.fill(), &tmbuf, 'x').failed();
        if (failed)
            s.setstate(s.badbit);  // might throw
    }
    return s;
}
```
— end example]

In the call to use_facet<Facet>(loc), the type argument chooses a facet, making available all members of the named type. If Facet is not present in a locale, it throws the standard exception bad_cast. A C++ program can check if a locale implements a particular facet with the function template has_facet<Facet>(). User-defined facets may be installed in a locale, and used identically as may standard facets.

[Note: All locale semantics are accessed via use_facet<> and has_facet<> , except that:

(5.1) A member operator template operator() (const basic_string<C, T, A>& k, const basic_string<C, T, A>&) is provided so that a locale may be used as a predicate argument to the standard collections, to collate strings.

(5.2) Convenient global interfaces are provided for traditional ctype functions such as isdigit() and isspace(), so that given a locale object loc a C++ program can call isspace(c, loc). (This eases upgrading existing extractors (29.7.4.2).) ]

— end note]

Once a facet reference is obtained from a locale object by calling use_facet<>, that reference remains usable, and the results from member functions of it may be cached and re-used, as long as some locale object refers to that facet.

In successive calls to a locale facet member function on a facet object installed in the same locale, the returned result shall be identical.

A locale constructed from a name string (such as "POSIX"), or from parts of two named locales, has a name; all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies of) itself. For an unnamed locale, locale::name() returns the string "*".
Whether there is one global locale object for the entire program or one global locale object per thread is implementation-defined. Implementations should provide one global locale object per thread. If there is a single global locale object for the entire program, implementations are not required to avoid data races on it (16.5.5.10).

28.3.1.1 Types [locale.types]

28.3.1.1.1 Type locale::category [locale.category]

using category = int;

Valid category values include the locale member bitmask elements collate, ctype, monetary, numeric, time, and messages, each of which represents a single locale category. In addition, locale member bitmask constant none is defined as zero and represents no category. And locale member bitmask constant all is defined such that the expression

\[(\text{collate } | \text{ctype } | \text{monetary } | \text{numeric } | \text{time } | \text{messages } | \text{all}) == \text{all}\]

is true, and represents the union of all categories. Further, the expression \((X \mid Y)\), where \(X\) and \(Y\) each represent a single category, represents the union of the two categories.

locale member functions expecting a category argument require one of the category values defined above, or the union of two or more such values. Such a category value identifies a set of locale categories. Each locale category, in turn, identifies a set of locale facets, including at least those shown in Table 102.

### Table 102: Locale category facets [tab:locale.category.facets]

<table>

</tr>
<tr>
<td>messages</td>
<td>messages&lt;char&gt;, messages&lt;wchar_t&gt;</td>
</tr>
</tbody>
</table>

For any locale loc either constructed, or returned by locale::classic(), and any facet facet shown in Table 102, has_facet<Facet>(loc) is true. Each locale member function which takes a locale::category argument operates on the corresponding set of facets.

An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in Table 103.

The provided implementation of members of facets num_get<charT> and num_put<charT> calls use_facet<C>( loc ) only for facet \( F \) of types numpunct<charT> and ctype<charT>, and for locale \( l \) the value obtained by calling member getloc() on the ios_base& argument to these functions.

In declarations of facets, a template parameter with name InputIterator or OutputIterator indicates the set of all possible specializations on parameters that meet the Cpp17InputIterator requirements or Cpp17OutputIterator requirements, respectively (23.3). A template parameter with name C represents the set of types containing char, wchar_t, and any other implementation-defined character types that meet the requirements for a character on which any of the iostream components can be instantiated. A template parameter with name International represents the set of all possible specializations on a bool parameter.
Table 103: Required specializations

28.3.1.1.2 Class locale::facet  

namespace std {
    class locale::facet {
        protected:
            explicit facet(size_t refs = 0);
            virtual ~facet();
            facet(const facet&) = delete;
            void operator=(const facet&) = delete;
        };
    }

1 Class facet is the base class for locale feature sets. A class is a facet if it is publicly derived from another facet, or if it is a class derived from locale::facet and contains a publicly accessible declaration as follows:\[258\]

    static ::std::locale::id id;

2 Template parameters in this Clause which are required to be facets are those named Facet in declarations. A program that passes a type that is not a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a Facet template parameter.

3 The refs argument to the constructor is used for lifetime management. For refs == 0, the implementation performs delete static_cast<locale::facet*>(f) (where f is a pointer to the facet) when the last locale object containing the facet is destroyed; for refs == 1, the implementation never destroys the facet.

4 Constructors of all facets defined in this Clause take such an argument and pass it along to their facet base class constructor. All one-argument constructors defined in this Clause are explicit, preventing their participation in automatic conversions.

5 For some standard facets a standard ...byname class, derived from it, implements the virtual function semantics equivalent to that facet of the locale constructed by locale(const char*) with the same name. Each such facet provides a constructor that takes a const char* argument, which names the locale, and a refs argument, which is passed to the base class constructor. Each such facet also provides a constructor that takes a string argument str and a refs argument, which has the same effect as calling the first constructor with the two arguments str.c_str() (258) This is a complete list of requirements; there are no other requirements. Thus, a facet class need not have a public copy constructor, assignment, default constructor, destructor, etc.

\[\S 28.3.1.1.2\]
and refs. If there is no "-_byname" version of a facet, the base class implements named locale semantics itself by reference to other facets.

28.3.1.1.3 Class locale::id

```
namespace std {

    class locale::id {
        public:
            id();
            void operator=(const id&) = delete;
            id(const id&) = delete;
    };
}
```

1 The class `locale::id` provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

2 [Note: Because facets are used by iostreams, potentially while static constructors are running, their initialization cannot depend on programmed static initialization. One initialization strategy is for `locale` to initialize each facet's id member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (6.9.3.2). — end note]

28.3.1.2 Constructors and destructor

```locale() noexcept;`n
1 Effects: Constructs a copy of the argument last passed to `locale::global(locale&)`, if it has been called; else, the resulting facets have virtual function semantics identical to those of `locale::classic()`. [Note: This constructor yields a copy of the current global locale. It is commonly used as a default argument for function parameters of type `const locale&`. — end note]

explicit locale(const char* std_name);
2 Effects: Constructs a locale using standard C locale names, e.g., "POSIX". The resulting locale implements semantics defined to be associated with that name.
3 Throws: `runtime_error` if the argument is not valid, or is null.
4 Remarks: The set of valid string argument values is "C", ",", and any implementation-defined values.

explicit locale(const string& std_name);
5 Effects: The same as `locale(std_name.c_str())`.

locale(const locale& other, const char* std_name, category);
6 Effects: Constructs a locale as a copy of other except for the facets identified by the category argument, which instead implement the same semantics as `locale(std_name)`.
7 Throws: `runtime_error` if the argument is not valid, or is null.
8 Remarks: The locale has a name if and only if other has a name.

locale(const locale& other, const string& std_name, category cat);
9 Effects: The same as `locale(other, std_name.c_str(), cat)`.

template<class Facet> locale(const locale& other, Facet* f);
10 Effects: Constructs a locale incorporating all facets from the first argument except that of type Facet, and installs the second argument as the remaining facet. If f is null, the resulting object is a copy of other.
11 Remarks: The resulting locale has no name.

locale(const locale& other, const locale& one, category cats);
12 Effects: Constructs a locale incorporating all facets from the first argument except those that implement cats, which are instead incorporated from the second argument.
13 Remarks: The resulting locale has a name if and only if the first two arguments have names.
const locale& operator=(const locale& other) noexcept;

Effects: Creates a copy of other, replacing the current value.

Returns: *this.

28.3.1.3 Members

template<class Facet> locale combine(const locale& other) const;

Effects: Constructs a locale incorporating all facets from *this except for that one facet of other that is
identified by Facet.

Returns: The newly created locale.

Throws: runtime_error if has_facet<Facet>(other) is false.

Remarks: The resulting locale has no name.

string name() const;

Returns: The name of *this, if it has one; otherwise, the string "*".

28.3.1.4 Operators

bool operator==(const locale& other) const;

Returns: true if both arguments are the same locale, or one is a copy of the other, or each has a name and the
names are identical; false otherwise.

template<class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1,
const basic_string<charT, traits, Allocator>& s2) const;

Effects: Compares two strings according to the collate<charT> facet.

Returns:

use_facet<collate<charT>>(*this).compare(s1.data(), s1.data() + s1.size(),
 s2.data(), s2.data() + s2.size()) < 0

Remarks: This member operator template (and therefore locale itself) meets the requirements for a comparator
predicate template argument (Clause 25) applied to strings.

[Example: A vector of strings v can be collated according to collation rules in locale loc simply by (25.8.1,
22.3.11):

std::sort(v.begin(), v.end(), loc);
— end example]

28.3.1.5 Static members

static locale global(const locale& loc);

Effects: Sets the global locale to its argument. Causes future calls to the constructor locale() to return a copy
of the argument. If the argument has a name, does
setlocale(LC_ALL, loc.name().c_str());
otherwise, the effect on the C locale, if any, is implementation-defined.

Returns: The previous value of locale().

Remarks: No library function other than locale::global() affects the value returned by locale(). [Note: See
28.5 for data race considerations when setlocale is invoked. — end note]

static const locale& classic();

The "C" locale.

Returns: A locale that implements the classic "C" locale semantics, equivalent to the value locale("C").

Remarks: This locale, its facets, and their member functions, do not change with time.
28.3.2 locale globals

```
template<class Facet> const Facet& use_facet(const locale& loc);
```

**Mandates:** `Facet` is a facet class whose definition contains the public static member `id` as defined in 28.3.1.2.

**Returns:** A reference to the corresponding facet of `loc`, if present.

**Throws:** `bad_cast` if `has_facet<Facet>(loc)` is false.

**Remarks:** The reference returned remains valid at least as long as any copy of `loc` exists.

```
template<class Facet> bool has_facet(const locale& loc) noexcept;
```

**Returns:** `true` if the facet requested is present in `loc`; otherwise `false`.

28.3.3 Convenience interfaces

28.3.3.1 Character classification

```
template<class charT> bool isspace (charT c, const locale& loc);
template<class charT> bool isprint (charT c, const locale& loc);
template<class charT> bool iscntrl (charT c, const locale& loc);
template<class charT> bool isupper (charT c, const locale& loc);
template<class charT> bool islower (charT c, const locale& loc);
template<class charT> bool isalpha (charT c, const locale& loc);
template<class charT> bool isdigit (charT c, const locale& loc);
template<class charT> bool ispunct (charT c, const locale& loc);
template<class charT> bool isxdigit (charT c, const locale& loc);
template<class charT> bool isalnum (charT c, const locale& loc);
template<class charT> bool isgraph (charT c, const locale& loc);
template<class charT> bool isblank (charT c, const locale& loc);
```

Each of these functions `isF` returns the result of the expression:

```
use_facet<ctype<charT>>(loc).is(ctype_base::F, c)
```

where `F` is the `ctype_base::mask` value corresponding to that function (28.4.1).

28.3.3.2 Conversions

```
template<class charT> charT toupper (charT c, const locale& loc);
```

**Returns:** `use_facet<ctype<charT>>(loc).toupper(c)`.

```
template<class charT> charT tolower (charT c, const locale& loc);
```

**Returns:** `use_facet<ctype<charT>>(loc).tolower(c)`.

28.4 Standard locale categories

Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a datum, for use by standard or users’ iostream operators `<<` and `>>, as members `put()` and `get()`, respectively. Each such member function takes an `ios_base&` argument whose members `flags()`, `precision()`, and `width()`, specify the format of the corresponding datum (29.5.3). Those functions which need to use other facets call its member `getloc()` to retrieve the locale imbued there. Formatting facets use the character argument `fill` to fill out the specified width where necessary.

The `put()` members make no provision for error reporting. (Any failures of the OutputIterator argument can be extracted from the returned iterator.) The `get()` members take an `ios_base::iostate&` argument whose value they ignore, but set to `ios_base::failbit` in case of a parse error.

Within this Clause it is unspecified whether one virtual function calls another virtual function.

28.4.1 The ctype category

```
namespace std {
  class ctype_base {
    public:
      using mask = see below;
  }
```

259) When used in a loop, it is faster to cache the `ctype<>` facet and use it directly, or use the vector form of `ctype<>::is`. 

§ 28.4.1 1295
The type mask is a bitmask type (16.4.2.2.4).

Class `ctype` encapsulates the C library `<cctype>` features. `istream` members are required to use `ctype<>` for character classing during input parsing.
The specializations required in Table 102 (28.3.1.1.1), namely `ctype<char>` and `ctype<wchar_t>`, implement character classing appropriate to the implementation’s native character set.

### 28.4.1.1.1 ctype members

```cpp
bool    is(mask m, charT c) const;
const charT* is(const charT* low, const charT* high, mask* vec) const;
Returns: do_is(m, c) or do_is(low, high, vec).

const charT* scan_is(mask m, const charT* low, const charT* high) const;
Returns: do_scan_is(m, low, high).

const charT* scan_not(mask m, const charT* low, const charT* high) const;
Returns: do_scan_not(m, low, high).

charT    toupper(charT) const;
const charT* toupper(charT* low, const charT* high) const;
Returns: do_toupper(c) or do_toupper(low, high).

charT    tolower(charT c) const;
const charT* tolower(charT* low, const charT* high) const;
Returns: do_tolower(c) or do_tolower(low, high).

charT    widen(char c) const;
const char* widen(const char* low, const char* high, charT* to) const;
Returns: do_widen(c) or do_widen(low, high, to).

char    narrow(charT c, char dfault) const;
const charT* narrow(const charT* low, const charT* high, char dfault, char* to) const;
Returns: do_narrow(c, dfault) or do_narrow(low, high, dfault, to).
```

### 28.4.1.1.2 ctype virtual functions

```cpp
bool    do_is(mask m, charT c) const;
const charT* do_is(const charT* low, const charT* high, mask* vec) const;
Effects: Classifies a character or sequence of characters. For each argument character, identifies a value \( M \) of type `ctype_base::mask`. The second form identifies a value \( M \) of type `ctype_base::mask` for each \( *p \) where (low \( \leq p \&\& p < \) high), and places it into vec[\( p - \) low].
Returns: The first form returns the result of the expression \( (M \& m) \neq 0 \); i.e., true if the character has the characteristics specified. The second form returns high.

const charT* do_scan_is(mask m, const charT* low, const charT* high) const;
Effects: Locates a character in a buffer that conforms to a classification \( m \).
Returns: The smallest pointer \( p \) in the range \( [\text{low}, \text{high}) \) such that \( \text{is}(m, *p) \) would return true; otherwise, returns high.

const charT* do_scan_not(mask m, const charT* low, const charT* high) const;
Effects: Locates a character in a buffer that fails to conform to a classification \( m \).
Returns: The smallest pointer \( p \), if any, in the range \( [\text{low}, \text{high}) \) such that \( \text{is}(m, *p) \) would return false; otherwise, returns high.

charT    do_toupper(charT c) const;
const charT* do_toupper(charT* low, const charT* high) const;
Effects: Converts a character or characters to upper case. The second form replaces each character \( *p \) in the range \( [\text{low}, \text{high}) \) for which a corresponding upper-case character exists, with that character.
Returns: The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns high.
```
Effects: Converts a character or characters to lower case. The second form replaces each character *p in the range [low, high) and for which a corresponding lower-case character exists, with that character.

Returns: The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns high.

Effects: Applies the simplest reasonable transformation from a char value or sequence of char values to the corresponding charT value or values.\(^{260}\) The only characters for which unique transformations are required are those in the basic source character set (5.3).

For any named ctype category with a ctype <charT> facet ctc and valid ctype_base::mask value M, 
\[
\text{ctc.is}(M, c) \text{ || !is}(M, \text{do_widen}(c)) \]

is true.\(^{261}\) The second form transforms each character *p in the range [low, high), placing the result in dest[p - low].

Returns: The first form returns the transformed value. The second form returns high.

Effects: Applies the simplest reasonable transformation from a charT value or sequence of charT values to the corresponding char value or values. For any character c in the basic source character set (5.3) the transformation is such that do_widen(do_narrow(c, 0)) == c.

For any named ctype category with a ctype<char> facet ctc however, and ctype_base::mask value M,
\[
\text{is}(M, c) \text{ || !ctc.is}(M, \text{do_narrow}(c, \text{default}))
\]

is true (unless do_narrow returns default). In addition, for any digit character c, the expression (do_narrow(c, default) - '0') evaluates to the digit value of the character. The second form transforms each character *p in the range [low, high), placing the result (or default if no simple transformation is readily available) in dest[p - low].

Returns: The first form returns the transformed value; or default if no mapping is readily available. The second form returns high.

28.4.1.2 Class template ctype_byname
[locale ctype byname]

namespace std {
    template<class charT>
    class ctype_byname : public ctype<charT> {
        public:
            using mask = typename ctype<charT>::mask;
            explicit ctype_byname(const char*, size_t refs = 0);
            explicit ctype_byname(const string&, size_t refs = 0);
        protected:
            ~ctype_byname();
        }
    }

28.4.1.3 ctype<char> specialization
[facet ctype special]

namespace std {
    template<>
    class ctype<char> : public locale::facet, public ctype_base {
        public:
            using char_type = char;

\(^{260}\) The char argument of do_widen is intended to accept values derived from character-literals for conversion to the locale’s encoding.

\(^{261}\) In other words, the transformed character is not a member of any character classification that c is not also a member of.
explicit ctype(const mask* tab = nullptr, bool del = false, size_t refs = 0);

bool is(mask m, char c) const;
const char* is(const char* low, const char* high, mask* vec) const;
const char* scan_is (mask m, const char* low, const char* high) const;
const char* scan_not(mask m, const char* low, const char* high) const;

char toupper(char c) const;
const char* toupper(char* low, const char* high) const;
char tolower(char c) const;
const char* tolower(char* low, const char* high) const;

char widen(char c) const;
const char* widen(const char* low, const char* high) const;
char narrow(char c, char dfault) const;
const char* narrow(const char* low, const char* high, char dfault, char* to) const;

static locale::id id;
static const size_t table_size = implementation-defined;
const mask* table() const noexcept;
static const mask* classic_table() noexcept;

protected:
~ctype();
virtual char do_toupper(char c) const;
virtual const char* do_toupper(char* low, const char* high) const;
virtual char do_tolower(char c) const;
virtual const char* do_tolower(char* low, const char* high) const;

virtual char do_widen(char c) const;
virtual const char* do_widen(const char* low, const char* high) const;
virtual char do_narrow(char c, char dfault) const;
virtual const char* do_narrow(const char* low, const char* high, char dfault, char* to) const;

};

1 A specialization ctype<char> is provided so that the member functions on type char can be implemented inline. The implementation-defined value of member table_size is at least 256.

28.4.1.3.1 Destructor [facet.ctype.char.dtor]
~ctype();

Effects: If the constructor’s first argument was nonzero, and its second argument was true, does delete [] table().

28.4.1.3.2 Members [facet.ctype.char.members]

In the following member descriptions, for unsigned char values v where v >= table_size, table()[v] is assumed to have an implementation-specific value (possibly different for each such value v) without performing the array lookup.

explicit ctype(const mask* tbl = nullptr, bool del = false, size_t refs = 0);

2 Preconditions: Either tbl == nullptr is true or [tbl, tbl+table_size) is a valid range.

Effects: Passes its refs argument to its base class constructor.

bool is(mask m, char c) const;
const char* is(const char* low, const char* high, mask* vec) const;

4 Effects: The second form, for all *p in the range [low, high), assigns into vec[p - low] the value table()[(unsigned char)*p].
Returns: The first form returns \( \text{table}()[\text{(unsigned char)} c] \) & m; the second form returns high.

\[
\text{const char* scan_is(mask m, const char* low, const char* high) const;}
\]

Returns: The smallest \( p \) in the range \([\text{low}, \text{high})\) such that
\[
\text{table}()[\text{(unsigned char)} *p] \& m
\]
is true.

\[
\text{const char* scan_not(mask m, const char* low, const char* high) const;}
\]

Returns: The smallest \( p \) in the range \([\text{low}, \text{high})\) such that
\[
\text{table}()[\text{(unsigned char)} *p] \& m
\]
is false.

\[
\text{char toupper(char c) const;}
\]

\[
\text{const char* toupper(char* low, const char* high) const;}
\]

Returns: do_toupper(c) or do_toupper(low, high), respectively.

\[
\text{char tolower(char c) const;}
\]

\[
\text{const char* tolower(char* low, const char* high) const;}
\]

Returns: do_tolower(c) or do_tolower(low, high), respectively.

\[
\text{char widen(char c) const;}
\]

\[
\text{const char* widen(const char* low, const char* high, char* to) const;}
\]

Returns: do_widen(c) or do_widen(low, high, to), respectively.

\[
\text{char narrow(char c, char dfault) const;}
\]

\[
\text{const char* narrow(const char* low, const char* high, char dfault, char* to) const;}
\]

Returns: do_narrow(c, dfault) or do_narrow(low, high, dfault, to), respectively.

\[
\text{const mask* table() const noexcept;}
\]

Returns: The first constructor argument, if it was nonzero, otherwise classic_table().

28.4.1.3.3 Static members

\[
\text{static const mask* classic_table() noexcept;}
\]

Returns: A pointer to the initial element of an array of size table_size which represents the classifications of characters in the "C" locale.

28.4.1.3.4 Virtual functions

\[
\text{class codecvt_base {}
\]

\[
\text{enum result { ok, partial, error, noconv };}
\]

These functions are described identically as those members of the same name in the ctype class template (28.4.1.1.1).

28.4.1.4 Class template codecvt

\[
\text{namespace std {}
\]

\[
\text{class codecvt_base {}
\]

\[
\text{public:}
\]

\[
\text{enum result { ok, partial, error, noconv };}
\]

\[
\text{}}}
\]

§ 28.4.1.4 1300
The class `codecvt<internT, externT, stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as UTF-32 and EUC.

The `stateT` argument selects the pair of character encodings being mapped between.

The specializations required in Table 102 (28.3.1.1.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char8_t, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt<char32_t, char8_t, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for ordinary and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a program-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized do_in or do_out members.
28.4.1.4.1 Members

\[\text{locale.codecvt.members}\]

result out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;  
\[\text{Returns: do\_out(state, from, from\_end, from\_next, to, to\_end, to\_next).}\]

result unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;  
\[\text{Returns: do\_unshift(state, to, to\_end, to\_next).}\]

result in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;  
\[\text{Returns: do\_in(state, from, from\_end, from\_next, to, to\_end, to\_next).}\]

int encoding() const noexcept;  
\[\text{Returns: do\_encoding().}\]

bool always_noconv() const noexcept;  
\[\text{Returns: do\_always\_noconv().}\]

int length(stateT& state, const externT* from, const externT* from_end, size_t max) const;  
\[\text{Returns: do\_length(state, from, from\_end, max).}\]

int max_length() const noexcept;  
\[\text{Returns: do\_max\_length().}\]

28.4.1.4.2 Virtual functions

\[\text{locale.codecvt.virtuals}\]

result do_out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

result do_in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;  
\[\text{Preconditions: (from <= from\_end && to <= to\_end) is well-defined and true; state is initialized, if at}
\[\text{the beginning of a sequence, or else is equal to the result of converting the preceding characters in the sequence.}\]

\[\text{Effects: Translates characters in the source range [from, from\_end), placing the results in sequential positions}
\[\text{starting at destination to. Converts no more than (from\_end - from) source elements, and stores no more}
\[\text{than (to\_end - to) destination elements.}\]

\[\text{Stops if it encounters a character it cannot convert. It always leaves the from\_next and to\_next pointers}
\[\text{pointing one beyond the last element successfully converted. If returns noconv, internT and externT are}
\[\text{the same type and the converted sequence is identical to the input sequence [from, from\_next). to\_next}
\[\text{is set equal to to, the value of state is unchanged, and there are no changes to the values in [to, to\_end).}\]

\[\text{A codecvt facet that is used by basic\_filebuf (29.9) shall have the property that if}\]

\[\text{do\_out(state, from, from\_end, from\_next, to, to\_end, to\_next) would return ok, where from != from\_end, then}\]

\[\text{do\_out(state, from, from + 1, from\_next, to, to\_end, to\_next) shall also return ok, and that if}\]

\[\text{do\_in(state, from, from\_end, from\_next, to, to\_end, to\_next) would return ok, where to != to\_end, then}\]

\[\text{do\_in(state, from, from\_end, from\_next, to, to + 1, to\_next)}\]
shall also return ok. [Note: As a result of operations on state, it can return ok or partial and set from_next == from and to_next != to. — end note]

Remarks: Its operations on state are unspecified. [Note: This argument can be used, for example, to maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek offsets. — end note]

Returns: An enumeration value, as summarized in Table 104.

Table 104: do_in/do_out result values  [tab:locale.codecvt.inout]

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the conversion</td>
</tr>
<tr>
<td>partial</td>
<td>not all source characters converted</td>
</tr>
<tr>
<td>error</td>
<td>encountered a character in [from, from_end) that it could not convert</td>
</tr>
<tr>
<td>noconv</td>
<td>internT and externT are the same type, and input sequence is identical to converted sequence</td>
</tr>
</tbody>
</table>

A return value of partial, if (from_next == from_end), indicates that either the destination sequence has not absorbed all the available destination elements, or that additional source elements are needed before another destination element can be produced.

result do_unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

Preconditions: (to <= to_end) is well-defined and true; state is initialized, if at the beginning of a sequence, or else is equal to the result of converting the preceding characters in the sequence.

Effects: Places characters starting at to that should be appended to terminate a sequence when the current stateT is given by state. Stores no more than (to_end - to) destination elements, and leaves the to_next pointer pointing one beyond the last element successfully stored.

Returns: An enumeration value, as summarized in Table 105.

Table 105: do_unshift result values  [tab:locale.codecvt.unshift]

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the sequence</td>
</tr>
<tr>
<td>partial</td>
<td>space for more than to_end - to destination elements needed to terminate a sequence given the value of state</td>
</tr>
<tr>
<td>error</td>
<td>an unspecified error has occurred</td>
</tr>
<tr>
<td>noconv</td>
<td>no termination is needed for this state_type</td>
</tr>
</tbody>
</table>

int do_encoding() const noexcept;

Returns: -1 if the encoding of the externT sequence is state-dependent; else the constant number of externT characters needed to produce an internal character; or 0 if this number is not a constant.

bool do_always_noconv() const noexcept;

Returns: true if do_in() and do_out() return noconv for all valid argument values. codecvt<char, char, mbstate_t> returns true.

int do_length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

Preconditions: (from <= from_end) is well-defined and true; state is initialized, if at the beginning of a sequence, or else is equal to the result of converting the preceding characters in the sequence.

263) Informally, this means that basic_filebuf assumes that the mappings from internal to external characters is 1 to N: a codecvt facet that is used by basic_filebuf must be able to translate characters one internal character at a time.

264) If encoding() yields -1, then more than max_length() externT elements may be consumed when producing a single internT character, and additional externT elements may appear at the end of a sequence after those that yield the final internT character.

265) Typically these will be characters to return the state to stateT().

§ 28.4.1.4.2
Effects: The effect on the state argument is as if it called `do_in(state, from, from_end, from, to, to+max, to)` for to pointing to a buffer of at least max elements.

Returns: `(from_next-from)` where `from_next` is the largest value in the range `[from, from_end)` such that the sequence of values in the range `[from, from_next)` represents max or fewer valid complete characters of type `internT`. The specialization `codecvt<char, char, mbstate_t>` returns the lesser of max and `(from_end-from)`.

```cpp
int do_max_length() const noexcept;
```

Returns: The maximum value that `do_length(state, from, from_end, 1)` can return for any valid range `[from, from_end)` and `stateT` value `state`. The specialization `codecvt<char, char, mbstate_t>::do_max_length()` returns 1.

28.4.1.5 Class template `codecvt_byname`

```cpp
namespace std {
    template<class internT, class externT, class stateT>
    class codecvt_byname : public codecvt<internT, externT, stateT> {
    public:
        explicit codecvt_byname(const char*, size_t refs = 0);
        explicit codecvt_byname(const string&, size_t refs = 0);
    protected:
        "codecvt_byname();"
    }
}
```

28.4.2 The numeric category

The classes `num_get<>` and `num_put<>` handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.\(^{266}\)

All specifications of member functions for `num_put` and `num_get` in the subclauses of 28.4.2 only apply to the specializations required in Tables 102 and 103 (28.3.1.1.1), namely `num_get<char>`, `num_get<wchar_t>`, `num_get<C, InputIterator>`, `num_put<char>`, `num_put<wchar_t>`, and `num_put<C, OutputIterator>`. These specializations refer to the `ios_base&` argument for formatting specifications (28.4), and to its imbued locale for the `numpunct<>` facet to identify all numeric punctuation preferences, and also for the `ctype<>` facet to perform character classification.

Extractor and inserter members of the standard iostreams use `num_get<>` and `num_put<>` member functions for formatting and parsing numeric values (29.7.4.2.1, 29.7.5.2.1).

28.4.2.1 Class template `num_get`

```cpp
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class num_get : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = InputIterator;

        explicit num_get(size_t refs = 0);

        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, bool& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, long& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, long long& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, unsigned short& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, unsigned int& v) const;
    }
```

\(^{266}\) Parsing "-1" correctly into, e.g., an unsigned short requires that the corresponding member `get()` at least extract the sign before delegating.
The facet `num_get` is used to parse numeric values from an input sequence such as an istream.

### Members

```cpp
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, bool& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned short& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned int& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, float& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, double& val) const;
```
iter_type get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, long double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, void*& val) const;

Returns: do_get(in, end, str, err, val).

28.4.2.1.2 Virtual functions

iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, long double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, unsigned short& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, unsigned int& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, unsigned long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, unsigned long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, float& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str, 
ios_base::iostate& err, void*& val) const;

Effects: Reads characters from in, interpreting them according to str.flags(), use_facet<ctype<charT>>/(loc),
and use_facet<numpunct<charT>>/(loc), where loc is str.getloc().

The details of this operation occur in three stages

(2.1) — Stage 1: Determine a conversion specifier

(2.2) — Stage 2: Extract characters from in and determine a corresponding char value for the format expected
by the conversion specification determined in stage 1.

(2.3) — Stage 3: Store results

The details of the stages are presented below.

Stage 1: The function initializes local variables via
fmtflags flags = str.flags();
fmtflags basefield = (flags & ios_base::basefield);
fmtflags uppercase = (flags & ios_base::uppercase);
fmtflags boolalpha = (flags & ios_base::boolalpha);

For conversion to an integral type, the function determines the integral conversion specifier as indicated
in Table 106. The table is ordered. That is, the first line whose condition is true applies.

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == oct</td>
<td>%o</td>
</tr>
<tr>
<td>basefield == hex</td>
<td>%x</td>
</tr>
<tr>
<td>basefield == 0</td>
<td>%i</td>
</tr>
<tr>
<td>signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversions to a floating-point type the specifier is %g.
For conversions to void* the specifier is %p.
A length modifier is added to the conversion specification, if needed, as indicated in Table 107.
Stage 2: If \( \text{in} == \text{end} \) then stage 2 terminates. Otherwise a \( \text{charT} \) is taken from \( \text{in} \) and local variables are initialized as if by

\[
\text{char\_type} \; \text{ct} = *\text{in};
\]

\[
\text{char} \; \text{c} = \text{src}[\text{find(\text{atoms, atoms + sizeof(src) - 1, ct}) - atoms}];
\]

if \( (\text{ct} == \text{use\_facet\text{\langle numpunct\text{\langle charT\text{\rangle\rangle\text\langle loc\text{\rangle}}}\.\text{decimal\_point()}}) \)

\[
\text{c} = \'.\';
\]

bool discard =

\[
\text{ct} == \text{use\_facet\text{\langle numpunct\text{\langle charT\text{\rangle\rangle\text\langle loc\text{\rangle}}}\.\text{thousands\_sep()}}
\]

\[
&& \text{use\_facet\text{\langle numpunct\text{\langle charT\text{\rangle\rangle\text\langle loc\text{\rangle}}}\.\text{grouping().length()} } != 0;
\]

where the values \( \text{src} \) and \( \text{atoms} \) are defined as if by:

\[
\text{static const char src[\text{sizeof(src)] = } "0123456789abcdefabcdefabcdef++-\";}
\]

\[
\text{char\_type atoms[\text{sizeof(src)]};}
\]

\[
\text{use\_facet\text{\langle type\text{\langle charT\text{\rangle\rangle\text\langle loc\text{\rangle}}}\.\text{widen(src, src + sizeof(src), atoms);}
\]

for this value of \( \text{loc} \).

If \( \text{discard} \) is true, then if \( \text{'}\).\text{'} has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if \( \text{'}\).\text{'} has already been accumulated, the character is discarded and Stage 2 terminates. If it is not discarded, then a check is made to determine if \( \text{c} \) is allowed as the next character of an input field of the conversion specifier returned by Stage 1. If so, it is accumulated.

If the character is either discarded or accumulated then \( \text{in} \) is advanced by \( ++\text{in} \) and processing returns to the beginning of stage 2.

Stage 3: The sequence of \( \text{chars} \) accumulated in stage 2 (the field) is converted to a numeric value by the rules of one of the functions declared in the header \(<\text{cstdlib}>\):

- For a signed integer value, the function \( \text{strtoll} \).
- For an unsigned integer value, the function \( \text{strtoull} \).
- For a float value, the function \( \text{strtof} \).
- For a double value, the function \( \text{strtol} \).
- For a long double value, the function \( \text{stroldl} \).

The numeric value to be stored can be one of:

- zero, if the conversion function does not convert the entire field.
- the most positive (or negative) representable value, if the field to be converted to a signed integer type represents a value too large positive (or negative) to be represented in \( \text{val} \).
- the most positive representable value, if the field to be converted to an unsigned integer type represents a value that cannot be represented in \( \text{val} \).
- the converted value, otherwise.

The resultant numeric value is stored in \( \text{val} \). If the conversion function does not convert the entire field, or if the field represents a value outside the range of representable values, \( \text{ios\_base::failbit} \) is assigned to \( \text{err} \).

4 Digit grouping is checked. That is, the positions of discarded separators is examined for consistency with \( \text{use\_facet\text{\langle numpunct\text{\langle charT\text{\rangle\rangle\text\langle loc\text{\rangle}}}\.\text{grouping()}} \). If they are not consistent then \( \text{ios\_base::failbit} \) is assigned to \( \text{err} \).

5 In any case, if stage 2 processing was terminated by the test for \( \text{in} == \text{end} \) then \( \text{err} \) |= \( \text{ios\_base::eofbit} \) is performed.

\[\section{28.4.2.1.2} \]
iter_type do_get(iter_type in, iter_type end, ios_base& str,
ios_base::iostate& err, bool& val) const;

Effects: If (str.flags()&ios_base::boolalpha) == 0 then input proceeds as it would for a long except
that if a value is being stored into val, the value is determined according to the following: If the value to
be stored is 0 then false is stored. If the value is 1 then true is stored. Otherwise true is stored and
ios_base::failbit is assigned to err.

Otherwise target sequences are determined "as if" by calling the members falsename() and truename() of
the facet obtained by use_facet<numpunct<charT>>(str.getloc()). Successive characters in the range
[in, end) (see 22.2.3) are obtained and matched against corresponding positions in the target sequences only
as necessary to identify a unique match. The input iterator in is compared to end only when necessary to
obtain a character. If a target sequence is uniquely matched, val is set to the corresponding value. Otherwise
false is stored and ios_base::failbit is assigned to err.

The in iterator is always left pointing one position beyond the last character successfully matched. If val is set,
then err is set to str.goodbit; or to str.eofbit if, when seeking another character to match, it is found
that (in == end). If val is not set, then err is set to str.failbit; or to (str.failbit|str.eofbit) if
the reason for the failure was that (in == end). [Example: For targets true: "a" and false: "abb", the
input sequence "a" yields val == true and err == str.eofbit; the input sequence "abc" yields err =
str.failbit, with in ending at the 'c' element. For targets true: "1" and false: "0", the input sequence
"1" yields val == true and err == str.goodbit. For empty targets (""), any input sequence yields err
== str.failbit. — end example]

Returns: in.

28.4.2.2 Class template num_put

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class num_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;
            explicit num_put(size_t refs = 0);
            iter_type put(iter_type s, ios_base& f, char_type fill, bool v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, const void* v) const;
        protected:
            num_put();
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, bool v) const;
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, long v) const;
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, long long v) const;
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, unsigned long v) const;
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, unsigned long long v) const;
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, double v) const;
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, long double v) const;
            virtual iter_type do_put(iter_type s, ios_base& f, char_type fill, const void* v) const;
    };
}

The facet num_put is used to format numeric values to a character sequence such as an ostream.

28.4.2.2.1 Members

iter_type put(iter_type out, ios_base& str, char_type fill, bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, const void* val) const;

Returns: do_put(out, str, fill, val).

28.4.2.2.2 Virtual functions

iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, const void* val) const;

Effects: Writes characters to the sequence out, formatting val as desired. In the following description, loc names a local variable initialized as

locale loc = str.getloc();

The details of this operation occur in several stages:

(2.1) Stage 1: Determine a printf conversion specifier spec and determine the characters that would be printed by printf (29.12) given this conversion specifier for

printf(spec, val)

assuming that the current locale is the "C" locale.

(2.2) Stage 2: Adjust the representation by converting each char determined by stage 1 to a charT using a conversion and values returned by members of use_facet<numpunct<charT>>(loc).

(2.3) Stage 3: Determine where padding is required.

(2.4) Stage 4: Insert the sequence into the out.

Detailed descriptions of each stage follow.

Returns: out.

Stage 1: The first action of stage 1 is to determine a conversion specifier. The tables that describe this determination use the following local variables:

fmtflags flags = str.flags();
fmtflags basefield = (flags & (ios_base::basefield));
fmtflags uppercase = (flags & (ios_base::uppercase));
fmtflags floatfield = (flags & (ios_base::floatfield));
fmtflags showpos = (flags & (ios_base::showpos));
fmtflags showbase = (flags & (ios_base::showbase));
fmtflags showpoint = (flags & (ios_base::showpoint));

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true applies. A line without a condition is the default behavior when none of the earlier lines apply.

For conversion from an integral type other than a character type, the function determines the integral conversion specifier as indicated in Table 108.

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == ios_base::oct</td>
<td>%o</td>
</tr>
<tr>
<td>(basefield == ios_base::hex) &amp;&amp; !uppercase</td>
<td>%x</td>
</tr>
<tr>
<td>(basefield == ios_base::hex)</td>
<td>%X</td>
</tr>
<tr>
<td>for a signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>for an unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

§ 28.4.2.2.2
For conversion from a floating-point type, the function determines the floating-point conversion specifier as indicated in Table 109.

Table 109: Floating-point conversions  

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>floatfield == ios_base::fixed</code></td>
<td><code>%f</code></td>
</tr>
<tr>
<td><code>floatfield == ios_base::scientific &amp;&amp; !uppercase</code></td>
<td><code>%e</code></td>
</tr>
<tr>
<td><code>floatfield == ios_base::scientific</code></td>
<td><code>%E</code></td>
</tr>
<tr>
<td>`floatfield == (ios_base::fixed</td>
<td>ios_base::scientific) &amp;&amp; !uppercase`</td>
</tr>
<tr>
<td>`floatfield == (ios_base::fixed</td>
<td>ios_base::scientific)`</td>
</tr>
<tr>
<td><code>!uppercase</code></td>
<td><code>%g</code></td>
</tr>
<tr>
<td><code>otherwise</code></td>
<td><code>%G</code></td>
</tr>
</tbody>
</table>

For conversions from an integral or floating-point type a length modifier is added to the conversion specifier as indicated in Table 110.

Table 110: Length modifier  

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
<tr>
<td>otherwise</td>
<td>none</td>
</tr>
</tbody>
</table>

The conversion specifier has the following optional additional qualifiers prepended as indicated in Table 111.

Table 111: Numeric conversions  

<table>
<thead>
<tr>
<th>Type(s)</th>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>an integral type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showbase</td>
<td>#</td>
</tr>
<tr>
<td>a floating-point type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showpoint</td>
<td>#</td>
</tr>
</tbody>
</table>

For conversion from a floating-point type, if `floatfield != (ios_base::fixed | ios_base::scientific)`, `str.precision()` is specified as precision in the conversion specification. Otherwise, no precision is specified.

For conversion from `void*` the specifier is `%p`.

The representations at the end of stage 1 consists of the char’s that would be printed by a call of `printf(s, val)` where `s` is the conversion specifier determined above.

**Stage 2:** Any character other than a decimal point(.) is converted to a charT via

```
use_facet<typename charT>(loc).widen(c)
```

A local variable `punct` is initialized via

```
const numpunct<charT>& punct = use_facet<numpunct<charT>>(loc);
```

For arithmetic types, `punct.thousands_sep()` characters are inserted into the sequence as determined by the value returned by `punct.do_grouping()` using the method described in 28.4.3.1.2

Decimal point characters(.) are replaced by `punct.decimal_point()`.

**Stage 3:** A local variable is initialized as

```
fmtflags adjustfield = (flags & (ios_base::adjustfield));
```

The location of any padding\(^{267}\) is determined according to Table 112.

---

\(^{267}\) The conversion specification #0 generates a leading 0 which is not a padding character.
Table 112: Fill padding  

<table>
<thead>
<tr>
<th>State</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield == ios_base::left</td>
<td>pad after</td>
</tr>
<tr>
<td>adjustfield == ios_base::right</td>
<td>pad before</td>
</tr>
<tr>
<td>adjustfield == internal and a sign occurs in the representation</td>
<td>pad after the sign</td>
</tr>
<tr>
<td>adjustfield == internal and representation after stage 1 began with 0x or 0X</td>
<td>pad after x or X</td>
</tr>
<tr>
<td>otherwise</td>
<td>pad before</td>
</tr>
</tbody>
</table>

If str.width() is nonzero and the number of charT’s in the sequence after stage 2 is less than str.width(), then enough fill characters are added to the sequence at the position indicated for padding to bring the length of the sequence to str.width(). str.width(0) is called.

**Stage 4:** The sequence of charT’s at the end of stage 3 are output via

\*out++ = c

iter_type do_put(iter_type out, ios_base& str, char_type fill, bool val) const;

6

Returns: If (str.flags() & ios_base::boolalpha) == 0 returns do_put(out, str, fill, (int)val), otherwise obtains a string s as if by

string_type s =
val ? use_facet<numpunct<charT>>(loc).truename() : use_facet<numpunct<charT>>(loc).falsename();

and then inserts each character c of s into out via \*out++ = c and returns out.

28.4.3 The numeric punctuation facet

28.4.3.1 Class template numpunct

namespace std {
    template<class charT>
    class numpunct : public locale::facet {
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;

            explicit numpunct(size_t refs = 0);
            char_type decimal_point() const;
            char_type thousands_sep() const;
            string grouping() const;
            string_type truename() const;
            string_type falsename() const;

            static locale::id id;

            protected:
                "numpunct"(); // virtual
                virtual char_type do_decimal_point() const;
                virtual char_type do_thousands_sep() const;
                virtual string do_grouping() const;
                virtual string_type do_truename() const; // for bool
                virtual string_type do_falsename() const; // for bool
        }
    }

1 numpunct<> specifies numeric punctuation. The specializations required in Table 102 (28.3.1.1.1), namely numpunct<wchar_t> and numpunct<char>, provide classic "C" numeric formats, i.e., they contain information equivalent to that contained in the "C" locale or their wide character counterparts as if obtained by a call to widen.
The syntax for number formats is as follows, where `digit` represents the radix set specified by the `fmtflags` argument value, and `thousands-sep` and `decimal-point` are the results of corresponding `numpunct<charT>` members. Integer values have the format:

- **intval:**
  - `sign opt units`
  - `sign`: `+` `-`
  - `units`:
    - `digits`
    - `digits thousands-sep units`
  - `digits`:
    - `digit digits_opt`

and floating-point values have:

- **floatval:**
  - `sign opt units fractional_opt exponent_opt`
  - `sign_opt decimal-point digits exponent_opt`
  - `fractional`:
    - `decimal-point digits_opt`
  - `exponent`:
    - `e sign_opt digits`
    - `e E`

where the number of digits between `thousands-seps` is as specified by `do_grouping()`. For parsing, if the `digits` portion contains no thousands-separators, no grouping constraint is applied.

### 28.4.3.1.1 Members

- `char_type decimal_point() const;`
  - **Returns:** `do_decimal_point()`.

- `char_type thousands_sep() const;`
  - **Returns:** `do_thousands_sep()`.

- `string grouping() const;`
  - **Returns:** `do_grouping()`.

- `string_type truename() const;`  
  - **Returns:** `do_truename()` or `do_falsename()`, respectively.

### 28.4.3.1.2 Virtual functions

- `char_type do_decimal_point() const;`
  - **Returns:** A character for use as the decimal radix separator. The required specializations return `.` or `L.`.

- `char_type do_thousands_sep() const;`
  - **Returns:** A character for use as the digit group separator. The required specializations return `.` or `L.`.

- `string do_grouping() const;`
  - **Returns:** A string `vec` used as a vector of integer values, in which each element `vec[i]` represents the number of digits in the group at position `i`, starting with position 0 as the rightmost group. If `vec.size() <= i`, the number is the same as group `(i - 1)`; if `(i < 0 || vec[i] <= 0 || vec[i] == CHAR_MAX)`, the size of the digit group is unlimited.

---

268 Thus, the string `"\003"` specifies groups of 3 digits each, and `"3"` probably indicates groups of 51 (!) digits each, because 51 is the ASCII value of `"3"`. 
The required specializations return the empty string, indicating no grouping.

string_type do_truename() const;
string_type do_falsename() const;

Returns: A string representing the name of the boolean value true or false, respectively.

In the base class implementation these names are “true” and “false”, or L“true” and L“false”.

28.4.3.2 Class template numpunct_byname

namespace std {
  template<class charT>
  class numpunct_byname : public numpunct<charT> {
    // this class is specialized for char and wchar_t.
    public:
      using char_type = charT;
      using string_type = basic_string<charT>;
      explicit numpunct_byname(const char*, size_t refs = 0);
      explicit numpunct_byname(const string&, size_t refs = 0);
    protected:
      ~numpunct_byname();
  };
}

28.4.4 The collate category

28.4.4.1 Class template collate

namespace std {
  template<class charT>
  class collate : public locale::facet {
    public:
      using char_type = charT;
      using string_type = basic_string<charT>;
      explicit collate(size_trefs = 0);
      int compare(const charT* low1, const charT* high1,
                  const charT* low2, const charT* high2) const;
      string_type transform(const charT* low, const charT* high) const;
      long hash(const charT* low, const charT* high) const;
      static locale::id id;
    protected:
      ~collate();
      virtual int do_compare(const charT* low1, const charT* high1,
                             const charT* low2, const charT* high2) const;
      virtual string_type do_transform(const charT* low, const charT* high) const;
      virtual long do_hash (const charT* low, const charT* high) const;
  };
}

The class collate<charT> provides features for use in the collation (comparison) and hashing of strings. A locale member function template, operator(), uses the collate facet to allow a locale to act directly as the predicate argument for standard algorithms (Clause 25) and containers operating on strings. The specializations required in Table 102 (28.3.1.1.1), namely collate<char> and collate<wchar_t>, apply lexicographic ordering (25.8.10).

Each function compares a string of characters *p in the range [low, high).

28.4.4.1.1 Members

int compare(const charT* low1, const charT* high1,
            const charT* low2, const charT* high2) const;

Returns: do_compare(low1, high1, low2, high2).
string_type transform(const charT* low, const charT* high) const;

Returns: do_transform(low, high).

long hash(const charT* low, const charT* high) const;

Returns: do_hash(low, high).

28.4.4.1.2 Virtual functions

int do_compare(const charT* low1, const charT* high1,
               const charT* low2, const charT* high2) const;

Returns: 1 if the first string is greater than the second, -1 if less, zero otherwise. The specializations required in Table 102 (28.3.1.1.1), namely collate<char> and collate<wchar_t>, implement a lexicographical comparison (25.8.10).

string_type do_transform(const charT* low, const charT* high) const;

Returns: A basic_string<charT> value that, compared lexicographically with the result of calling transform() on another string, yields the same result as calling do_compare() on the same two strings.\[^{269}\]

long do_hash(const charT* low, const charT* high) const;

Returns: An integer value equal to the result of calling hash() on any other string for which do_compare() returns 0 (equal) when passed the two strings. [Note: The probability that the result equals that for another string which does not compare equal should be very small, approaching (1.0/numeric_limits<unsigned long>::max()). — end note]

28.4.4.2 Class template collate_byname

namespace std {
    template<class charT>
    class collate_byname : public collate<charT> {
        public:
            using string_type = basic_string<charT>;

            explicit collate_byname(const char*, size_t refs = 0);
            explicit collate_byname(const string&, size_t refs = 0);

            protected:
                ~collate_byname();
            }
    }

28.4.5 The time category

Templates time_get<charT, InputIterator> and time_put<charT, OutputIterator> provide date and time formatting and parsing. All specifications of member functions for time_put and time_get in the subclasses of 28.4.5 only apply to the specializations required in Tables 102 and 103 (28.3.1.1.1). Their members use their ios_base&, ios_base::iostate&, and fill arguments as described in 28.4, and the ctype<> facet, to determine formatting details.

28.4.5.1 Class template time_get

namespace std {
    class time_base {
        public:
            enum dateorder { no_order, dmy, mdy, ymd, ydm };
    }

    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class time_get : public locale::facet, public time_base {
        public:
            using char_type = charT;
            using iter_type = InputIterator;

\[^{269}\] This function is useful when one string is being compared to many other strings.
explicit time_get(size_t refs = 0);

dateorder date_order() const { return do_date_order(); }
iter_type get_time(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
iter_type get_date(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
iter_type get_weekday(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
iter_type get_monthname(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
iter_type get_year(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
iter_type get(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
iter_type get(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t, const char_type* fmt,
    const char_type* fmtend) const;

static locale::id id;

protected:
    ~time_get();
    virtual dateorder do_date_order() const;
    virtual iter_type do_get_time(iter_type s, iter_type end, ios_base& str,
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_date(iter_type s, iter_type end, ios_base& str,
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str,
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str,
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_year(iter_type s, iter_type end, ios_base& str,
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get(iter_type s, iter_type end, ios_base& str,
        ios_base::iostate& err, tm* t, char format, char modifier) const;
};

1 time_get is used to parse a character sequence, extracting components of a time or date into a struct tm object. Each get member parses a format as produced by a corresponding format specifier to time_put<>::put. If the sequence being parsed matches the correct format, the corresponding members of the struct tm argument are set to the values used to produce the sequence; otherwise either an error is reported or unspecified values are assigned.270

2 If the end iterator is reached during parsing by any of the get() member functions, the member sets ios_base::eof-bit in err.

28.4.5.1.1 Members

[locale.time.get.members]
dateorder date_order() const;
1    Returns: do_date_order().
iter_type get_time(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
2    Returns: do_get_time(s, end, str, err, t).
iter_type get_date(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
3    Returns: do_get_date(s, end, str, err, t).

270 In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.
iter_type get_weekday(iter_type s, iter_type end, ios_base& str,  
    ios_base::iostate& err, tm* t) const;

iter_type get_monthname(iter_type s, iter_type end, ios_base& str,  
    ios_base::iostate& err, tm* t) const;

Returns: do_get_weekday(s, end, str, err, t) or do_get_monthname(s, end, str, err, t).

iter_type get_year(iter_type s, iter_type end, ios_base& str,  
    ios_base::iostate& err, tm* t) const;

Returns: do_get_year(s, end, str, err, t).

iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err,  
    tm* t, char format, char modifier = 0) const;

Returns: do_get(s, end, f, err, t, format, modifier).

iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err,  
    tm* t, const char_type* fmt, const char_type* fmtend) const;

Preconditions: [fmt, fmtend) is a valid range.

Effects: The function starts by evaluating err = ios_base::goodbit. It then enters a loop, reading zero or  
more characters from s at each iteration. Unless otherwise specified below, the loop terminates when the first  
of the following conditions holds:

- The expression fmt == fmtend evaluates to true.
- The expression err == ios_base::goodbit evaluates to false.
- The expression s == end evaluates to true, in which case the function evaluates err = ios_base::eofbit  
  | ios_base::failbit.
- The next element of fmt is equal to ‘%’, optionally followed by a modifier character, followed by a  
  conversion specifier character, format, together forming a conversion specification valid for the ISO/IEC  
9945 function strftime. If the number of elements in the range [fmt, fmtend) is not sufficient to  
unambiguously determine whether the conversion specification is complete and valid, the function  
evaluates err = ios_base::failbit. Otherwise, the function evaluates s = do_get(s, end, f,  
err, t, format, modifier), where the value of modifier is ‘\0’ when the optional modifier is  
absent from the conversion specification. If err == ios_base::goodbit holds after the evaluation of  
the expression, the function increments fmt to point just past the end of the conversion specification  
and continues looping.

- The expression isspace(*fmt, f.getloc()) evaluates to true, in which case the function first incre-
ments fmt until fmt == fmtend || !isspace(*fmt, f.getloc()) evaluates to true, then advances  
s until s == end || !isspace(*s, f.getloc()) is true, and finally resumes looping.
- The next character read from s matches the element pointed to by fmt in a case-insensitive comparison, in  
which case the function evaluates ++fmt, ++s and continues looping. Otherwise, the function evaluates  
err = ios_base::failbit.

[Note: The function uses the ctype<charT> facet installed in f’s locale to determine valid whitespace characters.  
It is unspecified by what means the function performs case-insensitive comparison or whether multi-character  
sequences are considered while doing so. – end note]

Returns: s.

28.4.5.1.2 Virtual functions

[locale.time.get.virtuals]

dateorder do_date_order() const;

Returns: An enumeration value indicating the preferred order of components for those date formats that are  
composed of day, month, and year.® Returns no_order if the date format specified by ‘x’ contains other  
variable components (e.g., Julian day, week number, week day).

® This function is intended as a convenience only, for common formats, and may return no_order in valid locales.

§ 28.4.5.1.2
iter_type do_get_time(iter_type s, iter_type end, ios_base& str,  
  ios_base::iostate& err, tm* t) const;

*Effects:* Reads characters starting at *s* until it has extracted those *struct tm* members, and remaining format  
characters, used by *time_put<>::put* to produce the format specified by "%H:%M:%S", or until it encounters  
an error or end of sequence.

*Returns:* An iterator pointing immediately beyond the last character recognized as possibly part of a valid time.

iter_type do_get_date(iter_type s, iter_type end, ios_base& str,  
  ios_base::iostate& err, tm* t) const;

*Effects:* Reads characters starting at *s* until it has extracted those *struct tm* members and remaining format  
characters used by *time_put<>::put* to produce one of the following formats, or until it encounters an error.  
The format depends on the value returned by *date_order()* as shown in Table 113.

Table 113: do_get_date effects  

<table>
<thead>
<tr>
<th>date_order()</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>no_order</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>dmy</td>
<td>&quot;%d%m%y&quot;</td>
</tr>
<tr>
<td>mdy</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>ymd</td>
<td>&quot;%y%m%d&quot;</td>
</tr>
<tr>
<td>ydm</td>
<td>&quot;%y%d%m&quot;</td>
</tr>
</tbody>
</table>

An implementation may also accept additional implementation-defined formats.

*Returns:* An iterator pointing immediately beyond the last character recognized as possibly part of a valid date.

iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str,  
  ios_base::iostate& err, tm* t) const;
iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str,  
  ios_base::iostate& err, tm* t) const;

*Effects:* Reads characters starting at *s* until it has extracted the (perhaps abbreviated) name of a weekday or  
month. If it finds an abbreviation that is followed by characters that could match a full name, it continues  
reading until it matches the full name or fails. It sets the appropriate *struct tm* member accordingly.

*Returns:* An iterator pointing immediately beyond the last character recognized as part of a valid name.

iter_type do_get_year(iter_type s, iter_type end, ios_base& str,  
  ios_base::iostate& err, tm* t) const;

*Effects:* Reads characters starting at *s* until it has extracted an unambiguous year identifier. It is implementation-  
defined whether two-digit year numbers are accepted, and (if so) what century they are assumed to lie in. Sets  
the *t->tm_year* member accordingly.

*Returns:* An iterator pointing immediately beyond the last character recognized as part of a valid year identifier.

iter_type do_get(iter_type s, iter_type end, ios_base& f,  
  ios_base::iostate& err, tm* t, char format, char modifier) const;

*Preconditions:* *t* points to an object.

*Effects:* The function starts by evaluating *err = ios_base::goodbit*. It then reads characters starting at  
*s* until it encounters an error, or until it has extracted and assigned those *struct tm* members, and any  
remaining format characters, corresponding to a conversion directive appropriate for the ISO/IEC 9945 function  
strptime, formed by concatenating '%', the modifier character, when non-NUL, and the format character.  
When the concatenation fails to yield a complete valid directive the function leaves the object pointed to by *t*  
unchanged and evaluates *err |= ios_base::failbit*. When *s == end* evaluates to true after reading a  
character the function evaluates *err |= ios_base::eofbit*.

For complex conversion directives such as '%c, %x, or %X, or directives that involve the optional modifiers E or  
O, when the function is unable to unambiguously determine some or all *struct tm* members from the input  
sequence [*s, end*], it evaluates *err |= ios_base::eofbit*. In such cases the values of those *struct tm*  
members are unspecified and may be outside their valid range.

§ 28.4.5.1.2
Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid input sequence for the given format and modifier.

Remarks: It is unspecified whether multiple calls to do_get() with the address of the same struct tm object will update the current contents of the object or simply overwrite its members. Portable programs should zero out the object before invoking the function.

### 28.4.5.2 Class template time_getbyname

```cpp
namespace std {
    template< class charT, class InputIterator = istreambuf_iterator<charT> >
    class time_getbyname : public time_get<charT, InputIterator> {
public:
    using dateorder = time_base::dateorder;
    using iter_type = InputIterator;

    explicit time_getbyname(const char*, size_t refs = 0);
    explicit time_getbyname(const string&, size_t refs = 0);

    protected:
        ~time_getbyname();
    }
}
```

### 28.4.5.3 Class template time_put

```cpp
namespace std {
    template< class charT, class OutputIterator = ostreambuf_iterator<charT> >
    class time_put : public locale::facet {
public:
    using char_type = charT;
    using iter_type = OutputIterator;

    explicit time_put(size_t refs = 0);

    // the following is implemented in terms of other member functions.
    iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb,
                  const charT* pattern, const charT* pat_end) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  const tm* tmb, char format, char modifier = 0) const;

    static locale::id id;

    protected:
        ~time_put();
        virtual iter_type do_put(iter_type s, ios_base& f, char_type fill,
                                  const tm* t, char format, char modifier) const;
    }
}
```

### 28.4.5.3.1 Members

```cpp
iter_type put(iter_type s, ios_base& f, char_type fill, const tm* t,
              const charT* pattern, const charT* pat_end) const;
iter_type put(iter_type s, ios_base& f, char_type fill, const tm* t,
              const charT* pattern, const charT* pat_end) const;
```

Effects: The first form steps through the sequence from pattern to pat_end, identifying characters that are part of a format sequence. Each character that is not part of a format sequence is written to s immediately, and each format sequence, as it is identified, results in a call to do_put; thus, format elements and other characters are interleaved in the output in the order in which they appear in the pattern. Format sequences are identified by converting each character c to a char value as if by ct.narrow(c, 0), where ct is a reference to ctype<charT> obtained from f.getloc(). The first character of each sequence is equal to ’%', followed by an optional modifier character mod and a format specifier character spec as defined for the function.

---

272) Although the C programming language defines no modifiers, most vendors do.
strftime. If no modifier character is present, mod is zero. For each valid format sequence identified, calls 
do_put(s, str, fill, t, spec, mod).
The second form calls do_put(s, str, fill, t, format, modifier).

[Note: The fill argument may be used in the implementation-defined formats or by derivations. A space character
is a reasonable default for this argument. — end note]

Returns: An iterator pointing immediately after the last character produced.

### 28.4.5.3.2 Virtual functions

```cpp
ter_type do_put(iter_type s, ios_base&, char_type fill, const tm* t,
    char format, char modifier) const;
```

Effects: Formats the contents of the parameter t into characters placed on the output sequence s. Formatting is
controlled by the parameters format and modifier, interpreted identically as the format specifiers in the string
argument to the standard library function strftime(). except that the sequence of characters produced for
those specifiers that are described as depending on the C locale are instead implementation-defined.

Returns: An iterator pointing immediately after the last character produced. [Note: The fill argument may be
used in the implementation-defined formats or by derivations. A space character is a reasonable default for
this argument. — end note]

### 28.4.5.4 Class template time_put_byname

```cpp
namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class time_put_byname : public time_put<charT, OutputIterator> {
    public:
        using char_type = charT;
        using iter_type = OutputIterator;

        explicit time_put_byname(const char*, size_t refs = 0);
        explicit time_put_byname(const string&, size_t refs = 0);

    protected:
        "time_put_byname();
    };
}
```

### 28.4.6 The monetary category

These templates handle monetary formats. A template parameter indicates whether local or international monetary
formats are to be used.

All specifications of member functions for money_put and money_get in the subclauses of 28.4.6 only apply to the
specializations required in Tables 102 and 103 (28.3.1.1.1). Their members use their ios_base&, ios_base::iostate&,
and fill arguments as described in 28.4, and the moneypunct<> and ctype<> facets, to determine formatting
details.

### 28.4.6.1 Class template money_get

```cpp
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class money_get : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = InputIterator;
        using string_type = basic_string<charT>;

        explicit money_get(size_t refs = 0);
    }
}
```
iter_type get(iter_type s, iter_type end, bool intl,
    ios_base& f, ios_base::iostate& err,
    long double& units) const;
iter_type get(iter_type s, iter_type end, bool intl,
    ios_base& f, ios_base::iostate& err,
    string_type& digits) const;

static locale::id id;

protected:

~money_get();
virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
    ios_base::iostate& err, long double& units) const;
virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
    ios_base::iostate& err, string_type& digits) const;

};

28.4.6.1.1 Members

iter_type get(iter_type s, iter_type end, bool intl, ios_base& f,
    ios_base::iostate& err, long double& quant) const;
iter_type get(iter_type s, iter_type end, bool intl, ios_base& f,
    ios_base::iostate& err, string_type& quant) const;

1 Returns: do_get(s, end, intl, f, err, quant).

28.4.6.1.2 Virtual functions

iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& str,
    ios_base::iostate& err, long double& units) const;
iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& str,
    ios_base::iostate& err, string_type& digits) const;

1 Effects: Reads characters from s to parse and construct a monetary value according to the format specified by a moneypunct<
    charT, Intl> facet reference mp and the character mapping specified by a ctype<
    charT> facet reference ct obtained from the locale returned by str.getloc(), and str.flags(). If a valid sequence is rec-
    ognized, does not change err; otherwise, sets err to (err|str.failbit), or (err|str.failbit|str.eof-
    bit) if no more characters are available, and does not change units or digits. Uses the pattern returned by mp.neg_format() to parse all values. The result is returned as an integral value stored in units or as a sequence of digits possibly preceded by a minus sign (as produced by ct.widen(c) where c is '−' or in the range from '0' through '9' (inclusive)) stored in digits. [Example: The sequence $1,056.23 in a common United States locale would yield, for units, 105623, or, for digits, "105623". — end example] If mp.grouping() indicates that no thousands separators are permitted, any such characters are not read, and parsing is terminated at the point where they first appear. Otherwise, thousands separators are optional; if present, they are checked for correct placement only after all format components have been read.

Where money_base::space or money_base::none appears as the last element in the format pattern, no white space is consumed. Otherwise, where money_base::space appears in any of the initial elements of the format pattern, at least one white space character is required. Where money_base::none appears in any of the initial elements of the format pattern, white space is allowed but not required. If (str.flags() & str.showbase) is false, the currency symbol is optional and is consumed only if other characters are needed to complete the format; otherwise, the currency symbol is required.

3 If the first character (if any) in the string pos returned by mp.positive_sign() or the string neg returned by mp.negative_sign() is recognized in the position indicated by sign in the format pattern, it is consumed and any remaining characters in the string are required after all the other format components. [Example: If showbase is off, then for a neg value of "(" and a currency symbol of "L", in "(100 L)" the "L" is consumed; but if neg is ",", the "L" in "-100 L" is not consumed. — end example] If pos or neg is empty, the sign component is optional, and if no sign is detected, the result is given the sign that corresponds to the source of the empty string. Otherwise, the character in the indicated position must match the first character of pos or neg, and the result is given the corresponding sign. If the first character of pos is equal to the first character of neg, or if both strings are empty, the result is given a positive sign.
Digits in the numeric monetary component are extracted and placed in digits, or into a character buffer buf1 for conversion to produce a value for units, in the order in which they appear, preceded by a minus sign if and only if the result is negative. The value units is produced as if by

```cpp
for (int i = 0; i < n; ++i)
    buf2[i] = src[find(atoms, atoms+sizeof(src), buf1[i]) - atoms];
buf2[n] = 0;
sscanf(buf2, "%Lf", &units);
```

where n is the number of characters placed in buf1, buf2 is a character buffer, and the values src and atoms are defined as if by

```cpp
static const char src[] = "0123456789-";
charT atoms[sizeof(src)];
ct.widen(src, src + sizeof(src) - 1, atoms);
```

**Returns:** An iterator pointing immediately beyond the last character recognized as part of a valid monetary quantity.

### Class template `money_put` [locale.money.put]

```cpp
namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class money_put : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = OutputIterator;
        using string_type = basic_string<charT>;
        explicit money_put(size_t refs = 0);
        iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, long double units) const;
        iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, const string_type& digits) const;
        static locale::id id;
    protected:
        ~money_put();
        virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill, long double units) const;
        virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill, const string_type& digits) const;
    };
}
```

#### Members [locale.money.put.members]

- `iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, long double quant) const`;
- `iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, const string_type& quant) const`;

**Returns:** `do_put(s, intl, f, loc, quant)`.

#### Virtual functions [locale.money.put.virtuals]

- `iter_type do_put(iter_type s, bool intl, ios_base& str, char_type fill, long double units) const`;
- `iter_type do_put(iter_type s, bool intl, ios_base& str, char_type fill, const string_type& digits) const`;

**Effects:** Writes characters to s according to the format specified by a `moneypunct<charT, Intl>` facet reference mp and the character mapping specified by a `ctype<charT>` facet reference ct obtained from the locale returned by `str.getloc()` and `str.flags()`. The argument units is transformed into a sequence of wide characters as if by

```cpp
ct.widen(buf1, buf1 + sprintf(buf1, "%.0Lf", units), buf2)
```

275) The semantics here are different from `ct.narrow`.  

§ 28.4.6.2.2 1321
for character buffers buf1 and buf2. If the first character in digits or buf2 is equal to \texttt{ct.widen('\-')}, then the pattern used for formatting is the result of \texttt{mp.neg_format()}; otherwise the pattern is the result of \texttt{mp.pos_format()}. Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in digits or buf2. In digits, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to \texttt{ct}) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls \texttt{str.width(0)}.

Returns: An iterator pointing immediately after the last character produced.

Remarks: The currency symbol is generated if and only if (\texttt{str.flags() & str.showbase}) is nonzero. If the number of characters generated for the specified format is less than the value returned by \texttt{str.width()} on entry to the function, then copies of \texttt{fill} are inserted as necessary to pad to the specified width. For the value \texttt{af} equal to (\texttt{str.flags() & str.adjustfield}), if (\texttt{af == str.internal}) is true, the fill characters are placed where none or space appears in the formatting pattern; otherwise if (\texttt{af == str.left}) is true, they are placed after the other characters; otherwise, they are placed before the other characters. [Note: It is possible, with some combinations of format patterns and flag values, to produce output that cannot be parsed using \texttt{num_get<>::get}. — end note]

### 28.4.6.3 Class template \texttt{moneypunct}

namespace std {
    class money_base {
    public:
        enum part { none, space, symbol, sign, value };
        struct pattern { char field[4]; };
    }

template<class charT, bool International = false>
    class moneypunct : public locale::facet, public money_base {
    public:
        using char_type = charT;
        using string_type = basic_string<charT>;

        explicit moneypunct(size_t refs = 0);

        charT decimal_point() const;
        charT thousands_sep() const;
        string grouping() const;
        string_type curr_symbol() const;
        string_type positive_sign() const;
        string_type negative_sign() const;
        int frac_digits() const;
        pattern pos_format() const;
        pattern neg_format() const;

        static locale::id id;
        static const bool intl = International;

    protected:
        moneypunct();
        virtual charT do_decimal_point() const;
        virtual charT do_thousands_sep() const;
        virtual string do_grouping() const;
        virtual string_type do_curr_symbol() const;
        virtual string_type do_positive_sign() const;
        virtual string_type do_negative_sign() const;
        virtual int do_frac_digits() const;
        virtual pattern do_pos_format() const;
        virtual pattern do_neg_format() const;
    }
}

The \texttt{moneypunct<>} facet defines monetary formatting parameters used by \texttt{money_get<>} and \texttt{money_put<>}. A monetary format is a sequence of four components, specified by a pattern value \(p\), such that the part value...
static_cast<part>(p.field[i]) determines the \texttt{i}th component of the format\textsuperscript{276} in the field member of a pattern object, each value \texttt{symbol}, \texttt{sign}, \texttt{value}, and either \texttt{space} or \texttt{none} appears exactly once. The value \texttt{none}, if present, is not first; the value \texttt{space}, if present, is neither first nor last.

Where \texttt{none} or \texttt{space} appears, white space is permitted in the format, except where \texttt{none} appears at the end, in which case no white space is permitted. The value \texttt{space} indicates that at least one space is required at that position. Where \texttt{symbol} appears, the sequence of characters returned by \texttt{curr_symbol()} is permitted, and can be required. Where \texttt{sign} appears, the first (if any) of the sequence of characters returned by \texttt{positive_sign()} or \texttt{negative_sign()} (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where \texttt{value} appears, the absolute numeric monetary value is required.

The format of the numeric monetary value is a decimal number:

\begin{verbatim}
value:
  units fractional_opt
decimal-point digits
fractional:
decimal-point digits_opt
\end{verbatim}

if \texttt{frac_digits()} returns a positive value, or

\begin{verbatim}
value:
  units
\end{verbatim}

otherwise. The symbol \texttt{decimal-point} indicates the character returned by \texttt{decimal_point()}. The other symbols are defined as follows:

\begin{verbatim}
units:
digits
digits thousands-sep units
digits:
adigit digits_opt
\end{verbatim}

In the syntax specification, the symbol \texttt{adigit} is any of the values \texttt{ct.widen(c)} for \texttt{c} in the range \texttt{'}0' through \texttt{'}9' (inclusive) and \texttt{ct} is a reference of type \texttt{const charT&} obtained as described in the definitions of \texttt{money_get<>} and \texttt{money_put<>.} The symbol \texttt{thousands-sep} is the character returned by \texttt{thousands_sep()}. The space character used is the value \texttt{ct.widen(' ')}.

The placement of thousands-separator characters (if any) is determined by the value returned by \texttt{grouping()}, defined identically as the member \texttt{numpunct<>::do_grouping()}.

\subsection{Members}[[locale.moneypunct.members]]

\begin{verbatim}
charT decimal_point() const;
charT thousands_sep() const;
string grouping() const;
string_type curr_symbol() const;
string_type positive_sign() const;
string_type negative_sign() const;
int frac_digits() const;
pattern pos_format() const;
pattern neg_format() const;
\end{verbatim}

1 Each of these functions \texttt{F} returns the result of calling the corresponding virtual member function \texttt{do_F()}.

\subsection{Virtual functions}[[locale.moneypunct.virtuals]]

\begin{verbatim}
charT do_decimal_point() const;
\end{verbatim}

1 Returns: The radix separator to use in case \texttt{do_frac_digits()} is greater than zero.\textsuperscript{277}

\textsuperscript{276}An array of \texttt{char}, rather than an array of \texttt{part}, is specified for \texttt{pattern::field} purely for efficiency.

\textsuperscript{277}In common U.S. locales this is \texttt{'.'}.
charT do_thousands_sep() const;

Returns: The digit group separator to use in case do_grouping() specifies a digit grouping pattern.

string do_grouping() const;

Returns: A pattern defined identically as, but not necessarily equal to, the result of numpunct<charT>::do_grouping().

string_type do_curr_symbol() const;

Returns: A string to use as the currency identifier symbol. [Note: For specializations where the second template parameter is true, this is typically four characters long: a three-letter code as specified by ISO 4217 followed by a space. — end note]

string_type do_positive_sign() const;

string_type do_negative_sign() const;

Returns: do_positive_sign() returns the string to use to indicate a positive monetary value; do_negative_sign() returns the string to use to indicate a negative value.

int do_frac_digits() const;

Returns: The number of digits after the decimal radix separator, if any.

pattern do_pos_format() const;
pattern do_neg_format() const;

Returns: The specializations required in Table 103 (28.3.1.1.1), namely

- moneypunct<char>,
- moneypunct<wchar_t>,
- moneypunct<char, true>, and
- moneypunct<wchar_t, true>,

return an object of type pattern initialized to { symbol, sign, none, value }.

28.4.6.4 Class template moneypunct_byname

namespace std {
    template<class charT, bool Intl = false>
    class moneypunct_byname : public moneypunct<charT, Intl> {
        public:
            using pattern = money_base::pattern;
            using string_type = basic_string<charT>;

            explicit moneypunct_byname(const char*, size_t refs = 0);
            explicit moneypunct_byname(const string&, size_t refs = 0);

            protected:
                ~moneypunct_byname();
        }
    }

28.4.7 The message retrieval category

Class messages<charT> implements retrieval of strings from message catalogs.

28.4.7.1 Class template messages

namespace std {
    class messages_base {
        public:
            using catalog = unspecified signed integer type;
    };

---

278) In common U.S. locales this is ','.
279) To specify grouping by 3s, the value is "\003" not "3".
280) This is usually the empty string.
281) In common U.S. locales, this is 2.
282) Note that the international symbol returned by do_curr_symbol() usually contains a space, itself; for example, "USD ".

§ 28.4.7.1
template<class charT>
class messages : public locale::facet, public messages_base {
public:
    using char_type = charT;
    using string_type = basic_string<charT>;

    explicit messages(size_t refs = 0);
    catalog open(const string& fn, const locale&) const;
    string_type get(catalog c, int set, int msgid,
                    const string_type& dfault) const;
    void close(catalog c) const;

    static locale::id id;
}

protected:
    ~messages();
    virtual catalog do_open(const string& name, const locale& loc) const;
    virtual string_type do_get(catalog c, int set, int msgid,
                               const string_type& dfault) const;
    virtual void do_close(catalog c) const;
};

1 Values of type messages_base::catalog usable as arguments to members get and close can be obtained only by calling member open.

28.4.7.1.1 Members

catalog open(const string& name, const locale& loc) const;
1 Returns: do_open(name, loc).

string_type get(catalog cat, int set, int msgid, const string_type& dfault) const;
2 Returns: do_get(cat, set, msgid, dfault).

void close(catalog cat) const;
3 Effects: Calls do_close(cat).

28.4.7.1.2 Virtual functions

catalog do_open(const string& name, const locale& loc) const;
1 Returns: A value that may be passed to get() to retrieve a message from the message catalog identified by
the string name according to an implementation-defined mapping. The result can be used until it is passed to
close().
2 Returns a value less than 0 if no such catalog can be opened.
3 Remarks: The locale argument loc is used for character set code conversion when retrieving messages, if
needed.

string_type do_get(catalog cat, int set, int msgid, const string_type& dfault) const;
4 Preconditions: cat is a catalog obtained from open() and not yet closed.
5 Returns: A message identified by arguments set, msgid, and dfault, according to an implementation-defined
mapping. If no such message can be found, returns dfault.

void do_close(catalog cat) const;
6 Preconditions: cat is a catalog obtained from open() and not yet closed.
7 Effects: Releases unspecified resources associated with cat.
8 Remarks: The limit on such resources, if any, is implementation-defined.
28.4.7.2 **Class template** messagesbyname

```cpp
namespace std {
    template<class charT>
    class messagesbyname : public messages<charT> {
        public:
            using catalog = messages_base::catalog;
            using string_type = basic_string<charT>;

            explicit messagesbyname(const char*, size_t refs = 0);
            explicit messagesbyname(const string&, size_t refs = 0);

            protected:
                ~messagesbyname();
    }
}
```

28.5 **C library locales**

28.5.1 **Header** <clocale> [c.locales]

```cpp
namespace std {
    struct lconv;
    char* setlocale(int category, const char* locale);
    lconv* localeconv();
}
```

# define NULL see 17.2.3
# define LC_ALL see below
# define LC_COLLATE see below
# define LC_CTYPE see below
# define LC_MONETARY see below
# define LC_NUMERIC see below
# define LC_TIME see below

1 The contents and meaning of the header <clocale> are the same as the C standard library header <locale.h>.

2 Calls to the function setlocale may introduce a data race (16.5.5.10) with other calls to setlocale or with calls to the functions listed in Table 114.

See also: ISO C 7.11

§ 28.5.1 1326
29 Input/output library

29.1 General

This Clause describes components that C++ programs may use to perform input/output operations.

The following subclauses describe requirements for stream parameters, and components for forward declarations of iostreams, predefined iostreams objects, base iostreams classes, stream buffering, stream formatting and manipulators, string streams, and file streams, as summarized in Table 115.

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header</th>

</tr>
<tr>
<td>29.9</td>
<td>File streams</td>
</tr>
<tr>
<td>29.10</td>
<td>Synchronized output streams</td>
</tr>
<tr>
<td>29.11</td>
<td>File systems</td>
</tr>
<tr>
<td>29.12</td>
<td>C library files</td>
</tr>
</tbody>
</table>

[Note: Figure 7 illustrates relationships among various types described in this Clause. A line from A to B indicates that A is an alias (e.g., a typedef) for B or that A is defined in terms of B.]

--- end note ---

29.2 Iostreams requirements

29.2.1 Imbue limitations

No function described in Clause 29 except for ios_base::imbue and basic_filebuf::pubimbue causes any instance of basic_ios::imbue or basic_streambuf::imbue to be called. If any user function called from a function declared in Clause 29 or as an overriding virtual function of any class declared in Clause 29 calls imbue, the behavior is undefined.
29.2.2 Positioning type limitations [iostreams.limits.pos]

1. The classes of Clause 29 with template arguments charT and traits behave as described if traits::pos_type and traits::off_type are streampos and streamoff respectively. Except as noted explicitly below, their behavior when traits::pos_type and traits::off_type are other types is implementation-defined.

2. In the classes of Clause 29, a template parameter with name charT represents a member of the set of types containing char, wchar_t, and any other implementation-defined character types that meet the requirements for a character on which any of the iostream components can be instantiated.

29.2.3 Thread safety [iostreams.threadsafety]

1. Concurrent access to a stream object (29.8, 29.9), stream buffer object (29.6), or C Library stream (29.12) by multiple threads may result in a data race (6.9.2) unless otherwise specified (29.4). [Note: Data races result in undefined behavior (6.9.2). — end note]

2. If one thread makes a library call a that writes a value to a stream and, as a result, another thread reads this value from the stream through a library call b such that this does not result in a data race, then a’s write synchronizes with b’s read.

29.3 Forward declarations [iostream.forward]

29.3.1 Header <iosfwd> synopsis [iosfwd.syn]

```cpp
namespace std {
    template<class charT> struct char_traits;
    template<> struct char_traits<char>;
    template<> struct char_traits<char8_t>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;
    template<class T> class allocator;

    template<class charT, class traits = char_traits<charT>>
        class basic_ion;
    template<class charT, class traits = char_traits<charT>>
        class basic_streambuf;
    template<class charT, class traits = char_traits<charT>>
        class basic_istream;
    template<class charT, class traits = char_traits<charT>>
        class basic_ostream;
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
        class basic_stringbuf;
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
        class basic_istringstream;
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
        class basic_ostringstream;
    template<class charT, class traits = char_traits<charT>>
        class basic_filebuf;
    template<class charT, class traits = char_traits<charT>>
        class basic_ifstream;
    template<class charT, class traits = char_traits<charT>>
        class basic_ofstream;
    template<class charT, class traits = char_traits<charT>>
        class basic_fstream;
}
```

§ 29.3.1 1328
template<class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_syncbuf;
template<class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_osyncstream;
template<class charT, class traits = char_traits<charT>>

template<class state> class fpos;
using streampos = fpos<char_traits<char>::state_type>;
using wstreampos = fpos<char_traits<wchar_t>::state_type>;
using u8streampos = fpos<char_traits<char8_t>::state_type>;
using u16streampos = fpos<char_traits<char16_t>::state_type>;
using u32streampos = fpos<char_traits<char32_t>::state_type>;
}

1 Default template arguments are described as appearing both in `<iosfwd>` and in the synopsis of other headers but it
is well-formed to include both `<iosfwd>` and one or more of the other headers.\footnote{It is the implementation's responsibility to implement headers so that including `<iosfwd>` and other headers does not violate the rules about multiple occurrences of default arguments.}
29.3.2 Overview

The class template specialization basic_ios<charT, traits> serves as a virtual base class for the class templates basic_istream, basic_ostream, and class templates derived from them. basic_ios is a class template derived from both basic_istream<charT, traits> and basic_ostream<charT, traits>.

The class template specialization basic_streambuf<charT, traits> serves as a base class for class templates basic_stringbuf, basic_filebuf, and basic_syncbuf.

The class template specialization basic_istream<charT, traits> serves as a base class for class templates basic_istringstream and basic_ifstream.

The class template specialization basic_ostream<charT, traits> serves as a base class for class templates basic_ostringstream, basic_ofstream, and basic_osyncstream.

The class template specialization basic_iostream<charT, traits> serves as a base class for class templates basic_stringstream and basic_fstream.

[Note: For each of the class templates above, the program is ill-formed if traits::char_type is not the same type as charT (21.2). — end note]

Other typedef-names define instances of class templates specialized for char or wchar_t types.

Specializations of the class template fpos are used for specifying file position information. [Example: The types streampos and wstreampos are used for positioning streams specialized on char and wchar_t respectively. — end example]

[Note: This synopsis suggests a circularity between streampos and char_traits<char>. An implementation can avoid this circularity by substituting equivalent types. — end note]

29.4 Standard iostream objects

29.4.1 Header <iostream> synopsis

```cpp
#include <ios>  // see 29.5.1
#include <streambuf>  // see 29.6.1
#include <istream>  // see 29.7.1
#include <ostream>  // see 29.7.2

namespace std {
    extern istream cin;
    extern ostream cout;
    extern ostream cerr;
    extern ostream clog;

    extern wistream wcin;
    extern wostream wcout;
    extern wostream wcerr;
    extern wostream wclog;
}
```

29.4.2 Overview

In this Clause, the type name FILE refers to the type FILE declared in <cstdio> (29.12.1).

The header <iostream> declares objects that associate objects with the standard C streams provided for by the functions declared in <cstdio>, and includes all the headers necessary to use these objects.

The objects are constructed and the associations are established at some time prior to or during the first time an object of class ios_base::Init is constructed, and in any case before the body of main (6.9.3.1) begins execution. The objects are not destroyed during program execution.

Mixing operations on corresponding wide- and narrow-character streams follows the same semantics as mixing such operations on FILEs, as specified in the C standard library.

Concurrent access to a synchronized (29.5.3.4) standard iostream object’s formatted and unformatted input (29.7.4.1) and output (29.7.5.1) functions or a standard C stream by multiple threads does not result in a data race (6.9.2). [Note: If it is possible for them to do so, implementations should initialize the objects earlier than required. — end note]

284) If it is possible for them to do so, implementations should initialize the objects earlier than required.

285) Constructors and destructors for objects with static storage duration can access these objects to read input from stdin or write output to stdout or stderr.
Users must still synchronize concurrent use of these objects and streams by multiple threads if they wish to avoid interleaved characters. — end note

See also: ISO C 7.21.2

29.4.3 Narrow stream objects

```cpp
istream cin;
```

1. The object `cin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (29.12.1).

```cpp
After the object `cin` is initialized, `cin.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (29.5.5.2).
```

```cpp
ostream cout;
```

2. The object `cout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (29.12.1).

```cpp
ostream cerr;
```

3. The object `cerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

```cpp
After the object `cerr` is initialized, `cerr.flags() & unitbuf` is nonzero and `cerr.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (29.5.5.2).
```

```cpp
ostream clog;
```

4. The object `clog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

29.4.4 Wide stream objects

```cpp
wistream wcin;
```

1. The object `wcin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (29.12.1).

```cpp
After the object `wcin` is initialized, `wcin.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (29.5.5.2).
```

```cpp
wostream wcout;
```

2. The object `wcout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (29.12.1).

```cpp
wostream wcerr;
```

3. The object `wcerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

```cpp
After the object `wcerr` is initialized, `wcerr.flags() & unitbuf` is nonzero and `wcerr.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (29.5.5.2).
```

```cpp
wostream wclog;
```

4. The object `wclog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

29.5 Iostreams base classes

29.5.1 Header `<ios>` synopsis

```cpp
#include <iosfwd>     // see 29.3.1
```

namespace std {
  using streamoff = implementation-defined;
  using streamsize = implementation-defined;
  template<class stateT> class fpos;
}
class ios_base;
template<class charT, class traits = char_traits<charT>>
class basic_ios;

// 29.5.6, manipulators
ios_base& boolalpha (ios_base& str);
ios_base& noboolalpha (ios_base& str);
ios_base& showbase (ios_base& str);
ios_base& noshowbase (ios_base& str);
ios_base& showpoint (ios_base& str);
ios_base& noshowpoint (ios_base& str);
ios_base& showpos (ios_base& str);
ios_base& noshowpos (ios_base& str);
ios_base& skipws (ios_base& str);
ios_base& noskipws (ios_base& str);
ios_base& uppercase (ios_base& str);
ios_base& nouppercase (ios_base& str);
ios_base& unitbuf (ios_base& str);
ios_base& nounitbuf (ios_base& str);

// 29.5.6.2, adjust/field
ios_base& internal (ios_base& str);
ios_base& left (ios_base& str);
ios_base& right (ios_base& str);

// 29.5.6.3, base/field
ios_base& dec (ios_base& str);
ios_base& hex (ios_base& str);
ios_base& oct (ios_base& str);

// 29.5.6.4, float/field
ios_base& fixed (ios_base& str);
ios_base& scientific (ios_base& str);
ios_base& hexfloat (ios_base& str);
ios_base& defaultfloat (ios_base& str);

// 29.5.7, error reporting
enum class io_errc {
    stream = 1
};

template<> struct is_error_code_enum<io_errc> : public true_type { 
};

error_code make_error_code(io_errc e) noexcept;
error_condition make_error_condition(io_errc e) noexcept;
const error_category& iostream_category() noexcept;

} // namespace std

29.5.2 Types 

[stream.types]
using streamoff = implementation-defined;

1 The type streamoff is a synonym for one of the signed basic integral types of sufficient size to represent the maximum possible file size for the operating system.286

286) Typically long long.
The type `streamsize` is a synonym for one of the signed basic integral types. It is used to represent the number of characters transferred in an I/O operation, or the size of I/O buffers.\footnote{streamsize is used in most places where ISO C would use size_t.}

### 29.5.3 Class `ios_base`

```cpp
namespace std {
    class ios_base {
        public:
            class failure; // see below

            // 29.5.3.1.2, fmtflags
            using fmtflags = T1;
            static constexpr fmtflags boolalpha = unspecified;
            static constexpr fmtflags dec = unspecified;
            static constexpr fmtflags fixed = unspecified;
            static constexpr fmtflags hex = unspecified;
            static constexpr fmtflags internal = unspecified;
            static constexpr fmtflags left = unspecified;
            static constexpr fmtflags oct = unspecified;
            static constexpr fmtflags right = unspecified;
            static constexpr fmtflags scientific = unspecified;
            static constexpr fmtflags showbase = unspecified;
            static constexpr fmtflags showpoint = unspecified;
            static constexpr fmtflags showpos = unspecified;
            static constexpr fmtflags skipws = unspecified;
            static constexpr fmtflags unitbuf = unspecified;
            static constexpr fmtflags uppercase = unspecified;
            static constexpr fmtflags adjustfield = see below;
            static constexpr fmtflags basefield = see below;
            static constexpr fmtflags floatfield = see below;

            // 29.5.3.1.3, iostate
            using iostate = T2;
            static constexpr iostate badbit = unspecified;
            static constexpr iostate eofbit = unspecified;
            static constexpr iostate failbit = unspecified;
            static constexpr iostate goodbit = see below;

            // 29.5.3.1.4, openmode
            using openmode = T3;
            static constexpr openmode app = unspecified;
            static constexpr openmode ate = unspecified;
            static constexpr openmode binary = unspecified;
            static constexpr openmode in = unspecified;
            static constexpr openmode out = unspecified;
            static constexpr openmode trunc = unspecified;

            // 29.5.3.1.5, seekdir
            using seekdir = T4;
            static constexpr seekdir beg = unspecified;
            static constexpr seekdir cur = unspecified;
            static constexpr seekdir end = unspecified;

            class Init;

            // 29.5.3.2, fmtflags state
            fmtflags flags() const;
            fmtflags flags(fmtflags fmtfl);
            fmtflags setf(fmtflags fmtfl);
            fmtflags setf(fmtflags fmtfl, fmtflags mask);
            void unsetf(fmtflags mask);
```
streamsize precision() const;
streamsize precision(streamsize prec);
streamsize width() const;
streamsize width(streamsize wide);

// 29.5.3.3, locales
locale imbue(const locale& loc);
locale getloc() const;

// 29.5.3.5, storage
static int xalloc();
long& iword(int idx);
void*& pword(int idx);

// destructor
virtual ~ios_base();

// 29.5.3.6, callbacks
event { erase_event, imbue_event, copyfmt_event };
using event_callback = void (*)(event, ios_base&, int idx);
void register_callback(event_callback fn, int idx);

ios_base(const ios_base&) = delete;
ios_base& operator=(const ios_base&) = delete;
static bool sync_with_stdio(bool sync = true);

protected:
ios_base();

private:
static int index; // exposition only
long* iarray; // exposition only
void** parray; // exposition only
};

ios_base defines several member types:
1
1.1 — a type failure, defined as either a class derived from system_error or a synonym for a class derived from system_error;
1.2 — a class Init;
1.3 — three bitmask types, fmtflags, iostate, and openmode;
1.4 — an enumerated type, seekdir.

2 It maintains several kinds of data:
2.1 — state information that reflects the integrity of the stream buffer;
2.2 — control information that influences how to interpret (format) input sequences and how to generate (format) output sequences;
2.3 — additional information that is stored by the program for its private use.

3 [Note: For the sake of exposition, the maintained data is presented here as:
3.1 — static int index, specifies the next available unique index for the integer or pointer arrays maintained for the private use of the program, initialized to an unspecifed value;
3.2 — long* iarray, points to the first element of an arbitrary-length long array maintained for the private use of the program;
3.3 — void** parray, points to the first element of an arbitrary-length pointer array maintained for the private use of the program.
— end note]
29.5.3.1 Types

29.5.3.1.1 Class ios_base::failure

namespace std {
  class ios_base::failure : public system_error {
    public:
      explicit failure(const string& msg, const error_code& ec = io_errc::stream);
      explicit failure(const char* msg, const error_code& ec = io_errc::stream);
  };
}

1. An implementation is permitted to define ios_base::failure as a synonym for a class with equivalent functionality to class ios_base::failure shown in this subclause. [Note: When ios_base::failure is a synonym for another type, that type is required to provide a nested type failure to emulate the injected-class-name. — end note] The class failure defines the base class for the types of all objects thrown as exceptions, by functions in the iostreams library, to report errors detected during stream buffer operations.

2. When throwing ios_base::failure exceptions, implementations should provide values of ec that identify the specific reason for the failure. [Note: Errors arising from the operating system would typically be reported as system_category() errors with an error value of the error number reported by the operating system. Errors arising from within the stream library would typically be reported as error_code(io_errc::stream, iostream_category()). — end note]

   explicit failure(const string& msg, const error_code& ec = io_errc::stream);
3. Effects: Constructs the base class with msg and ec.

   explicit failure(const char* msg, const error_code& ec = io_errc::stream);
4. Effects: Constructs the base class with msg and ec.

29.5.3.1.2 Type ios_base::fmtflags

using fmtflags = T1;

1. The type fmtflags is a bitmask type (16.4.2.2.4). Setting its elements has the effects indicated in Table 116.

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolalpha</td>
<td>insert and extract bool type in alphabetic format</td>
</tr>
<tr>
<td>dec</td>
<td>converts integer input or generates integer output in decimal base</td>
</tr>
<tr>
<td>fixed</td>
<td>generate floating-point output in fixed-point notation</td>
</tr>
<tr>
<td>hex</td>
<td>converts integer input or generates integer output in hexadecimal base</td>
</tr>
<tr>
<td>internal</td>
<td>adds fill characters at a designated internal point in certain generated output, or identical to right if no such point is designated</td>
</tr>
<tr>
<td>left</td>
<td>adds fill characters on the right (final positions) of certain generated output</td>
</tr>
<tr>
<td>oct</td>
<td>converts integer input or generates integer output in octal base</td>
</tr>
<tr>
<td>right</td>
<td>adds fill characters on the left (initial positions) of certain generated output</td>
</tr>
<tr>
<td>scientific</td>
<td>generates floating-point output in scientific notation</td>
</tr>
<tr>
<td>showbase</td>
<td>generates a prefix indicating the numeric base of generated integer output</td>
</tr>
<tr>
<td>showpoint</td>
<td>generates a decimal-point character unconditionally in generated floating-point output</td>
</tr>
<tr>
<td>showpos</td>
<td>generates a + sign in non-negative generated numeric output</td>
</tr>
<tr>
<td>skips</td>
<td>skips leading whitespace before certain input operations</td>
</tr>
<tr>
<td>unitbuf</td>
<td>flushes output after each output operation</td>
</tr>
<tr>
<td>uppercase</td>
<td>replaces certain lowercase letters with their uppercase equivalents in generated output</td>
</tr>
</tbody>
</table>

2. Type fmtflags also defines the constants indicated in Table 117.
Table 117: fmtflags constants

<table>
<thead>
<tr>
<th>Constant</th>
<th>Allowable values</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield</td>
<td>left</td>
</tr>
<tr>
<td>basefield</td>
<td>dec</td>
</tr>
<tr>
<td>floatfield</td>
<td>scientific</td>
</tr>
</tbody>
</table>

29.5.3.1.3 Type ios_base::iostate

using iostate = T2;

The type iostate is a bitmask type (16.4.2.2.4) that contains the elements indicated in Table 118.

Table 118: iostate effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>badbit</td>
<td>indicates a loss of integrity in an input or output sequence (such as an irrecoverable read error from a file);</td>
</tr>
<tr>
<td>eofbit</td>
<td>indicates that an input operation reached the end of an input sequence;</td>
</tr>
<tr>
<td>failbit</td>
<td>indicates that an input operation failed to read the expected characters, or that an output operation failed to generate the desired characters.</td>
</tr>
</tbody>
</table>

Type iostate also defines the constant:

— goodbit, the value zero.

29.5.3.1.4 Type ios_base::openmode

using openmode = T3;

The type openmode is a bitmask type (16.4.2.2.4). It contains the elements indicated in Table 119.

Table 119: openmode effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>app</td>
<td>seek to end before each write</td>
</tr>
<tr>
<td>ate</td>
<td>open and seek to end immediately after opening</td>
</tr>
<tr>
<td>binary</td>
<td>perform input and output in binary mode (as opposed to text mode)</td>
</tr>
<tr>
<td>in</td>
<td>open for input</td>
</tr>
<tr>
<td>out</td>
<td>open for output</td>
</tr>
<tr>
<td>trunc</td>
<td>truncate an existing stream when opening</td>
</tr>
</tbody>
</table>

29.5.3.1.5 Type ios_base::seekdir

using seekdir = T4;

The type seekdir is an enumerated type (16.4.2.2.3) that contains the elements indicated in Table 120.

Table 120: seekdir effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>beg</td>
<td>request a seek (for subsequent input or output) relative to the beginning of the stream</td>
</tr>
<tr>
<td>cur</td>
<td>request a seek relative to the current position within the sequence</td>
</tr>
<tr>
<td>end</td>
<td>request a seek relative to the current end of the sequence</td>
</tr>
</tbody>
</table>
29.5.3.1.6 Class ios_base::Init

```cpp
namespace std {
    class ios_base::Init {
        public:
            Init();
            Init(const Init&) = default;
            ~Init();
            Init& operator=(const Init&) = default;
        private:
            static int init_cnt;  // exposition only
        }
    }
}
```

1 The class Init describes an object whose construction ensures the construction of the eight objects declared in `<iostream>` (29.4) that associate file stream buffers with the standard C streams provided for by the functions declared in `<cstdio>` (29.12.1).

2 For the sake of exposition, the maintained data is presented here as:

   — static int init_cnt, counts the number of constructor and destructor calls for class Init, initialized to zero.

   Init();

3 Effects: Constructs and initializes the objects cin, cout, cerr, clog, wcin, wcout, wcerr, and wclog if they have not already been constructed and initialized.

   ~Init();

4 Effects: If there are no other instances of the class still in existence, calls cout.flush(), cerr.flush(), clog.flush(), wcout.flush(), wcerr.flush(), and wclog.flush().

29.5.3.2 State functions

```cpp
fmtflags flags() const;
```

1 Returns: The format control information for both input and output.

```cpp
fmtflags flags(fmtflags fmtfl);
```

2 Postconditions: fmtfl == flags().

3 Returns: The previous value of flags().

```cpp
fmtflags setf(fmtflags fmtfl);
```

4 Effects: Sets fmtfl in flags().

5 Returns: The previous value of flags().

```cpp
fmtflags setf(fmtflags fmtfl, fmtflags mask);
```

6 Effects: Clears mask in flags(), sets fmtfl & mask in flags().

7 Returns: The previous value of flags().

```cpp
void unsetf(fmtflags mask);
```

8 Effects: Clears mask in flags().

```cpp
streamsize precision() const;
```

9 Returns: The precision to generate on certain output conversions.

```cpp
streamsize precision(streamsize prec);
```

10 Postconditions: prec == precision().

11 Returns: The previous value of precision().

```cpp
streamsize width() const;
```

12 Returns: The minimum field width (number of characters) to generate on certain output conversions.
streamsize width(streamsize wide);

Postconditions: wide == width().

Returns: The previous value of width().

29.5.3.3 Functions

locale imbue(const locale& loc);

Effects: Calls each registered callback pair (fn, idx)\(^{(29.5.3.6)}\) as (*fn)(imbue_event, *this, idx) at such a time that a call to ios_base::getloc() from within fn returns the new locale value loc.

Postconditions: loc == getloc().

Returns: The previous value of getloc().

locale getloc() const;

Returns: If no locale has been imbued, a copy of the global C++ locale, locale(), in effect at the time of construction. Otherwise, returns the imbued locale, to be used to perform locale-dependent input and output operations.

29.5.3.4 Static members

static bool sync_with_stdio(bool sync = true);

Effects: If any input or output operation has occurred using the standard streams prior to the call, the effect is implementation-defined. Otherwise, called with a false argument, it allows the standard streams to operate independently of the standard C streams.

Returns: true if the previous state of the standard iostream objects\(^{(29.4)}\) was synchronized and otherwise returns false. The first time it is called, the function returns true.

Remarks: When a standard iostream object str is synchronized with a standard stdio stream f, the effect of inserting a character c by

\[
\text{fputc}(f, c);
\]

is the same as the effect of

\[
\text{str.rdbuf()]->sputc(c)};
\]

for any sequences of characters; the effect of extracting a character c by

\[
c = \text{fgetc}(f);
\]

is the same as the effect of

\[
c = \text{str.rdbuf()]->sbumpc}();
\]

for any sequences of characters; and the effect of pushing back a character c by

\[
\text{ungetc}(c, f);
\]

is the same as the effect of

\[
\text{str.rdbuf()]->sputbackc}(c);
\]

for any sequence of characters.\(^{288}\)

29.5.3.5 Storage functions

static int xalloc();

Returns: index ++.

Remarks: Concurrent access to this function by multiple threads does not result in a data race (6.9.2).

long& iword(int idx);

Preconditions: idx is a value obtained by a call to xalloc.

Effects: If iarray is a null pointer, allocates an array of long of unspecified size and stores a pointer to its first element in iarray. The function then extends the array pointed at by iarray as necessary to include the element iarray[idx]. Each newly allocated element of the array is initialized to zero. The reference returned

\(^{288}\)This implies that operations on a standard iostream object can be mixed arbitrarily with operations on the corresponding stdio stream. In practical terms, synchronization usually means that a standard iostream object and a standard stdio object share a buffer.
is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to `copyfmt`, calling `pword` with the same index yields another reference to the same value. If the function fails and `*this` is a base class subobject of a `basic_ios<>` object or subobject, the effect is equivalent to calling `basic_ios<>::setstate(badbit)` on the derived object (which may throw failure).

Returns: On success `iarray[idx]`. On failure, a valid `long&` initialized to 0.

```cpp
void*& pword(int idx);
```

Preconditions: `idx` is a value obtained by a call to `xalloc`.

Effects: If `parray` is a null pointer, allocates an array of pointers to `void` of unspecified size and stores a pointer to its first element in `parray`. The function then extends the array pointed at by `parray` as necessary to include the element `parray[idx]`. Each newly allocated element of the array is initialized to a null pointer. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to `copyfmt`, calling `pword` with the same index yields another reference to the same value. If the function fails and `*this` is a base class subobject of a `basic_ios<>` object or subobject, the effect is equivalent to calling `basic_ios<>::setstate(badbit)` on the derived object (which may throw failure).

Returns: On success `parray[idx]`. On failure a valid `void*` initialized to 0.

Remarks: After a subsequent call to `pword(int)` for the same object, the earlier return value may no longer be valid.

### 29.5.3.6 Callbacks

```cpp
void register_callback(event_callback fn, int idx);
```

Preconditions: The function `fn` does not throw exceptions.

Effects: Registers the pair `(fn, idx)` such that during calls to `imbue()` (29.5.3.3), `copyfmt()`, or `~ios_base()` (29.5.3.7), the function `fn` is called with argument `idx`. Functions registered are called when an event occurs, in opposite order of registration. Functions registered while a callback function is active are not called until the next event.

Remarks: Identical pairs are not merged. A function registered twice will be called twice.

### 29.5.3.7 Constructors and destructor

```cpp
ios_base();
```

Effects: Each `ios_base` member has an indeterminate value after construction. The object’s members shall be initialized by calling `basic_ios::init` before the object’s first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

```cpp
~ios_base();
```

Effects: Calls each registered callback pair `(fn, idx)` (29.5.3.6) as `(fn)(erase_event, *this, idx)` at such time that any `ios_base` member function called from within `fn` has well-defined results.

### 29.5.4 Class template `fpos`

```cpp
namespace std {
    template<class stateT> class fpos {
    public:
        // 29.5.4.1, members
        stateT state() const;
        void state(stateT);
    private:
        stateT st; // exposition only
    };
}
```

289] An implementation is free to implement both the integer array pointed at by `iarray` and the pointer array pointed at by `parray` as sparse data structures, possibly with a one-element cache for each.

290] For example, because it cannot allocate space.

291] For example, because it cannot allocate space.
29.5.4.1 Members

void state(stateT s);

Effects: Assigns s to st.

stateT state() const;

Returns: Current value of st.

29.5.4.2 Requirements

An fpos type specifies file position information. It holds a state object whose type is equal to the template parameter stateT. Type stateT shall meet the Cpp17DefaultConstructible (Table 27), Cpp17CopyConstructible (Table 29), Cpp17CopyAssignable (Table 31), and Cpp17Destructible (Table 32) requirements. If is_trivially_copy_constructible_v<stateT> is true, then fpos<stateT> has a trivial copy constructor. If is_trivially_copy_assignable_v<stateT> is true, then fpos<stateT> has a trivial copy assignment operator. If is_trivially_destructible_v<stateT> is true, then fpos<stateT> has a trivial destructor. All specializations of fpos meet the Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, Cpp17Destructible, and Cpp17EqualityComparable (Table 25) requirements. In addition, the expressions shown in Table 121 are valid and have the indicated semantics.

In that table,

(1.1) — P refers to an instance of fpos,
(1.2) — p and q refer to values of type P or const P,
(1.3) — pl and ql refer to modifiable lvalues of type P,
(1.4) — 0 refers to type streamoff, and
(1.5) — o refers to a value of type streamoff or const streamoff.

Table 121: Position type requirements

2 Stream operations that return a value of type traits::pos_type return P(O(-1)) as an invalid value to signal an error. If this value is used as an argument to any istream, ostream, or streambuf member that accepts a value of type traits::pos_type then the behavior of that function is undefined.

29.5.5 Class template basic_ios

29.5.5.1 Overview
class basic_ios : public ios_base {
public:
    using char_type = charT;
    using int_type = typename traits::int_type;
    using pos_type = typename traits::pos_type;
    using off_type = typename traits::off_type;
    using traits_type = traits;

    // 29.5.5.4 flags functions
    explicit operator bool() const;
    bool operator!() const;
    iostate rdstate() const;
    void clear(iostate state = goodbit);
    void setstate(iostate state);
    bool good() const;
    bool eof() const;
    bool fail() const;
    bool bad() const;

    iostate exceptions() const;
    void exceptions(iostate except);

    // 29.5.5.2 constructor/destructor
    explicit basic_ios(basic_streambuf<charT, traits>* sb);
    virtual ~basic_ios();

    // 29.5.5.3 members
    basic_ostream<charT, traits>* tie() const;
    basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);
    basic_streambuf<charT, traits>* rdbuf() const;
    basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);
    basic_ios& copyfmt(const basic_ios& rhs);
    char_type fill() const;
    char_type fill(char_type ch);
    locale imbue(const locale& loc);
    char narrow(char_type c, char dfault) const;
    char_type widen(char c) const;
    basic_ios(const basic_ios&) = delete;
    basic_ios& operator=(const basic_ios&) = delete;

protected:
    basic_ios();
    void init(basic_streambuf<charT, traits>* sb);
    void move(basic_ios& rhs);
    void move(basic_ios&& rhs);
    void swap(basic_ios& rhs) noexcept;
    void set_rdbuf(basic_streambuf<charT, traits>* sb);
};

29.5.5.2 Constructors

explicit basic_ios(basic_streambuf<charT, traits>* sb);

Effects: Assigns initial values to its member objects by calling init(sb).
basic_ios();

Effects: Leaves its member objects uninitialzed. The object shall be initialized by calling basic_ios::init before its first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

basic_ios();

Remarks: The destructor does not destroy rdbuf().

void init(basic_streambuf<charT, traits>* sb);

Postconditions: The postconditions of this function are indicated in Table 122.

Table 122: basic_ios::init() effects  [tab:basic.ios.cons]

29.5.5.3 Member functions  [basic.ios.members]

basic_ostream<charT, traits>* tie() const;

Returns: An output sequence that is tied to (synchronized with) the sequence controlled by the stream buffer.

basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);

Preconditions: If tiestr is not null, tiestr is not reachable by traversing the linked list of tied stream objects starting from tiestr->tie().

Postconditions: tiestr == tie().

Returns: The previous value of tie().

basic_streambuf<charT, traits>* rdbuf() const;

Returns: A pointer to the streambuf associated with the stream.

basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);

Effects: Calls clear().

Postconditions: sb == rdbuf().

Returns: The previous value of rdbuf().

locale imbue(const locale& loc);

Effects: Calls ios_base::imbue(loc) (29.5.3.3) and if rdbuf() != 0 then rdbuf()->pubimbue(loc) (29.6.3.2.1).

Returns: The prior value of ios_base::imbue().

char narrow(char_type c, char dfault) const;

Returns: use_facet<ctype<char_type>>((getloc()).narrow(c, dfault)

char_type widen(char c) const;

Returns: use_facet<ctype<char_type>>((getloc()).widen(c)

char_type fill() const;

Returns: The character used to pad (fill) an output conversion to the specified field width.
char_type fill(char_type fillch);

   Postconditions: traits::eq(fillch, fill()).

   Returns: The previous value of fill().

basic_ios& copyfmt(const basic_ios& rhs);

   Effects: If (this == addressof(rhs)) is true does nothing. Otherwise assigns to the member objects of this the corresponding member objects of rhs as follows:

   (16.1) — calls each registered callback pair (fn, idx) as (*fn)(erase_event, *this, idx);
   (16.2) — then, assigns to the member objects of *this the corresponding member objects of rhs, except that
   (16.2.1) — rdstate(), rdbuf(), and exceptions() are left unchanged;
   (16.2.2) — if any newly stored pointer values in *this point at objects stored outside the object rhs and those objects are destroyed when rhs is destroyed, the newly stored pointer values are altered to point at newly constructed copies of the objects;
   (16.3) — then, calls each callback pair that was copied from rhs as (*fn)(copyfmt_event, *this, idx);
   (16.4) — then, calls exceptions(rhs.exceptions()).

   [Note: The second pass through the callback pairs permits a copied pword value to be zeroed, or to have its referent deep copied or reference counted, or to have other special action taken. — end note]

   Postconditions: The postconditions of this function are indicated in Table 123.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdbuf()</td>
<td>unchanged</td>
</tr>
<tr>
<td>tie()</td>
<td>rhs.tie()</td>
</tr>
<tr>
<td>rdstate()</td>
<td>unchanged</td>
</tr>
<tr>
<td>exceptions()</td>
<td>rhs.exceptions()</td>
</tr>
<tr>
<td>flags()</td>
<td>rhs.flags()</td>
</tr>
<tr>
<td>width()</td>
<td>rhs.width()</td>
</tr>
<tr>
<td>precision()</td>
<td>rhs.precision()</td>
</tr>
<tr>
<td>fill()</td>
<td>rhs.fill()</td>
</tr>
<tr>
<td>getloc()</td>
<td>rhs.getloc()</td>
</tr>
</tbody>
</table>

   Returns: *this.

void move(basic_ios& rhs);
void move(basic_ios&& rhs);

   Postconditions: *this has the state that rhs had before the function call, except that rdbuf() returns nullptr. rhs is in a valid but unspecified state, except that rhs.rdbuf() returns the same value as it returned before the function call, and rhs.tie() returns nullptr.

void swap(basic_ios& rhs) noexcept;

   Effects: The states of *this and rhs are exchanged, except that rdbuf() returns the same value as it returned before the function call, and rhs.rdbuf() returns the same value as it returned before the function call.

void set_rdbuf(basic_streambuf<charT, traits>* sb);

   Preconditions: sb != nullptr is true.

   Effects: Associates the basic_streambuf object pointed to by sb with this stream without calling clear().

   Postconditions: rdbuf() == sb is true.

   Throws: Nothing.

292) This suggests an infinite amount of copying, but the implementation can keep track of the maximum element of the arrays that is nonzero.
29.5.5.4 Flags functions

```cpp
explicit operator bool() const;
    Returns: !fail().

bool operator!() const;
    Returns: fail().

iostate rdstate() const;
    Returns: The error state of the stream buffer.

void clear(iostate state = goodbit);
    Effects: If ((state | (rdbuf() ? goodbit : badbit)) & exceptions()) == 0, returns. Otherwise, the function throws an object of class ios_base::failure (29.5.3.1), constructed with implementation-defined argument values.
    Postconditions: If rdbuf() != 0 then state == rdstate(); otherwise rdstate() == (state | ios_base::badbit).

void setstate(iostate state);
    Effects: Calls clear(rdstate() | state) (which may throw ios_base::failure (29.5.3.1)).

bool good() const;
    Returns: rdstate() == 0

bool eof() const;
    Returns: true if eofbit is set in rdstate().

bool fail() const;
    Returns: true if failbit or badbit is set in rdstate().

bool bad() const;
    Returns: true if badbit is set in rdstate().

iostate exceptions() const;
    Returns: A mask that determines what elements set in rdstate() cause exceptions to be thrown.

void exceptions(iostate except);
    Effects: Calls clear(rdstate()).
    Postconditions: except == exceptions().
```

29.5.6 ios_base manipulators

29.5.6.1 fmtflags manipulators

Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

```cpp
ios_base& boolalpha(ios_base& str);
    Effects: Calls str.setf(ios_base::boolalpha).
    Returns: str.

ios_base& noboolalpha(ios_base& str);
    Effects: Calls str.unsetf(ios_base::boolalpha).
    Returns: str.

ios_base& showbase(ios_base& str);
    Effects: Calls str.setf(ios_base::showbase).
    Returns: str.
```

293) Checking badbit also for fail() is historical practice.
ios_base& noshowbase(ios_base& str);
   Effects: Calls str.unsetf(ios_base::showbase).
   Returns: str.

ios_base& showpoint(ios_base& str);
   Effects: Calls str.setf(ios_base::showpoint).
   Returns: str.

ios_base& noshowpoint(ios_base& str);
   Effects: Calls str.unsetf(ios_base::showpoint).
   Returns: str.

ios_base& showpos(ios_base& str);
   Effects: Calls str.setf(ios_base::showpos).
   Returns: str.

ios_base& noshowpos(ios_base& str);
   Effects: Calls str.unsetf(ios_base::showpos).
   Returns: str.

ios_base& skipws(ios_base& str);
   Effects: Calls str.setf(ios_base::skipws).
   Returns: str.

ios_base& noskipws(ios_base& str);
   Effects: Calls str.unsetf(ios_base::skipws).
   Returns: str.

ios_base& uppercase(ios_base& str);
   Effects: Calls str.setf(ios_base::uppercase).
   Returns: str.

ios_base& nouppercase(ios_base& str);
   Effects: Calls str.unsetf(ios_base::uppercase).
   Returns: str.

ios_base& unitbuf(ios_base& str);
   Effects: Calls str.setf(ios_base::unitbuf).
   Returns: str.

ios_base& nounitbuf(ios_base& str);
   Effects: Calls str.unsetf(ios_base::unitbuf).
   Returns: str.

29.5.6.2 adjustfield manipulators
   Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

ios_base& internal(ios_base& str);
   Effects: Calls str.setf(ios_base::internal, ios_base::adjustfield).
   Returns: str.

ios_base& left(ios_base& str);
   Effects: Calls str.setf(ios_base::left, ios_base::adjustfield).
   Returns: str.
ios_base& right(ios_base& str);

Effects: Calls str.setf(ios_base::right, ios_base::adjustfield).
Returns: str.

29.5.6.3 basefield manipulators

Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

ios_base& dec(ios_base& str);

Effects: Calls str.setf(ios_base::dec, ios_base::basefield).
Returns: str.

ios_base& hex(ios_base& str);

Effects: Calls str.setf(ios_base::hex, ios_base::basefield).
Returns: str.

ios_base& oct(ios_base& str);

Effects: Calls str.setf(ios_base::oct, ios_base::basefield).
Returns: str.

29.5.6.4 floatfield manipulators

Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

ios_base& fixed(ios_base& str);

Effects: Calls str.setf(ios_base::fixed, ios_base::floatfield).
Returns: str.

ios_base& scientific(ios_base& str);

Effects: Calls str.setf(ios_base::scientific, ios_base::floatfield).
Returns: str.

ios_base& hexfloat(ios_base& str);

Effects: Calls str.setf(ios_base::fixed | ios_base::scientific, ios_base::floatfield).
Returns: str.

[Note: The more obvious use of ios_base::hex to specify hexadecimal floating-point format would change the meaning of existing well-defined programs. C++ 2003 gives no meaning to the combination of fixed and scientific. —end note]

ios_base& defaultfloat(ios_base& str);

Effects: Calls str.unsetf(ios_base::floatfield).
Returns: str.

29.5.7 Error reporting

error_code make_error_code(io_errc e) noexcept;

Returns: error_code(static_cast<int>(e), iostream_category()).

error_condition make_error_condition(io_errc e) noexcept;

Returns: error_condition(static_cast<int>(e), iostream_category()).

const error_category& iostream_category() noexcept;

Returns: A reference to an object of a type derived from class error_category.

The object’s default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object’s name virtual function shall return a pointer to the string “iostream”.

294) The function signature dec(ios_base&) can be called by the function signature basic_ostream& stream::operator<<(ios_base& ()), to permit expressions of the form cout << dec to change the formal flags stored in cout.
29.6 Stream buffers

29.6.1 Header \texttt{<streambuf> synopsis}

\begin{verbatim}
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_streambuf;
    using streambuf = basic_streambuf<char>;
    using wstreambuf = basic_streambuf<wchar_t>;
}
\end{verbatim}

The header \texttt{<streambuf>} defines types that control input from and output to character sequences.

29.6.2 Stream buffer requirements

Stream buffers can impose various constraints on the sequences they control. Some constraints are:

1. The controlled input sequence can be not readable.
2. The controlled output sequence can be not writable.
3. The controlled sequences can be associated with the contents of other representations for character sequences, such as external files.
4. The controlled sequences can support operations directly to or from associated sequences.
5. The controlled sequences can impose limitations on how the program can read characters from a sequence, write characters to a sequence, put characters back into an input sequence, or alter the stream position.

Each sequence is characterized by three pointers which, if non-null, all point into the same \texttt{charT} array object. The array object represents, at any moment, a (sub)sequence of characters from the sequence. Operations performed on a sequence alter the values stored in these pointers, perform reads and writes directly to or from associated sequences, and alter "the stream position" and conversion state as needed to maintain this subsequence relationship. The three pointers are:

1. the beginning pointer, or lowest element address in the array (called \texttt{xbeg} here);
2. the next pointer, or next element address that is a current candidate for reading or writing (called \texttt{xnext} here);
3. the end pointer, or first element address beyond the end of the array (called \texttt{xend} here).

The following semantic constraints shall always apply for any set of three pointers for a sequence, using the pointer names given immediately above:

1. If \texttt{xnext} is not a null pointer, then \texttt{xbeg} and \texttt{xend} shall also be non-null pointers into the same \texttt{charT} array, as described above; otherwise, \texttt{xbeg} and \texttt{xend} shall also be null.
2. If \texttt{xnext} is not a null pointer and \texttt{xnext} \texttt{<} \texttt{xend} for an output sequence, then a write position is available. In this case, \texttt{*xnext} shall be assignable as the next element to write (to put, or to store a character value, into the sequence).
3. If \texttt{xnext} is not a null pointer and \texttt{xbeg} \texttt{<} \texttt{xnext} for an input sequence, then a putback position is available. In this case, \texttt{xnext[-1]} shall have a defined value and is the next (preceding) element to store a character that is put back into the input sequence.
4. If \texttt{xnext} is not a null pointer and \texttt{xnext} \texttt{<} \texttt{xend} for an input sequence, then a read position is available. In this case, \texttt{*xnext} shall have a defined value and is the next element to read (to get, or to obtain a character value, from the sequence).

29.6.3 Class template basic_streambuf

\begin{verbatim}
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_streambuf {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        virtual ~basic_streambuf();
    }
\end{verbatim}

§ 29.6.3 1347
// 29.6.3.2.1, locales
locale pubimbue(const locale& loc);
locale getloc() const;

// 29.6.3.2.2, buffer and positioning
basic_streambuf* pubsetbuf(char_type* s, streamsize n);
pos_type pubseekoff(off_type off, ios_base::seekdir way,
                    ios_base::openmode which
                    = ios_base::in | ios_base::out);
pos_type pubseekpos(pos_type sp,
                    ios_base::openmode which
                    = ios_base::in | ios_base::out);
int pubsync();

// get and put areas
// 29.6.3.2.3, get area
streamsize in_avail();
int_type snextc();
int_type sbumpc();
int_type sgetc();
streamsize sgetn(char_type* s, streamsize n);

// 29.6.3.2.4, putback
int_type sputbackc(char_type c);
int_type sungetc();

// 29.6.3.2.5, put area
int_type sputc(char_type c);
streamsize sputn(const char_type* s, streamsize n);

protected:
basic_streambuf();
basic_streambuf(const basic_streambuf& rhs);
basic_streambuf& operator=(const basic_streambuf& rhs);
void swap(basic_streambuf& rhs);

// 29.6.3.3.2, get area access
char_type* eback() const;
char_type* gptr() const;
char_type* egptr() const;
void gbump(int n);
void setg(char_type* gbeg, char_type* gnext, char_type* gend);

// 29.6.3.3.3, put area access
char_type* pbase() const;
char_type* pptr() const;
char_type* epptr() const;
void pbump(int n);
void setp(char_type* pbeg, char_type* pend);

// 29.6.3.4, virtual functions
// 29.6.3.4.1, locales
virtual void imbue(const locale& loc);

// 29.6.3.4.2, buffer management and positioning
virtual basic_streambuf* setbuf(char_type* s, streamsize n);
virtual pos_type seekoff(off_type off, ios_base::seekdir way,
                         ios_base::openmode which
                         = ios_base::in | ios_base::out);
virtual pos_type seekpos(pos_type sp,
                         ios_base::openmode which
                         = ios_base::in | ios_base::out);
virtual int sync();
The class template basic_streambuf serves as an abstract base class for deriving various stream buffers whose objects each control two character sequences:

- a character input sequence;
- a character output sequence.

### 29.6.3.1 Constructors

basic_streambuf();

*Effects:* Initializes:

- all pointer member objects to null pointers,
- the getloc() member to a copy the global locale, locale(), at the time of construction.

*Remarks:* Once the getloc() member is initialized, results of calling locale member functions, and of members of facets so obtained, can safely be cached until the next time the member imbue is called.

basic_streambuf(const basic_streambuf& rhs);

*Postconditions:*

- eback() == rhs.eback()
- gptr() == rhs.gptr()
- egptr() == rhs.egptr()
- pbase() == rhs.pbase()
- pptr() == rhs.pptr()
- epptr() == rhs.epptr()
- getloc() == rhs.getloc()

~basic_streambuf();

*Effects:* None.

### 29.6.3.2 Public member functions

#### 29.6.3.2.1 Locales

locale pubimbue(const locale& loc);

*Effects:* Calls imbue(loc).

*Postconditions:* loc == getloc().

*Returns:* Previous value of getloc().

locale getloc() const;

*Returns:* If pubimbue() has ever been called, then the last value of loc supplied, otherwise the current global locale, locale(), in effect at the time of construction. If called after pubimbue() has been called but before pubimbue has returned (i.e., from within the call of imbue()) then it returns the previous value.

---

295) The default constructor is protected for class basic_streambuf to assure that only objects for classes derived from this class may be constructed.
29.6.3.2.2 Buffer management and positioning

basic_streambuf* pubsetbuf(char_type* s, streamsize n);

1 Returns: setbuf(s, n).

pos_type pubseekoff(off_type off, ios_base::seekdir way,
ios_base::openmode which
    = ios_base::in | ios_base::out);

2 Returns: seekoff(off, way, which).

pos_type pubseekpos(pos_type sp,
ios_base::openmode which
    = ios_base::in | ios_base::out);

3 Returns: seekpos(sp, which).

int pubsync();

4 Returns: sync().

29.6.3.2.3 Get area

streamsize in_avail();

1 Returns: If a read position is available, returns egptr() - gptr(). Otherwise returns showmanyc() (29.6.3.4.3).

int_type snextc();

2 Effects: Calls sbumpc().

3 Returns: If that function returns traits::eof(), returns traits::eof(). Otherwise, returns sgetc().

int_type sbumpc();

4 Effects: If the input sequence read position is not available, returns uflow(). Otherwise, returns traits::to_int_type(*gptr()) and increments the next pointer for the input sequence.

int_type sgetc();

5 Returns: If the input sequence read position is not available, returns underflow(). Otherwise, returns traits::to_int_type(*gptr()).

streamsize sgetn(const char_type* s, streamsize n);

6 Returns: xsgetn(s, n).

29.6.3.2.4 Putback

int_type sputbackc(char_type c);

1 Effects: If the input sequence putback position is not available, or if traits::eq(c, gptr()[-1]) is false, returns pbackfail(trait::to_int_type(c)). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

int_type sungetc();

2 Effects: If the input sequence putback position is not available, returns pbackfail(). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

29.6.3.2.5 Put area

int_type sputc(char_type c);

1 Effects: If the output sequence write position is not available, returns overflow(traits::to_int_type(c)). Otherwise, stores c at the next pointer for the output sequence, increments the pointer, and returns traits::to_int_type(c).

streamsize sputn(const char_type* s, streamsize n);

2 Returns: xsputn(s, n).
29.6.3.3 Protected member functions

29.6.3.3.1 Assignment

basic_streambuf& operator=(const basic_streambuf& rhs);

Postconditions:

1. 
   - `eback()` == `rhs.eback()`
2. 
   - `gptr()` == `rhs.gptr()`
3. 
   - `egptr()` == `rhs.egptr()`
4. 
   - `pbase()` == `rhs.pbase()`
5. 
   - `pptr()` == `rhs.pptr()`
6. 
   - `epptr()` == `rhs.epptr()`
7. 
   - `getloc()` == `rhs.getloc()`

Returns: *this.

void swap(basic_streambuf& rhs);

Effects: Swaps the data members of `rhs` and *this.

29.6.3.3.2 Get area access

char_type* eback() const;

Returns: The beginning pointer for the input sequence.

char_type* gptr() const;

Returns: The next pointer for the input sequence.

char_type* egptr() const;

Returns: The end pointer for the input sequence.

void gbump(int n);

Effects: Adds `n` to the next pointer for the input sequence.

void setg(char_type* gbeg, char_type* gnext, char_type* gend);

Postconditions: `gbeg` == `eback()`, `gnext` == `gptr()`, and `gend` == `egptr()` are all true.

29.6.3.3.3 Put area access

char_type* pbase() const;

Returns: The beginning pointer for the output sequence.

char_type* pptr() const;

Returns: The next pointer for the output sequence.

char_type* epptr() const;

Returns: The end pointer for the output sequence.

void pbump(int n);

Effects: Adds `n` to the next pointer for the output sequence.

void setp(char_type* pbeg, char_type* pend);

Postconditions: `pbeg` == `pbase()`, `pbeg` == `pptr()`, and `pend` == `epptr()` are all true.

29.6.3.4 Virtual functions

29.6.3.4.1 Locales

void imbue(const locale&);

Effects: Change any translations based on locale.
Remarks: Allows the derived class to be informed of changes in locale at the time they occur. Between invocations of this function a class derived from streambuf can safely cache results of calls to locale functions and to members of facets so obtained.

Default behavior: Does nothing.

29.6.3.4.2 Buffer management and positioning

```cpp
basic_streambuf* setbuf(char_type* s, streamsize n);
```

Effects: Influences stream buffering in a way that is defined separately for each class derived from basic_streambuf in this Clause (29.8.2.4, 29.9.2.4).

Default behavior: Does nothing. Returns this.

```cpp
pos_type seekoff(off_type off, ios_base::seekdir way, ios_base::openmode which = ios_base::in | ios_base::out);
```

Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from basic_streambuf in this Clause (29.8.2.4, 29.9.2.4).

Default behavior: Returns pos_type(off_type(-1)).

```cpp
pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out);
```

Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from basic_streambuf in this Clause (29.8.2, 29.9.2).

Default behavior: Returns pos_type(off_type(-1)).

```cpp
int sync();
```

Effects: Synchronizes the controlled sequences with the arrays. That is, if pbase() is non-null the characters between pbase() and pptr() are written to the controlled sequence. The pointers may then be reset as appropriate.

Returns: -1 on failure. What constitutes failure is determined by each derived class (29.9.2.4).

Default behavior: Returns zero.

29.6.3.4.3 Get area

```cpp
streamsize showmanyc();
```

Returns: An estimate of the number of characters available in the sequence, or -1. If it returns a positive value, then successive calls to underflow() will not return traits::eof() until at least that number of characters have been extracted from the stream. If showmanyc() returns -1, then calls to underflow() or uflow() will fail.

Default behavior: Returns zero.

Remarks: Uses traits::eof().

```cpp
streamsize xsgetn(char_type* s, streamsize n);
```

Effects: Assigns up to n characters to successive elements of the array whose first element is designated by s. The characters assigned are read from the input sequence as if by repeated calls to sbumpc(). Assigning stops when either n characters have been assigned or a call to sbumpc() would return traits::eof().

Returns: The number of characters assigned.

Remarks: Uses traits::eof().

---

296) The morphemes of showmanyc are "es-how-many-see", not "show-manic".
297) underflow or uflow might fail by throwing an exception prematurely. The intention is not only that the calls will not return eof() but that they will return "immediately".
298) Classes derived from basic_streambuf can provide more efficient ways to implement xsgetn() and xsputn() by overriding these definitions from the base class.
int_type underflow();

Returns: traits::to_int_type(c), where c is the first character of the pending sequence, without moving the input sequence position past it. If the pending sequence is null then the function returns traits::eof() to indicate failure.

Remarks: The public members of basic_streambuf call this virtual function only if gptr() is null or gptr() >= egptr().

The pending sequence of characters is defined as the concatenation of
- the empty sequence if gptr() is null, otherwise the characters in [gptr(), egptr()), followed by
- some (possibly empty) sequence of characters read from the input sequence.

The result character is the first character of the pending sequence if it is non-empty, otherwise the next character that would be read from the input sequence.

The backup sequence is the empty sequence if eback() is null, otherwise the characters in [eback(), gptr()).

Effects: The function sets up the gptr() and egptr() such that if the pending sequence is non-empty, then egptr() is non-null and the characters in [gptr(), egptr()) are the characters in the pending sequence, otherwise either gptr() is null or gptr() == egptr().

If eback() and gptr() are non-null then the function is not constrained as to their contents, but the "usual backup condition" is that either
- the backup sequence contains at least gptr() - eback() characters, in which case the characters in [eback(), gptr()) agree with the last gptr() - eback() characters of the backup sequence, or
- the characters in [gptr() - n, gptr()) agree with the backup sequence (where n is the length of the backup sequence).

Default behavior: Returns traits::eof().

int_type uflow();

Preconditions: The constraints are the same as for underflow(), except that the result character is transferred from the pending sequence to the backup sequence, and the pending sequence is not empty before the transfer.

Default behavior: Calls underflow(). If underflow() returns traits::eof(), returns traits::eof(). Otherwise, returns the value of traits::to_int_type(*gptr()) and increment the value of the next pointer for the input sequence.

Returns: traits::eof() to indicate failure.

29.6.3.4.4 Putback [streambuf.virt.pback]

int_type pbackfail(int_type c = traits::eof());

Remarks: The public functions of basic_streambuf call this virtual function only when gptr() is null, gptr() == eback(), or traits::eq(traits::to_char_type(c), gptr()[-1]) returns false. Other calls shall also satisfy that constraint.

The pending sequence is defined as for underflow(), with the modifications that
- If traits::eq_int_type(c, traits::eof()) returns true, then the input sequence is backed up one character before the pending sequence is determined.
- If traits::eq_int_type(c, traits::eof()) returns false, then c is prepended. Whether the input sequence is backed up or modified in any other way is unspecified.

Returns: traits::eof() to indicate failure. Failure may occur because the input sequence could not be backed up, or if for some other reason the pointers could not be set consistent with the constraints. pbackfail() is called only when put back has really failed.

Returns some value other than traits::eof() to indicate success.

Postconditions: On return, the constraints of gptr(), eback(), and pptr() are the same as for underflow().

Default behavior: Returns traits::eof().
29.6.3.4.5 Put area

streamsize xsputn(const char_type* s, streamsize n);

Effects: Writes up to \( n \) characters to the output sequence as if by repeated calls to `sputc(c)`. The characters written are obtained from successive elements of the array whose first element is designated by `s`. Writing stops when either \( n \) characters have been written or a call to `sputc(c)` would return `traits::eof()`. It is unspecified whether the function calls `overflow()` when `pptr() == epptr()` becomes true or whether it achieves the same effects by other means.

Returns: The number of characters written.

int_type overflow(int_type c = traits::eof());

Effects: Consumes some initial subsequence of the characters of the pending sequence. The pending sequence is defined as the concatenation of

- the empty sequence if `pbase()` is null, otherwise the `pptr()` - `pbase()` characters beginning at `pbase()`, followed by
- the empty sequence if `traits::eq_int_type(c, traits::eof())` returns true, otherwise the sequence consisting of `c`.

Remarks: The member functions `sputc()` and `sputn()` call this function in case that no room can be found in the put buffer enough to accommodate the argument character sequence.

Preconditions: Every overriding definition of this virtual function obeys the following constraints:

- The effect of consuming a character on the associated output sequence is specified.\(^{299}\)
- Let \( r \) be the number of characters in the pending sequence not consumed. If \( r \) is nonzero then `pbase()` and `pptr()` are set so that: `pptr() - pbase() == r` and the \( r \) characters starting at `pbase()` are the associated output stream. In case \( r \) is zero (all characters of the pending sequence have been consumed) then either `pbase()` is set to nullptr, or `pbase()` and `pptr()` are both set to the same non-null value.\(^{5.3}\)
- The function may fail if either appending some character to the associated output stream fails or if it is unable to establish `pbase()` and `pptr()` according to the above rules.

Returns: `traits::eof()` or throws an exception if the function fails. Otherwise, returns some value other than `traits::eof()` to indicate success.\(^{300}\)

Default behavior: Returns `traits::eof()`.

29.7 Formatting and manipulators

29.7.1 Header `<istream>` synopsis

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_istream;

    using istream = basic_istream<char>;
    using wistream = basic_istream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    class basic_iostream;

    using iostream = basic_iostream<char>;
    using wiostream = basic_iostream<wchar_t>;

    template<class charT, class traits>
    basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

    template<class Istream, class T>
    Istream&& operator>>(Istream&& is, T&& x);
}
```

\(^{299}\) That is, for each class derived from an instance of `basic_streambuf` in this Clause (29.8.2, 29.9.2), a specification of how consuming a character effects the associated output sequence is given. There is no requirement on a program-defined class.

\(^{300}\) Typically, `overflow` returns `c` to indicate success, except when `traits::eq_int_type(c, traits::eof())` returns true, in which case it returns `traits::not_eof(c)`.
29.7.2 Header <ostream> synopsis

}

29.7.4 Input streams

The header <iostream> defines two types and a function signature that control input from a stream buffer along with a function template that extracts from stream rvalues.
29.7.4.1  Class template \texttt{basic\_istream}[\textit{istream}]

namespace std {
    template<class \texttt{charT}, class \texttt{traits} = char_traits<\texttt{charT}>}
    class basic_istream : virtual public basic_ios<charT, traits> {
        public:
            // types (inherited from basic_ios (29.5.5))
            using \texttt{char\_type} = charT;
            using \texttt{int\_type} = typename \texttt{traits::int\_type};
            using \texttt{pos\_type} = typename \texttt{traits::pos\_type};
            using \texttt{off\_type} = typename \texttt{traits::off\_type};
            using \texttt{traits\_type} = \texttt{traits};

            // 29.7.4.1.1, constructor/destructor
            explicit basic_istream(basic_streambuf<charT, traits>* sb);
            virtual ~basic_istream();

            // 29.7.4.1.3, prefix/suffix
            class sentry;

            // 29.7.4.2, formatted input
            basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& (*pf)(basic_istream<charT, traits>&&));
            basic_istream<charT, traits>&
                operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));
            basic_istream<charT, traits>&
                operator>>(ios_base& (*pf)(ios_base&));
            basic_istream<charT, traits>& operator>>(bool& n);
            basic_istream<charT, traits>& operator>>(short& n);
            basic_istream<charT, traits>& operator>>(unsigned short& n);
            basic_istream<charT, traits>& operator>>(int& n);
            basic_istream<charT, traits>& operator>>(unsigned int& n);
            basic_istream<charT, traits>& operator>>(long& n);
            basic_istream<charT, traits>& operator>>(unsigned long& n);
            basic_istream<charT, traits>& operator>>(long long& n);
            basic_istream<charT, traits>& operator>>(unsigned long long& n);
            basic_istream<charT, traits>& operator>>(float& f);
            basic_istream<charT, traits>& operator>>(double& f);
            basic_istream<charT, traits>& operator>>(long double& f);

            basic_istream<charT, traits>& operator>>(void*& p);
            basic_istream<charT, traits>& operator>>(basic_streambuf<char_type, traits>* sb);

            // 29.7.4.3, unformatted input
            streamsize gcount() const;
            int_type get();
            basic_istream<charT, traits>& get(char_type& c);
            basic_istream<charT, traits>& get(char_type* s, streamsize n);
            basic_istream<charT, traits>& get(char_type* s, streamsize n, char_type delim);
            basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>&& sb);
            basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb, char_type delim);

            basic_istream<charT, traits>& getline(char_type* s, streamsize n);
            basic_istream<charT, traits>& getline(char_type* s, streamsize n, char_type delim);

            basic_istream<charT, traits>& ignore(streamsize n = 1, int_type delim = traits::eof());
            int_type peek();
            basic_istream<charT, traits>& read (char_type* s, streamsize n);
            streamsize readsome(char_type* s, streamsize n);

            basic_istream<charT, traits>& putback(char_type c);
            basic_istream<charT, traits>& unget();
            int sync();
The class template \texttt{basic\_istream} defines a number of member function signatures that assist in reading and interpreting input from sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the \textit{formatted input functions} (or \textit{extractors}) and the \textit{unformatted input functions}. Both groups of input functions are described as if they obtain (or extract) input characters by calling \texttt{rdbuf()->sbumpc()} or \texttt{rdbuf()->sgetc()}. They may use other public members of \texttt{istream}.

If \texttt{rdbuf()->sbumpc()} or \texttt{rdbuf()->sgetc()} returns \texttt{traits::eof()}, then the input function, except as explicitly noted otherwise, completes its actions and does \texttt{setstate(eofbit)}, which may throw \texttt{ios\_base::failure} (29.5.5.4), before returning.

If one of these called functions throws an exception, then unless explicitly noted otherwise, the input function sets \texttt{badbit} in the error state. If \texttt{badbit} is set in \texttt{exceptions()}, the input function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

\textbf{29.7.4.1.1 Constructors} \hfill \cite{istream.cons}

\begin{verbatim}
explicit basic_istream(basic_streambuf<charT, traits>* sb);
\end{verbatim}

\textit{Effects:} Initializes the base class subobject with \texttt{basic\_ios::init(sb)} (29.5.5.2).

\textit{Postconditions:} \texttt{gcount()} == 0.

\begin{verbatim}
basic_istream(basic_istream&& rhs);
\end{verbatim}

\textit{Effects:} Default constructs the base class, copies the \texttt{gcount()} from rhs, calls \texttt{basic\_ios<char\_T, traits>::move(rhs)} to initialize the base class, and sets the \texttt{gcount()} for rhs to 0.

\textit{Remarks:} Does not perform any operations of \texttt{rdbuf()}.

\textbf{29.7.4.1.2 Assignment and swap} \hfill \cite{istream.assign}

\begin{verbatim}
basic_istream& operator=(basic_istream&& rhs);
\end{verbatim}

\textit{Effects:} Equivalent to: \texttt{swap(rhs)}.
Returns: *this.

void swap(basic_istream& rhs);

Effects: Calls basic_ios<charT, traits>::swap(rhs). Exchanges the values returned by gcount() and rhs.gcount().

29.7.4.1.3 Class basic_istream::sentry

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_istream<charT, traits>::sentry {
        bool ok_; // exposition only
    public:
        explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);
        ~sentry();
        explicit operator bool() const { return ok_; }
        sentry(const sentry&) = delete;
        sentry& operator=(const sentry&) = delete;
    };
}

The class sentry defines a class that is responsible for doing exception safe prefix and suffix operations.

explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);

Effects: If is.good() is false, calls is.setstate(failbit). Otherwise, prepares for formatted or unformatted input. First, if is.tie() is not a null pointer, the function calls is.tie()->flush() to synchronize the output sequence with any associated external C stream. Except that this call can be suppressed if the put area of is.tie() is empty. Further an implementation is allowed to defer the call to flush until a call of is.rdbuf()->underflow() occurs. If no such call occurs before the sentry object is destroyed, the call to flush may be eliminated entirely. If noskipws is zero and is.flags() & ios_base::skipws is nonzero, the function extracts and discards each character as long as the next available input character c is a whitespace character. If is.rdbuf()->sbumpc() or is.rdbuf()->sgetc() returns traits::eof(), the function calls setstate(failbit | eofbit) (which may throw ios_base::failure).

Remarks: The constructor uses the currently imbued locale in is, to determine whether the next input character is whitespace or not.

To decide if the character c is a whitespace character, the constructor performs as if it executes the following code fragment:

    const ctype<charT>& ctype = use_facet<ctype<charT>>(is.getloc());
    if (ctype.is(ctype.space, c) != 0)
        // c is a whitespace character.

If, after any preparation is completed, is.good() is true, ok_ != false otherwise, ok_ == false. During preparation, the constructor may call setstate(failbit) (which may throw ios_base::failure (29.5.5.4)).

    ~sentry();

Effects: None.

explicit operator bool() const;

Returns: ok_.

29.7.4.2 Formatted input functions

29.7.4.2.1 Common requirements

Each formatted input function begins execution by constructing an object of class sentry with the noskipws (second) argument false. If the sentry object returns true, when converted to a value of type bool, the function endeavors to obtain the requested input. If an exception is thrown during input then ios_base::badbit is turned on in

---

301) This will be possible only in functions that are part of the library. The semantics of the constructor used in user code is as specified.
302) The sentry constructor and destructor can also perform additional implementation-dependent operations.
303) This is done without causing an ios_base::failure to be thrown.
*this's error state. If (exceptions()&badbit) != 0 then the exception is rethrown. In any case, the formatted input function destroys the sentry object. If no exception has been thrown, it returns *this.

### 29.7.4.2.2 Arithmetic extractors

[istream.formatted.arithmetic]

```cpp
operator>>(unsigned short& val);
operator>>(unsigned int& val);
operator>>(long& val);
operator>>(unsigned long& val);
operator>>(long long& val);
operator>>(unsigned long long& val);
operator>>(float& val);
operator>>(double& val);
operator>>(long double& val);
operator>>(bool& val);
operator>>(void*& val);
```

1 As in the case of the inserters, these extractors depend on the locale's `num_get<>` ([28.4.2.1]) object to perform parsing the input stream data. These extractors behave as formatted input functions (as described in 29.7.4.2.1). After a sentry object is constructed, the conversion occurs as if performed by the following code fragment:

```cpp
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
iosstate err = ios_base::goodbit;
use_facet<numget>(loc).get(*this, 0, *this, err, val);
setstate(err);
```

In the above fragment, `loc` stands for the private member of the `basic_ios` class. [Note: The first argument provides an object of the `istreambuf_iterator` class which is an iterator pointed to an input stream. It bypasses istreams and uses streambufs directly. — end note] Class `locale` relies on this type as its interface to `istream`, so that it does not need to depend directly on `istream`.

```cpp
operator>>(short& val);
```

2 The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```cpp
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
iosstate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<short>::min()) {
  err |= ios_base::failbit;
  val = numeric_limits<short>::min();
} else if (numeric_limits<short>::max() < lval) {
  err |= ios_base::failbit;
  val = numeric_limits<short>::max();
} else
  val = static_cast<short>(lval);
setstate(err);
```

```cpp
operator>>(int& val);
```

3 The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```cpp
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
iosstate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<int>::min()) {
  err |= ios_base::failbit;
  val = numeric_limits<int>::min();
} else if (numeric_limits<int>::max() < lval) {
  err |= ios_base::failbit;
  val = numeric_limits<int>::max();
} else
  val = static_cast<int>(lval);
setstate(err);
```
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& (*pf)(basic_istream<charT, traits>&));

    Effects: None. This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).
    Returns: pf(*this).

downstream

basic_istream<charT, traits>& operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));

    Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).
    Returns: *this.

downstream

basic_istream<charT, traits>& operator>>(ios_base& (*pf)(ios_base&));

    Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).
    Returns: *this.

downstream

basic_istream<charT, traits>& operator>>(ios_base& (*pf)(ios_base&));

    Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).
    Returns: *this.

downstream

basic_istream<charT, traits>& operator>>(ios_base& (*pf)(ios_base&));

    Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).
    Returns: *this.

downstream

template<class charT, class traits, size_t N>

    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT (&s)[N]);

template<class traits, size_t N>

    basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char (&s)[N]);

template<class traits, size_t N>

    basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char (&s)[N]);

    Effects: Behaves like a formatted input member (as described in 29.7.4.2.1) of in. After a sentry object is constructed, operator>> extracts characters and stores them into s. If width() is greater than zero, n is min(size_t(width()), N). Otherwise n is N. n is the maximum number of characters stored.

Characters are extracted and stored until any of the following occurs:

(8.1) n-1 characters are stored;
(8.2) end of file occurs on the input sequence;
(8.3) letting ct be use_facet<ctype<charT>>(in.getloc()), ct.is(ct.space, c) is true.

operator>> then stores a null byte (charT()) in the next position, which may be the first position if no characters were extracted. operator>> then calls width(0).

If the function extracted no characters, it calls setstate(failbit), which may throw ios_base::failure (29.5.5.4).

Returns: in.

downstream

basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT& c);

basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char& c);

basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char& c);

    Effects: Behaves like a formatted input member (as described in 29.7.4.2.1) of in. After a sentry object is constructed a character is extracted from in, if one is available, and stored in c. Otherwise, the function calls in.setstate(failbit).
    Returns: in.

downstream

downstream

basic_istream<charT, traits>& operator>>(basic_streambuf<charT, traits>* sb);

    Effects: Behaves as an unformatted input function (29.7.4.3). If sb is null, calls setstate(failbit), which may throw ios_base::failure (29.5.5.4). After a sentry object is constructed, extracts characters from *this and inserts them in the output sequence controlled by sb. Characters are extracted and inserted until any of the following occurs:

(14.1) end-of-file occurs on the input sequence;

304) See, for example, the function signature ws(basic_istream&) (29.7.4.4).
305) See, for example, the function signature dec(ios_base&) (29.5.6.3).
— inserting in the output sequence fails (in which case the character to be inserted is not extracted);
— an exception occurs (in which case the exception is caught).

If the function inserts no characters, it calls setstate(failbit), which may throw ios_base::failure (29.5.5.4). If it inserted no characters because it caught an exception thrown while extracting characters from *this and failbit is set in exceptions() (29.5.5.4), then the caught exception is rethrown.

Returns: *this.

29.7.4.3 Unformatted input functions
[istream.unformatted]

Each unformatted input function begins execution by constructing an object of class sentry with the default argument noskipws (second) argument true. If the sentry object returns true, when converted to a value of type bool, the function endeavors to obtain the requested input. Otherwise, if the sentry object returns false, when converted to a value of type bool, the function returns without attempting to obtain any input. In either case the number of extracted characters is set to 0; unformatted input functions taking a character array of nonzero size as an argument shall also store a null character (using charT()) in the first location of the array. If an exception is thrown during input then ios_base::badbit is turned on in *this’s error state. (Exceptions thrown from basic_ios<>::clear() are not caught or rethrown.) If (exceptions()&badbit) != 0 then the exception is rethrown. It also counts the number of characters extracted. If no exception has been thrown it ends by storing the count in a member object and returning the value specified. In any event the sentry object is destroyed before leaving the unformatted input function.

streamsize gcount() const;

Effects: None. This member function does not behave as an unformatted input function (as described above).

Returns: The number of characters extracted by the last unformatted input member function called for the object.

int_type get();

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts a character c, if one is available. Otherwise, the function calls setstate(failbit), which may throw ios_base::failure (29.5.5.4).

Returns: c if available, otherwise traits::eof().

basic_istream<charT, traits>& get(char_type& c);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts a character, if one is available, and assigns it to c. Otherwise, the function calls setstate(failbit) (which may throw ios_base::failure (29.5.5.4)).

Returns: *this.

basic_istream<charT, traits>& get(char_type* s, streamsize n, char_type delim);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by s. Characters are extracted and stored until any of the following occurs:

— n is less than one or n - 1 characters are stored;
— end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit));
— traits::eq(c, delim) for the next available input character c (in which case c is not extracted).

If the function stores no characters, it calls setstate(failbit) (which may throw ios_base::failure (29.5.5.4)). In any case, if n is greater than zero it then stores a null character into the next successive location of the array.

Returns: *this.

basic_istream<charT, traits>& get(char_type* s, streamsize n);

Effects: Calls get(s, n, widen('\n')).
Returns: Value returned by the call.

basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb, char_type delim);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and inserts them in the output sequence controlled by sb. Characters are extracted and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- traits::eq(c, delim) for the next available input character c (in which case c is not extracted);
- an exception occurs (in which case, the exception is caught but not rethrown).

If the function inserts no characters, it calls setstate(failbit), which may throw ios_base::failure (29.5.5.4).

Returns: *this.

basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb);

Effects: Calls get(sb, widen('\n')).

Returns: Value returned by the call.

basic_istream<charT, traits>& getline(char_type* s, streamsize n, char_type delim);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by s. Characters are extracted and stored until one of the following occurs:

1. end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit));
2. traits::eq(c, delim) for the next available input character c (in which case the input character is extracted but not stored);[^310]
3. n is less than one or n - 1 characters are stored (in which case the function calls setstate(failbit)).[^310]

These conditions are tested in the order shown.[^310]

If the function extracts no characters, it calls setstate(failbit) (which may throw ios_base::failure (29.5.5.4)).[^310]

In any case, if n is greater than zero, it then stores a null character (using charT()) into the next successive location of the array.

Returns: *this.

[Example:]

```cpp
#include <iostream>

int main() {
  using namespace std;
  const int line_buffer_size = 100;

  char buffer[line_buffer_size];
  int line_number = 0;
  while (cin.getline(buffer, line_buffer_size, '\n') || cin.gcount()) {
    int count = cin.gcount();
    if (cin.eof())
      cout << "Partial final line"; // cin.fail() is false
    else if (cin.fail()) {
      cout << "Partial long line";
      cin.clear(cin.rdbuf()); // "ios_base::failbit";
    } else {
```

[^309]: Note that this function is not overloaded on types signed char and unsigned char.

[^310]: Since the final input character is “extracted”, it is counted in the gcount(), even though it is not stored.

[^311]: This allows an input line which exactly fills the buffer, without setting failbit. This is different behavior than the historical AT&T implementation.

[^312]: This implies an empty input line will not cause failbit to be set.
count--;
// Don't include newline in count
    cout << "Line " << ++line_number;
}
    cout << " (" << count << " chars): " << buffer << endl;
}

— end example]

basic_istream<charT, traits>& getline(char_type* s, streamsize n);

Returns: getline(s, n, widen(\"n\")

basic_istream<charT, traits>& ignore(streamsize n = 1, int_type delim = traits::eof());

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and discards them. Characters are extracted until any of the following occurs:

  — n != numeric_limits<streamsize>::max() (17.3.5) and n characters have been extracted so far
  — end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit), which may throw ios_base::failure (29.5.5.4));
  — traits::eq_int_type(trait::to_int_type(c), delim) for the next available input character c (in which case c is extracted).

[Note: The last condition will never occur if traits::eq_int_type(delim, traits::eof()).—end note]

Returns: *this.

int_type peek();

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, reads but does not extract the current input character.

Returns: traits::eof() if good() is false. Otherwise, returns rdbuf()->sgetc().

basic_istream<charT, traits>& read(char_type* s, streamsize n);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by s. Characters are extracted and stored until either of the following occurs:

  — n characters are stored;
  — end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit | eofbit), which may throw ios_base::failure (29.5.5.4)).

Returns: *this.

streamsize readsome(char_type* s, streamsize n);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by s. If rdbuf() -> in_avail() == -1, calls setstate(eofbit) (which may throw ios_base::failure (29.5.5.4)), and extracts no characters; if rdbuf() -> in_avail() == 0, extracts no characters
  — If rdbuf() -> in_avail() > 0, extracts min(rdbuf() -> in_avail(), n)).

Returns: The number of characters extracted.

basic_istream<charT, traits>& putback(char_type c);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit. After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. If rdbuf() is not null, calls rdbuf()->sputbackc(c). If rdbuf() is null, or if sputbackc returns traits::eof(), calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to gcount() is 0. —end note]

313) Note that this function is not overloaded on types signed char and unsigned char.
Returns: *this.

basic_istream<charT, traits>& unget();

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit. After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. If rdbuf() is not null, calls rdbuf()->sungetc(). If rdbuf() is null, or if sungetc returns traits::eof(), calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to gcount() is 0. — end note]

Returns: *this.

int sync();

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if rdbuf() is a null pointer, returns -1. Otherwise, calls rdbuf()->pubsync() and, if that function returns -1 calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)), and returns -1. Otherwise, returns zero.

pos_type tellg();

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to gcount().

Returns: After constructing a sentry object, if fail() != false, returns pos_type(-1) to indicate failure. Otherwise, returns rdbuf()->pubseekoff(0, cur, in).

basic_istream<charT, traits>& seekg(pos_type pos);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit, it does not count the number of characters extracted, and it does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != false, executes rdbuf()->pubseekpos(pos, ios_base::in). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

basic_istream<charT, traits>& seekg(off_type off, ios_base::seekdir dir);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit, does not count the number of characters extracted, and does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != false, executes rdbuf()->pubseekoff(off, dir, ios_base::in). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

29.7.4.4 Standard basic_istream manipulators

Each instantiation of the function template specified in this subclause is a designated addressable function (16.5.4.2.1).

template<class charT, class traits>
basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

Effects: Behaves as an unformatted input function (29.7.4.3), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to is.gcount(). After constructing a sentry object extracts characters as long as the next available character c is whitespace or until there are no more characters in the sequence. Whitespace characters are distinguished with the same criterion as used by sentry::sentry (29.7.4.1.3). If ws stops extracting characters because there are no more available it sets eofbit, but not failbit.

Returns: is.

29.7.4.5 Rvalue stream extraction

template<class Istream, class T>
Istream&& operator>>(Istream&& is, T&& x);

Constraints: The expression is >> std::forward<T>(x) is well-formed when treated as an unevaluated operand and Istream is publicly and unambiguously derived from ios_base.
The class template `basic_iostream` inherits a number of functions that allow reading input and writing output to sequences controlled by a stream buffer.

### 29.7.4.6.1 Constructors

```cpp
explicit basic_iostream(basic_streambuf<charT, traits>* sb);
```

1. **Effects**: Initializes the base class subobjects with `basic_istream<charT, traits>(sb)` (29.7.4.1) and `basic_ostream<charT, traits>(sb)` (29.7.5.1).

2. **Postconditions**: `rdbuf() == sb` and `gcount() == 0`.

```cpp
basic_iostream(basic_iostream&& rhs);
```

1. **Effects**: Move constructs from the rvalue `rhs` by constructing the `basic_istream` base class with `move(rhs)`.

### 29.7.4.6.2 Destructor

```cpp
virtual ~basic_iostream();
```

1. **Remarks**: Does not perform any operations on `rdbuf()`.

### 29.7.4.6.3 Assignment and swap

```cpp
basic_iostream& operator=(basic_iostream&& rhs);
```

1. **Effects**: Equivalent to: `swap(rhs)`.

```cpp
void swap(basic_iostream& rhs);
```

1. **Effects**: Calls `basic_istream<charT, traits>::swap(rhs)`.

---

© ISO/IEC
29.7.5 Output streams

The header `<ostream>` defines a type and several function signatures that control output to a stream buffer along with a function template that inserts into stream rvalues.

29.7.5.1 Class template basic_ostream

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ostream : virtual public basic_ios<charT, traits> {
        public:
            // types (inherited from basic_ios (29.5.5))
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

            // 29.7.5.1.1, constructor/destructor
            explicit basic_ostream(basic_streambuf<char_type, traits>* sb);
            virtual ~basic_ostream();

            // 29.7.5.1.3, prefix/suffix
            class sentry;

            // 29.7.5.2, formatted output
            basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&&));
            basic_ostream<charT, traits>&
                operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));
            basic_ostream<charT, traits>&
                operator<<(ios_base& (*pf)(ios_base&));

template<class traits>
basic_ostream<wchar_t, traits>& operator<<(basic_ostream<wchar_t, traits>&, char32_t) = delete;

§ 29.7.5.1
The class template `basic_ostream` defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the formatted output functions (or inserters) and the unformatted output functions. Both groups of output functions generate (or insert) output characters by actions equivalent to calling `rdbuf()->sputc(int_type)`. They may use other public members of `basic_ostream` except that they shall not invoke any virtual members of `rdbuf()` except `overflow()`, `xsputn()`, and `sync()`.

If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets `badbit` in the error state. If `badbit` is set in `exceptions()`, the output function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

[Note: The deleted overloads of `operator<<` prevent formatting characters as integers and strings as pointers. — end note]

### 29.7.5.1.1 Constructors

```cpp
template<class traits>
    basic_ostream<wchar_t, traits>&
    operator<<(basic_ostream<wchar_t, traits>&, const char16_t*) = delete;

template<class traits>
    basic_ostream<wchar_t, traits>&
    operator<<(basic_ostream<wchar_t, traits>&, const char32_t*) = delete;
```

1. The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.
explicit sentry(basic_ostream<charT, traits>& os);

2 If os.good() is nonzero, prepares for formatted or unformatted output. If os.tie() is not a null pointer, calls os.tie()->flush().\(^{314}\)

3 If, after any preparation is completed, os.good() is true, ok_ == true otherwise, ok_ == false. During preparation, the constructor may call setstate(failbit) (which may throw ios_base::failure (29.5.5.4)).\(^{315}\)

`~sentry();

4 If (os.flags() & ios_base::unitbuf) && !uncaught_exceptions() && os.good() is true, calls os.rdbuf()->pubsync(). If that function returns -1, sets badbit in os.rdstate() without propagating an exception.

explicit operator bool() const;

Effects: Returns ok_.

29.7.5.1.4 Seek members \[ostream.seeks\]

1 Each seek member function begins execution by constructing an object of class sentry. It returns by destroying the sentry object.

pos_type tellp();

2 Returns: If fail() != false, returns pos_type(-1) to indicate failure. Otherwise, returns rdbuf()->pubseekoff(0, cur, out).

basic_ostream<charT, traits>& seekp(pos_type pos);

3 Effects: If fail() != true, executes rdbuf()->pubseekpos(pos, ios_base::out). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

4 Returns: *this.

basic_ostream<charT, traits>& seekp(off_type off, ios_base::seekdir dir);

5 Effects: If fail() != true, executes rdbuf()->pubseekoff(off, dir, ios_base::out). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

6 Returns: *this.

29.7.5.2 Formatted output functions \[ostream.formatted\]

29.7.5.2.1 Common requirements \[ostream.formatted:reqmts\]

1 Each formatted output function begins execution by constructing an object of class sentry. If this object returns true when converted to a value of type bool, the function endeavors to generate the requested output. If the generation fails, then the formatted output function does setstate(ios_base::failbit), which might throw an exception. If an exception is thrown during output, then ios_base::badbit is turned on\(^{316}\) in *this’s error state. If (exceptions()&badbit) != 0 then the exception is rethrown. Whether or not an exception is thrown, the sentry object is destroyed before leaving the formatted output function. If no exception is thrown, the result of the formatted output function is *this.

The descriptions of the individual formatted output functions describe how they perform output and do not mention the sentry object.

2 If a formatted output function of a stream os determines padding, it does so as follows. Given a charT character sequence seq where charT is the character type of the stream, if the length of seq is less than os.width(), then enough copies of os.fill() are added to this sequence as necessary to pad to a width of os.width() characters. If (os.flags() & ios_base::adjustfield) == ios_base::left is true, the fill characters are placed after the character sequence; otherwise, they are placed before the character sequence.

29.7.5.2.2 Arithmetic inserters \[ostream.inserters.arithmetic\]

operator<<(bool val);
operator<<(short val);

\(^{314}\)The call os.tie()->flush() does not necessarily occur if the function can determine that no synchronization is necessary.

\(^{315}\)The sentry constructor and destructor can also perform additional implementation-dependent operations.

\(^{316}\)without causing an ios_base::failure to be thrown.
operator<<(unsigned short val);
operator<<(int val);
operator<<(unsigned int val);
operator<<(long val);
operator<<(unsigned long val);
operator<<(long long val);
operator<<(unsigned long long val);
operator<<(float val);
operator<<(double val);
operator<<(long double val);
operator<<(const void* val);

1 Effects: The classes num_get<> and num_put<> handle locale-dependent numeric formatting and parsing. These inserter functions use the imbued locale value to perform numeric formatting. When val is of type bool, long, unsigned long, long, unsigned long, double, long double, or const void*, the formatting conversion occurs as if it performed the following code fragment:

```cpp
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    ,(getloc()).put(*this, *this, fill(), val).failed();
```

When val is of type short the formatting conversion occurs as if it performed the following code fragment:

```cpp
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    ,(getloc()).put(*this, *this, fill(),
    baseflags == ios_base::oct || baseflags == ios_base::hex
    ? static_cast<long>(static_cast<unsigned short>(val))
    : static_cast<long>(val)).failed();
```

When val is of type int the formatting conversion occurs as if it performed the following code fragment:

```cpp
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    ,(getloc()).put(*this, *this, fill(),
    baseflags == ios_base::oct || baseflags == ios_base::hex
    ? static_cast<long>(static_cast<unsigned int>(val))
    : static_cast<long>(val)).failed();
```

When val is of type unsigned short or unsigned int the formatting conversion occurs as if it performed the following code fragment:

```cpp
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    ,(getloc()).put(*this, *this, fill(),
    static_cast<unsigned long>(val)).failed();
```

When val is of type float the formatting conversion occurs as if it performed the following code fragment:

```cpp
bool failed = use_facet<
    num_put<charT, ostreambuf_iterator<charT, traits>>
    ,(getloc()).put(*this, *this, fill(),
    static_cast<double>(val)).failed();
```

2 The first argument provides an object of the ostreambuf_iterator<> class which is an iterator for class basic_ostream<>. It bypasses streams and uses streambufs directly. Class locale relies on these types as its interface to iostreams, since for flexibility it has been abstracted away from direct dependence on ostream. The second parameter is a reference to the base class subobject of type ios_base. It provides formatting specifications such as field width, and a locale from which to obtain other facets. If failed is true then does setstate(badbit), which may throw an exception, and returns.

Returns: *this.

29.7.5.2.3 basic_ostream::operator<<

```cpp
basic_ostream<charT, traits>&
operator<<((basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&));
```

1 Effects: None. Does not behave as a formatted output function (as described in 29.7.5.2.1).
Returns: \(\text{pf}(*\text{this})\).

```
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&));
```

Effects: Calls \(\text{pf}(*\text{this})\). This inserter does not behave as a formatted output function (as described in 29.7.5.2.1).

Returns: \(*\text{this}\).

```
basic_ostream<charT, traits>&
operator<<(ios_base& (*pf)(ios_base&));
```

Effects: Calls \(\text{pf}(*\text{this})\). This inserter does not behave as a formatted output function (as described in 29.7.5.2.1).

Returns: \(*\text{this}\).

```
basic_ostream<charT, traits>&
operator<<(basic_streambuf<charT, traits>* sb);
```

Effects: Behaves as an unformatted output function (29.7.5.3). After the sentry object is constructed, if \(sb\) is null calls `setstate(badbit)` (which may throw `ios_base::failure`).

Gets characters from \(sb\) and inserts them in \(*\text{this}\). Characters are read from \(sb\) and inserted until any of the following occurs:

1. End-of-file occurs on the input sequence;
2. Inserting in the output sequence fails (in which case the character to be inserted is not extracted);
3. An exception occurs while getting a character from \(sb\).

If the function inserts no characters, it calls \(\text{setstate}(	ext{failbit})\) (which may throw `ios_base::failure` (29.5.5.4)). If an exception was thrown while extracting a character, the function sets \(\text{failbit}\) in the error state, and if \(\text{failbit}\) is set in \(\text{exceptions()}\) the caught exception is rethrown.

Returns: \(*\text{this}\).

```
basic_ostream<charT, traits>&
operator>>(nullptr_t);
```

Effects: Equivalent to:

```
return *this << std::endl;
```

where \(s\) is an implementation-defined NTCTS (16.3.18).

### 29.7.5.2.4 Character inserter function templates

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& out, charT c);
```

Effects: Behaves as a formatted output function (29.7.5.2.1) of \(out\). Constructs a character sequence \(seq\). If \(c\) has type `char` and the character type of the stream is not `char`, then \(seq\) consists of `out.widen(c)`; otherwise \(seq\) consists of \(c\). Determines padding for \(seq\) as described in 29.7.5.2.1. Inserts \(seq\) into \(out\). Calls `os.width(0)`.

Returns: \(out\).

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& out, const charT* s);
```

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& out, const char* s);
```

317) See, for example, the function signature `endl` (basic_ostream) (29.7.5.4).

318) See, for example, the function signature `dec` (ios_base) (29.5.6.3).
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const signed char* s);

Preconditions: s is not a null pointer.

Effects: Behaves like a formatted inserter (as described in 29.7.5.2.1) of out. Creates a character sequence seq of n characters starting at s, each widened using out.widen() (29.5.5.3), where n is the number that would be computed as if by:

(4.1) traits::length(s) for the overload where the first argument is of type basic_ostream<charT, traits>& and the second is of type const charT*, and also for the overload where the first argument is of type basic_ostream<char, traits>& and the second is of type const char*.
(4.2) char_traits<char>::length(s) for the overload where the first argument is of type basic_ostream<char, traits>& and the second is of type const char*.
(4.3) traits::length(reinterpret_cast<const char*>(s)) for the other two overloads.

Determines padding for seq as described in 29.7.5.2.1. Inserts seq into out. Calls width(0).

Returns: out.

29.7.5.3 Unformatted output functions

Each unformatted output function begins execution by constructing an object of class sentry. If this object returns true, while converting to a value of type bool, the function endeavors to generate the requested output. If an exception is thrown during output, then ios_base::badbit is turned on in *this’s error state. If (exceptions() & badbit) != 0 then the exception is rethrown. In any case, the unformatted output function ends by destroying the sentry object, then, if no exception was thrown, returning the value specified for the unformatted output function.

basic_ostream<charT, traits>& put(char_type c);

Effects: Behaves as an unformatted output function (as described above). After constructing a sentry object, inserts the character c, if possible. Otherwise, calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)).

Returns: *this.

basic_ostream& write(const char_type* s, streamsize n);

Effects: Behaves as an unformatted output function (as described above). After constructing a sentry object, obtains characters to insert from successive locations of an array whose first element is designated by s. Characters are inserted until either of the following occurs:

(5.1) n characters are inserted;
(5.2) inserting in the output sequence fails (in which case the function calls setstate(badbit), which may throw ios_base::failure (29.5.5.4)).

Returns: *this.

basic_ostream& flush();

Effects: Behaves as an unformatted output function (as described above). If rdbuf() is not a null pointer, constructs a sentry object. If this object returns true when converted to a value of type bool the function calls rdbuf()->pubsync(). If that function returns -1 calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)). Otherwise, if the sentry object returns false, does nothing.

Returns: *this.

29.7.5.4 Standard manipulators

Each instantiation of any of the function templates specified in this subclause is a designated addressable function (16.5.4.2.1).

319) without causing an ios_base::failure to be thrown.
320) Note that this function is not overloaded on types signed char and unsigned char.
321) Note that this function is not overloaded on types signed char and unsigned char.
template<class charT, class traits>
  basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);

  Effects: Calls os.put(os.widen('\n')), then os.flush().

  Returns: os.

template<class charT, class traits>
  basic_ostream<charT, traits>& ends(basic_ostream<charT, traits>& os);

  Effects: Inserts a null character into the output sequence: calls os.put(charT()).

  Returns: os.

template<class charT, class traits>
  basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);

  Effects: Calls os.flush().

  Returns: os.

template<class charT, class traits>
  basic_ostream<charT, traits>& emit_on_flush(basic_ostream<charT, traits>& os);

  Effects: If os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>* called buf for the purpose of exposition, calls buf->set_emit_on_sync(true). Otherwise this manipulator has no effect. [Note: To work around the issue that the Allocator template argument cannot be deduced, implementations can introduce an intermediate base class to basic_syncbuf that manages its emit_on_sync flag. — end note]

  Returns: os.

template<class charT, class traits>
  basic_ostream<charT, traits>& noemit_on_flush(basic_ostream<charT, traits>& os);

  Effects: If os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>* called buf for the purpose of exposition, calls buf->set_emit_on_sync(false). Otherwise this manipulator has no effect.

  Returns: os.

template<class charT, class traits>
  basic_ostream<charT, traits>& flush_emit(basic_ostream<charT, traits>& os);

  Effects: Calls os.flush(). Then, if os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>* called buf for the purpose of exposition, calls buf->emit().

  Returns: os.

29.7.5.5 Rvalue stream insertion

  template<class Ostream, class T>
  Ostream&& operator<<(Ostream&& os, const T& x);

  Constraints: The expression os << x is well-formed when treated as an unevaluated operand and Ostream is publicly and unambiguously derived from ios_base.

  Effects: As if by: os << x;

  Returns: std::move(os).

29.7.6 Standard manipulators

  The header <iomanip> defines several functions that support extractors and inserters that alter information maintained by class ios_base and its derived classes.

  unspecified resetiosflags(ios_base::fmtflags mask);

  Returns: An object of unspecified type such that if out is an object of type basic ostream<charT, traits> then the expression out << resetiosflags(mask) behaves as if it called f(out, mask), or if in is an object of type basic istream<charT, traits> then the expression in >> resetiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as: 322

322 The expression cin >> resetiosflags(ios_base::skipws) clears ios_base::skipws in the format flags stored in the basic_istream<charT, traits> object cin (the same as cin >> noskipws), and the expression cout << resetiosflags(ios_base::showbase) clears ios_base::showbase in the format flags stored in the basic_ostream<charT, traits> object cout (the same as

§ 29.7.6 1373
void f(ios_base& str, ios_base::fmtflags mask) {
    // reset specified flags
    str.setf(ios_base::fmtflags(0), mask);
}

The expression \texttt{out << resetiosflags(mask)} has type \texttt{basic_ostream<charT, traits>}& and value \texttt{out}. The expression \texttt{in >> resetiosflags(mask)} has type \texttt{basic_istream<charT, traits>}& and value \texttt{in}.

4

Returns: An object of unspecified type such that if \texttt{out} is an object of type \texttt{basic_ostream<charT, traits> then the expression \texttt{out << setiosflags(mask)} behaves as if it called \texttt{f(out, mask)}, or if \texttt{in} is an object of type \texttt{basic_istream<charT, traits>} then the expression \texttt{in >> setiosflags(mask)} behaves as if it called \texttt{f(in, mask)}, where the function \texttt{f} is defined as:

```c
void f(ios_base& str, ios_base::fmtflags mask) {
    // set specified flags
    str.setf(mask);
}
```

The expression \texttt{out << setiosflags(mask)} has type \texttt{basic_ostream<charT, traits>}& and value \texttt{out}. The expression \texttt{in >> setiosflags(mask)} has type \texttt{basic_istream<charT, traits>}& and value \texttt{in}.

5

Returns: An object of unspecified type such that if \texttt{out} is an object of type \texttt{basic_ostream<charT, traits> then the expression \texttt{out << setprecision(n)} behaves as if it called \texttt{f(out, n)}, or if \texttt{in} is an object of type \texttt{basic_istream<charT, traits>} then the expression \texttt{in >> setprecision(n)} behaves as if it called \texttt{f(in, n)}, where the function \texttt{f} is defined as:

```c
void f(ios_base& str, int n) {
    // set precision
    str.precision(n);
}
```

The expression \texttt{out << setprecision(n)} has type \texttt{basic_ostream<charT, traits>}& and value \texttt{out}. The expression \texttt{in >> setprecision(n)} has type \texttt{basic_istream<charT, traits>}& and value \texttt{in}.

6

Returns: An object of unspecified type such that if \texttt{out} is an object of type \texttt{basic_ostream<charT, traits> then the expression \texttt{out << setfill(c)} behaves as if it called \texttt{f(out, c)}, where the function \texttt{f} is defined as:

```c
template<class charT, class traits>
void f(basic_ios<charT, traits>& str, charT c) {
    // set fill character
    str.fill(c);
}
```

The expression \texttt{out << setfill(c)} has type \texttt{basic_ostream<charT, traits>}& and value \texttt{out}.

```
unspecified setw(int n);

Returns: An object of unspecified type such that if out is an instance of basic_ostream<charT, traits>
then the expression out << setw(n) behaves as if it called f(out, n), or if in is an object of type basic_-
istream<charT, traits> then the expression in >> setw(n) behaves as if it called f(in, n), where the
function f is defined as:

void f(ios_base& str, int n) {
    // set width
    str.width(n);
}

The expression out << setw(n) has type basic_ostream<charT, traits>& and value out. The expres-
sion in >> setw(n) has type basic_istream<charT, traits>& and value in.

29.7.7 Extended manipulators [ext.manip]

The header <iomanip> defines several functions that support extractors and inserters that allow for the parsing and
formatting of sequences and values for money and time.

template<class moneyT> unspecified get_money(moneyT& mon, bool intl = false);

Mandates: The type moneyT is either long double or a specialization of the basic_string template (Clause
21).

Effects: The expression in >> get_money(mon, intl) described below behaves as a formatted input function
(29.7.4.2.1).

Returns: An object of unspecified type such that if in is an object of type basic_istream<charT, traits>
then the expression in >> get_money(mon, intl) behaves as if it called f(in, mon, intl), where the
function f is defined as:

template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, moneyT& mon, bool intl) {
    using Iter = istreambuf_iterator<charT, traits>;
    using MoneyGet = money_get<charT, Iter>;
    ios_base::iostate err = ios_base::goodbit;
    const MoneyGet& mg = use_facet<MoneyGet>(str.getloc());
    mg.get(Iter(str.rdbuf()), Iter(), intl, str, err, mon);
    if (ios_base::goodbit != err)
        str.setstate(err);
}

The expression in >> get_money(mon, intl) has type basic_istream<charT, traits>& and value in.

template<class moneyT> unspecified put_money(const moneyT& mon, bool intl = false);

Mandates: The type moneyT is either long double or a specialization of the basic_string template (Clause
21).

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits>
then the expression out << put_money(mon, intl) behaves as a formatted output function (29.7.5.2.1) that
calls f(out, mon, intl), where the function f is defined as:

template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, const moneyT& mon, bool intl) {
    using Iter = ostreambuf_iterator<charT, traits>;
    using MoneyPut = money_put<charT, Iter>;
    const MoneyPut& mp = use_facet<MoneyPut>(str.getloc());
    const Iter end = mp.put(Iter(str.rdbuf()), intl, str, str.fill(), mon);
    if (end.failed())
        str.setstate(ios_base::badbit);
}
```
The expression `out << put_money(mon, intl)` has type `basic_ostream<charT, traits>&` and value `out`.

```
template<class charT> unspecified get_time(struct tm* tmb, const charT* fmt);  
```

**Preconditions:** The argument `tmb` is a valid pointer to an object of type `struct tm`, and `[fmt, fmt + char_traits<charT>::length(fmt))` is a valid range.

**Returns:** An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_time(tmb, fmt)` behaves as if it called `f(in, tmb, fmt)`, where the function `f` is defined as:

```
template<class charT, class traits> 
void f(basic_istream<charT, traits>& in, struct tm* tmb, const charT* fmt) {  
  using Iter = istreambuf_iterator<charT, traits>;  
  using TimeGet = time_get<charT, Iter>;  
  ios_base::iostate err = ios_base::goodbit;  
  const TimeGet& tg = use_facet<TimeGet>(in.getloc());  
  tg.get(Iter(in.rdbuf()), Iter(), in, err, tmb, fmt, fmt + traits::length(fmt));  
  if (err != ios_base::goodbit) in.setstate(err);  
}  
```

The expression `in >> get_time(tmb, fmt)` has type `basic_istream<charT, traits>&` and value `in`.

```
template<class charT> unspecified put_time(const struct tm* tmb, const charT* fmt);  
```

**Preconditions:** The argument `tmb` is a valid pointer to an object of type `struct tm`, and `[fmt, fmt + char_traits<charT>::length(fmt))` is a valid range.

**Returns:** An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_time(tmb, fmt)` behaves as if it called `f(out, tmb, fmt)`, where the function `f` is defined as:

```
template<class charT, class traits> 
void f(basic_ostream<charT, traits>& out, const struct tm* tmb, const charT* fmt) {  
  using Iter = ostreambuf_iterator<charT, traits>;  
  using TimePut = time_put<charT, Iter>;  
  const TimePut& tp = use_facet<TimePut>(out.getloc());  
  const Iter end = tp.put(Iter(out.rdbuf()), out, out.fill(), tmb, fmt, fmt + traits::length(fmt));  
  if (end.failed()) out.setstate(ios_base::badbit);  
}  
```

The expression `out << put_time(tmb, fmt)` has type `basic_ostream<charT, traits>&` and value `out`.

### 29.7.8 Quoted manipulators [quoted.manip]

[Note: Quoted manipulators provide string insertion and extraction of quoted strings (for example, XML and CSV formats). Quoted manipulators are useful in ensuring that the content of a string with embedded spaces remains unchanged if inserted and then extracted via stream I/O. — end note]

```
template<class charT>  
unspecified quoted(const charT* s, charT delim = charT('"'), charT escape = charT('\\'));  
template<class charT, class traits, class Allocator>  
unspecified quoted(const basic_string<charT, traits, Allocator>& s, charT delim = charT('"'), charT escape = charT('\\'));  
template<class charT, class traits>  
unspecified quoted(basic_string_view<charT, traits> s,  
```
Returns: An object of unspecified type such that if out is an instance of basic_ostream with member type char_type the same as charT and with member type traits_type, which in the second and third forms is the same as traits, then the expression out << quoted(s, delim, escape) behaves as a formatted output function (29.7.5.2.1) of out. This forms a character sequence seq initially consisting of the following elements:

- delim.
- Each character in s. If the character to be output is equal to escape or delim, as determined by traits_type::eq, first output escape.
- delim.

Let x be the number of elements initially in seq. Then padding is determined for seq as described in 29.7.5.2.1, seq is inserted as if by calling out.rdbuf()->sputn(seq, n), where n is the larger of out.width() and x, and out.width(0) is called. The expression out << quoted(s, delim, escape) has type basic_ostream<charT, traits>& and value out.

template<class charT, class traits, class Allocator>
unspecised quoted(basic_string<charT, traits, Allocator>& s, 
charT delim = charT('"'), charT escape = charT('\\'));

Returns: An object of unspecified type such that:

- If in is an instance of basic_istream with member types char_type and traits_type the same as charT and traits, respectively, then the expression in >> quoted(s, delim, escape) behaves as if it extracts the following characters from in using operator>>(basic_istream<charT, traits>&, 
charT) (29.7.4.2.3) which may throw ios_base::failure (29.5.3.1.1):
  - If the first character extracted is equal to delim, as determined by traits_type::eq, then:
    - Turn off the skipws flag.
    - s.clear()
    - Until an unescaped delim character is reached or !in, extract characters from in and append them to s, except that if an escape is reached, ignore it and append the next character to s.
    - Discard the final delim character.
    - Restore the skipws flag to its original value.
  - Otherwise, in >> s.
- If out is an instance of basic_ostream with member types char_type and traits_type the same as charT and traits, respectively, then the expression out << quoted(s, delim, escape) behaves as specified for the const basic_string<charT, traits, Allocator>& overload of the quoted function.
- The expression in >> quoted(s, delim, escape) has type basic_istream<charT, traits>& and value in.
- The expression out << quoted(s, delim, escape) has type basic_ostream<charT, traits>& and value out.

29.8 String-based streams [string.streams]

29.8.1 Header <sstream> synopsis [sstream.syn]

namespace std {
  template<class charT, class traits = char_traits<charT>, 
  class Allocator = allocator<charT>>
  class basic_stringbuf;

  using stringbuf = basic_stringbuf<char>;
  using wstringbuf = basic_stringbuf<wchar_t>;

  template<class charT, class traits = char_traits<charT>, 
  class Allocator = allocator<charT>>
  class basic_istringstream;

§ 29.8.1
using istringstream = basic_istringstream<char>;
using wistringstream = basic_istringstream<wchar_t>;

template<class charT, class traits = char_traits<charT>,
          class Allocator = allocator<charT>>
class basic_ostringstream;
using ostringstream = basic_ostringstream<char>;
using wostringstream = basic_ostringstream<wchar_t>;

template<class charT, class traits = char_traits<charT>,
          class Allocator = allocator<charT>>
class basic_stringstream;
using stringstream = basic_stringstream<char>;
using wstringstream = basic_stringstream<wchar_t>;

} // namespace std

The header `<sstream>` defines four class templates and eight types that associate stream buffers with objects of class `basic_string`, as described in 21.3.

### 29.8.2 Class template `basic_stringbuf` [stringbuf]

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_stringbuf : public basic_streambuf<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

        // 29.8.2.1, constructors
        basic_stringbuf() : basic_stringbuf(ios_base::in | ios_base::out) {};
        explicit basic_stringbuf(ios_base::openmode which);
        explicit basic_stringbuf(const basic_string<charT, traits, Allocator>& s,
                                  ios_base::openmode which = ios_base::in | ios_base::out);
        explicit basic_stringbuf(const Allocator& a)

private:
ios_base::openmode mode; // exposition only
basic_string<
charT,
traits,
Allocator> buf; // exposition only
void init_buf_ptrs(); // exposition only
};

template<class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>& x,
  basic_stringbuf<charT, traits, Allocator>& y) noexcept(noexcept(x.swap(y)));

1 The class basic_stringbuf is derived from basic_streambuf to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary characters. The sequence can be initialized from, or made available as, an object of class basic_string.

2 For the sake of exposition, the maintained data and internal pointer initialization is presented here as:

(2.1) — ios_base::openmode mode, has in set if the input sequence can be read, and out set if the output sequence can be written.

(2.2) — basic_string<
charT,
traits,
Allocator>
buf contains the underlying character sequence.

(2.3) — init_buf_ptrs() sets the base class’ get area (29.6.3.3.2) and put area (29.6.3.3.3) pointers after initializing, moving from, or assigning to buf accordingly.

29.8.2.1 Constructors [stringbuf.cons]
explicit basic_stringbuf(ios_base::openmode which);

1 Effects: Initializes the base class with basic_streambuf() (29.6.3.1), and mode with which. It is implementation-defined whether the sequence pointers (eback(), gptr(), egptr(), pbase(), pptr(), epptr()) are initialized to null pointers.

2 Postconditions: str().empty() is true.
ios_base::openmode which = ios_base::in | ios_base::out);

Effects: Initializes the base class with basic_streambuf() (29.6.3.1), mode with which, and buf with s, then calls init_buf_ptrs().

basic_stringbuf(ios_base::openmode which, const Allocator &a);

Effects: Initializes the base class with basic_streambuf() (29.6.3.1), mode with which, and buf with a, then calls init_buf_ptrs().

Postconditions: str().empty() is true.

explicit basic_stringbuf(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::in | ios_base::out);

Effects: Initializes the base class with basic_streambuf() (29.6.3.1), mode with which, and buf with std::move(s), then calls init_buf_ptrs().

template<class SAlloc>
basic_stringbuf(
    const basic_string<charT, traits, SAlloc>&& s,
    ios_base::openmode which = ios_base::in | ios_base::out);

Effects: Initializes the base class with basic_streambuf() (29.6.3.1), mode with which, and buf with {s, a}, then calls init_buf_ptrs().

template<class SAlloc>
explicit basic_stringbuf(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which = ios_base::in | ios_base::out);

Constraints: is_same_v<SAlloc, Allocator> is false.

Effects: Initializes the base class with basic_streambuf() (29.6.3.1), mode with which, and buf with s, then calls init_buf_ptrs().

basic_stringbuf(basic_stringbuf&& rhs);

Effects: Copy constructs the base class from rhs and initializes mode with rhs.mode. In the first form buf is initialized from std::move(rhs).str(). In the second form buf is initialized from {std::move(rhs).str(), a}. It is implementation-defined whether the sequence pointers in *this (eback(), gptr(), egptr(), pbase(), pptr(), epptr()) obtain the values which rhs had.

Postconditions: Let rhs_p refer to the state of rhs just prior to this construction and let rhs_a refer to the state of rhs just after this construction.

- str() == rhs_p.str()
- gptr() - eback() == rhs_p.gptr() - rhs_p.eback()
- egptr() - eback() == rhs_p.egptr() - rhs_p.eback()
- pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()
- eptr() - pbase() == rhs_p.eptr() - rhs_p.pbase()
- if (eback()) eback() != rhs_a.eback()
- if (gptr()) gptr() != rhs_a.gptr()
- if (egptr()) egptr() != rhs_a.egptr()
- if (pptr()) pbase() != rhs_a.pbase()
- if (pptr()) pptr() != rhs_a.pptr()
- if (eptr()) eptr() != rhs_a.eptr()
- getloc() == rhs_p.getloc()
- rhs is empty but usable, as if std::move(rhs).str() was called.
29.8.2.2 Assignment and swap

basic_stringbuf& operator=(basic_stringbuf&& rhs);

Effects: After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (see 29.8.2.1).

Returns: *this.

void swap(basic_stringbuf& rhs) noexcept (see below);

Preconditions: allocator_traits<Allocator>::propagate_on_container_swap::value is true or get_-

allocator() == s.get_allocator() is true.

Effects: Exchanges the state of *this and rhs.

Remarks: The expression inside noexcept is equivalent to:

allocator_traits<Allocator>::propagate_on_container_swap::value ||

allocator_traits<Allocator>::is_always_equal::value.

template<class charT, class traits, class Allocator>

void swap(basic_stringbuf<charT, traits, Allocator>& x, 
basic_stringbuf<charT, traits, Allocator>& y) noexcept(noexcept(x.swap(y)));

Effects: Equivalent to: x.swap(y).

29.8.2.3 Member functions

The member functions getting the underlying character sequence all refer to a high_mark value, where high_mark represents the position one past the highest initialized character in the buffer. Characters can be initialized by writing to the stream, by constructing the basic_stringbuf passing a basic_string argument, or by calling one of the str member functions passing a basic_string as an argument. In the latter case, all characters initialized prior to the call are now considered uninitialized (except for those characters re-initialized by the new basic_string).

void init_buf_ptrs(); // exposition only

Effects: Initializes the input and output sequences from buf according to mode.

Postconditions:

(3.1) — If ios_base::out is set in mode, pbase() points to buf.front() and epptr() >= pbase() + buf.size() is true;

(3.1) — in addition, if ios_base::ate is set in mode, pptr() == pbase() + buf.size() is true,

(3.2) — otherwise pptr() == pbase() is true.

(3.2) — If ios_base::in is set in mode, eback() points to buf.front(), and (gptr() == eback() &&

egrep() == eback() + buf.size()) is true.

[Note: For efficiency reasons, stream buffer operations might violate invariants of buf while it is held encapsulated in the basic_stringbuf, e.g., by writing to characters in the range [buf.data() + buf.size(),

data() + buf.capacity()]. All operations retrieving a basic_string from buf ensure that the basic_string invariants hold on the returned value. — end note]

allocator_type get_allocator() const noexcept;

Returns: buf.get_allocator().

basic_string<charT, traits, Allocator> str() const &;

Effects: Equivalent to:

return basic_string<charT, traits, Allocator>(view(), get_allocator());

template<class SAlloc>

basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;

Constraints: SAlloc is a type that qualifies as an allocator (22.2.1).

Effects: Equivalent to:

return basic_string<charT, traits, SAlloc>(view(), sa);
basic_string<charT, traits, Allocator> str() &&;

**Postconditions:** The underlying character sequence `buf` is empty and pbase(), pptr(), epptr(), eback(),
gptr(), and egptr() are initialized as if by calling init_buf_ptrs() with an empty `buf`.

**Returns:** A `basic_string<charT, traits, Allocator>` object move constructed from the `basic_stringbuf`'s underlying character sequence in `buf`. This can be achieved by first adjusting `buf` to have the same content as `view()`.

basic_string_view<charT, traits> view() const noexcept;

Let `sv` be `basic_string_view<charT, traits>`.

**Returns:** A `sv` object referring to the `basic_stringbuf`'s underlying character sequence in `buf`:

1. If `ios_base::out` is set in `mode`, then `sv(pbase(), high_mark-pbase())` is returned.
2. Otherwise, if `ios_base::in` is set in `mode`, then `sv(eback(), egptr()-eback())` is returned.
3. Otherwise, `sv()` is returned.

[Note: Using the returned `sv` object after destruction or invalidation of the character sequence underlying `*this` is undefined behavior, unless `sv.empty()` is true. — end note]

void str(const basic_string<charT, traits, Allocator>& s);

**Effects:** Equivalent to:

```
buf = s;
init_buf_ptrs();
```

**Template:**

```template<class SAlloc>
void str(const basic_string<charT, traits, SAlloc>& s);
```

**Constraints:** `is_same_v<SAlloc,Allocator> is false`.

**Effects:** Equivalent to:

```
buf = s;
init_buf_ptrs();
```

void str(basic_string<charT, traits, Allocator>&& s);

**Effects:** Equivalent to:

```
buf = std::move(s);
init_buf_ptrs();
```

### 29.8.2.4 Overridden virtual functions

```int_type underflow() override;
```

**Returns:** If the input sequence has a read position available, returns `traits::to_int_type(*gptr())`. Otherwise, returns `traits::eof()`. Any character in the underlying buffer which has been initialized is considered to be part of the input sequence.

```int_type pbackfail(int_type c = traits::eof()) override;
```

**Effects:** Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

1. If `traits::eq_int_type(c, traits::eof())` returns `false` and if the input sequence has a putback position available, and if `traits::eq(to_char_type(c), gptr()[-1])` returns `true`, assigns `gptr()` `- 1` to `gptr()`.

   Returns: `c`.

2. If `traits::eq_int_type(c, traits::eof())` returns `false` and if the input sequence has a putback position available, and if `mode & ios_base::out` is nonzero, assigns `c` to `*--gptr()`.

   Returns: `c`.

3. If `traits::eq_int_type(c, traits::eof())` returns `true` and if the input sequence has a putback position available, assigns `gptr()` `- 1` to `gptr()`.

   Returns: `traits::not_eof(c)`.

§ 29.8.2.4
Returns: As specified above, or traits::eof() to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen.

```cpp
int_type overflow(int_type c = traits::eof()) override;
```

Effects: Appends the character designated by `c` to the output sequence, if possible, in one of two ways:

- If traits::eq_int_type(c, traits::eof()) returns false and if either the output sequence has a write position available or the function makes a write position available (as described below), the function calls sputc(c).
  Signals success by returning `c`.

- If traits::eq_int_type(c, traits::eof()) returns true, there is no character to append.
  Signals success by returning a value other than traits::eof().

Returns: As specified above, or traits::eof() to indicate failure.

Remarks: The function can alter the number of write positions available as a result of any call.

The function can make a write position available only if ios_base::out is set in mode. To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements to hold the current array object (if any), plus at least one additional write position. If ios_base::in is set in mode, the function alters the read end pointer egptr() to point just past the new write position.

```cpp
pos_type seekoff(off_type off, ios_base::seekdir way, ios_base::openmode which = ios_base::in | ios_base::out) override;
```

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 124.

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>ios_base::in is set in which</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>ios_base::out is set in which</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>both ios_base::in and ios_base::out are set in which and either way == ios_base::beg or way == ios_base::end</td>
<td>positions both the input and the output sequences</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, the function determines `newoff` as indicated in Table 125. If the sequence’s next pointer (either gptr() or pptr()) is a null pointer and `newoff` is nonzero, the positioning operation fails.

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios_base::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios_base::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios_base::end</td>
<td>the high mark pointer minus the beginning pointer (high_mark - xbeg).</td>
</tr>
</tbody>
</table>

If (newoff + off) < 0, or if newoff + off refers to an uninitialized character (29.8.2.3), the positioning operation fails. Otherwise, the function assigns xbeg + newoff + off to the next pointer xnext.

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).
pos_type seekpos(pos_type sp,
   ios_base::openmode which
   = ios_base::in | ios_base::out) override;

Effects: Equivalent to seekoff(off_type(sp), ios_base::beg, which).

Returns: sp to indicate success, or pos_type(off_type(-1)) to indicate failure.

basic_streambuf<charT, traits*>* setbuf(charT* s, streamsize n);

Effects: implementation-defined, except that setbuf(0, 0) has no effect.

Returns: this.

29.8.3 Class template basic_istringstream

namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_istringstream : public basic_istream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

            // 29.8.3.1. constructors
            basic_istringstream() : basic_istringstream(ios_base::in) {} 
            explicit basic_istringstream(ios_base::openmode which);
            explicit basic_istringstream( 
                const basic_string<charT, traits, Allocator>& s,
                ios_base::openmode which = ios_base::in);
            basic_istringstream(ios_base::openmode which, const Allocator& a);
            explicit basic_istringstream( 
                basic_string<charT, traits, Allocator>&& s,
                ios_base::openmode which = ios_base::in);
            template<class SAlloc>

            template<class SAlloc>
            basic_string<charT,traits,SAlloc> str(const SAlloc& sa) const;
            basic_string<charT, traits, Allocator> str() &;
            basic_string_view<charT, traits> view() const noexcept;

§ 29.8.3 1384
void str(const basic_string<charT, traits, Allocator>& s);
void str(const basic_string<charT, traits, SAlloc>& s);
void str(basic_string<charT, traits, Allocator>&& s);

private:
    basic_stringbuf<charT, traits, Allocator> sb; // exposition only
};

template<class charT, class traits, class Allocator>
void swap(basic_istringstream<charT, traits, Allocator>& x,
          basic_istringstream<charT, traits, Allocator>& y);

The class basic_istringstream<charT, traits, Allocator> supports reading objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf<charT, traits, Allocator> object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

— sb, the stringbuf object.

29.8.3.1 Constructors

explicit basic_istringstream(ios_base::openmode which);

1 Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1) and sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::in) (29.8.2.1).

explicit basic_istringstream(
    const basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::in);

2 Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1) and sb with basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::in) (29.8.2.1).

basic_istringstream(ios_base::openmode which, const Allocator& a);

3 Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1) and sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::in, a) (29.8.2.1).

explicit basic_istringstream(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::in);

4 Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1) and sb with basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::in) (29.8.2.1).

template<class SAlloc>
basic_istringstream(
    const basic_string<charT, traits, SAlloc>& s,
    SAlloc& a);

5 Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1) and sb with basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::in, a) (29.8.2.1).

template<class SAlloc>
explicit basic_istringstream(
    const basic_string<charT, traits, SAlloc>&& s,
    SAlloc& a);

6 Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1) and sb with basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::in) (29.8.2.1).

basic_istringstream(basic_istringstream&& rhs);

7 Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_stringbuf. Then calls basic_istream<charT, traits>::set_rdbuf(addressof(sb)) to install the contained basic_stringbuf.
29.8.3.2 Assignment and swap

void swap(basic_istringstream& rhs);

Effects: Equivalent to:

basic_istream<charT, traits>::swap(rhs);

sb.swap(rhs.sb);

template<class charT, class traits, class Allocator>
void swap(basic_istringstream<charT, traits, Allocator>& x,
basic_istringstream<charT, traits, Allocator>& y);

Effects: Equivalent to: x.swap(y).

29.8.3.3 Member functions

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

Returns: const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb)).

basic_string<charT, traits, Allocator> str() const &;

Effects: Equivalent to: return rdbuf()->str();

template<class SAlloc>
basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;

Effects: Equivalent to: return rdbuf()->str(sa);

basic_string_view<charT, traits> view() const noexcept;

Effects: Equivalent to: return rdbuf()->view();

void str(const basic_string<charT, traits, Allocator>& s);

Effects: Equivalent to: rdbuf()->str(s);

template<class SAlloc>
void str(const basic_string<charT, traits, SAlloc>& s);

Effects: Equivalent to: rdbuf()->str(s);

void str(basic_string<charT, traits, Allocator>&& s);

Effects: Equivalent to: rdbuf()->str(std::move(s));

29.8.4 Class template basic_ostringstream

namespace std {

template<class charT, class traits = char_traits<charT>,
class Allocator = allocator<charT>>
class basic_ostringstream : public basic_ostream<charT, traits> {

public:

using char_type = charT;
using int_type = typename traits::int_type;

    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which, const Allocator& a);

template<class SAlloc>
explicit basic_ostringstream(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which = ios_base::out);

basic_ostringstream(const basic_ostringstream& rhs) = delete;

basic_ostringstream(basic_ostringstream&& rhs);

// 29.8.4.2, assign and swap
basic_ostringstream& operator=(const basic_ostringstream& rhs) = delete;

basic_ostringstream& operator=(basic_ostringstream&& rhs);

void swap(basic_ostringstream& rhs);

// 29.8.4.3, members

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

basic_string<charT, traits, Allocator> str() const &;

template<class SAlloc>
    basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;

basic_string<charT, traits, Allocator> str() &&;

basic_string_view<charT, traits> view() const noexcept;

void str(const basic_string<charT, traits, Allocator>& s);

template<class SAlloc>
void str(const basic_string<charT, traits, SAlloc>& s);

void str(basic_string<charT, traits, Allocator>&& s);

private:
    basic_stringbuf<charT, traits, Allocator> sb;   // exposition only
);

template<class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
    basic_ostringstream<charT, traits, Allocator>&& y);

The class basic_ostringstream<charT, traits, Allocator> supports writing objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

sb, the stringbuf object.

29.8.4.1 Constructors

explicit basic_ostringstream(ios_base::openmode which);

Effects: Initializes the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1) and sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::out) (29.8.2.1).

explicit basic_ostringstream(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::out);

Effects: Initializes the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1) and sb with basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::out) (29.8.2.1).
basic_ostringstream(ios_base::openmode which, const Allocator& a);

Effects: Initializes the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1) and sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::out, a) (29.8.2.1).

explicit basic_ostringstream(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::out);

Effects: Initializes the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1) and sb with basic_stringbuf<charT, traits, Allocator>(std::move(s), which | ios_base::out) (29.8.2.1).

template<class SAlloc>

basic_ostringstream(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which, const Allocator& a);

Effects: Initializes the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1) and sb with basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::out, a) (29.8.2.1).

template<class SAlloc>

explicit basic_ostringstream(
    const basic_string<charT, traits, SAlloc>& s,
    ios_base::openmode which = ios_base::out); Constraints: is_same_v<SAlloc, Allocator> is false.

Effects: Initializes the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1) and sb with basic_stringbuf<charT, traits, Allocator>(s, which | ios_base::out) (29.8.2.1).

basic_ostringstream(basic_ostringstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_stringbuf. Then calls basic_ostream<charT, traits>::set_rdbuf(addressof(sb)) to install the contained basic_stringbuf.

29.8.4.2 Assignment and swap [ostringstream.assign]

void swap(basic_ostringstream& rhs);

Effects: Equivalent to:
    basic_ostream<charT, traits>::swap(rhs);
    sb.swap(rhs.sb);

template<class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
    basic_ostringstream<charT, traits, Allocator>& y);

Effects: Equivalent to: x.swap(y).

29.8.4.3 Member functions [ostringstream.members]

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

Returns: const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb)).

basic_string<charT, traits, Allocator> str() const &;

Effects: Equivalent to: return rdbuf()->str();

template<class SAlloc>

basic_string<charT, traits, SAlloc> str(const SAlloc& sa) const;

Effects: Equivalent to: return rdbuf()->str(sa);
basic_string<charT,traits,Allocator> str() &&;

Effects: Equivalent to: return std::move(*rdbuf()).str();

basic_string_view<charT, traits> view() const noexcept;

Effects: Equivalent to: return rdbuf()->view();

void str(const basic_string<charT, traits, Allocator>& s);

Effects: Equivalent to: rdbuf()->str(s);

template<class SAlloc>
void str(const basic_string<charT, traits, SAlloc>& s);

Effects: Equivalent to: rdbuf()->str(s);

void str(basic_string<charT, traits, Allocator>&& s);

Effects: Equivalent to: rdbuf()->str(std::move(s));

29.8.5 Class template basic_stringstream

namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_stringstream : public basic_iostream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

            // 29.8.5.1, constructors
            basic_stringstream() : basic_stringstream(ios_base::out | ios_base::in) {}{
        explicit basic_stringstream(ios_base::openmode which);
        explicit basic_stringstream(
            const basic_string<charT, traits, Allocator>& s,
            ios_base::openmode which = ios_base::out | ios_base::in);
        basic_stringstream(ios_base::openmode which, const Allocator& a);
        explicit basic_stringstream(
            basic_string<charT, traits, Allocator>&& s,
            ios_base::openmode which = ios_base::out | ios_base::in);
        template<class SAlloc>
        basic_stringstream(
            const basic_string<charT, traits, SAlloc>& s, const Allocator& a)
            : basic_stringstream(s, ios_base::out | ios_base::in, a) {}{
        template<class SAlloc>
        basic_stringstream(
            const basic_string<charT, traits, SAlloc>& s,
            ios_base::openmode which, const Allocator& a);
        template<class SAlloc>
        explicit basic_stringstream(
            const basic_string<charT, traits, SAlloc>& s,
            ios_base::openmode which = ios_base::out | ios_base::in);
        basic_stringstream(const basic_stringstream&) = delete;
        basic_stringstream(basic_stringstream&& rhs);

            // 29.8.5.2, assign and swap
            basic_stringstream& operator=(const basic_stringstream&) = delete;
            basic_stringstream& operator=(basic_stringstream&& rhs);
            void swap(basic_stringstream& rhs);

            // 29.8.5.3, members
            basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as

(1.1) \( \text{sb, the stringbuf object.} \)

### 29.8.5.1 Constructors

[stringstream.cons]

```cpp
explicit basic_stringstream(ios_base::openmode which);
```

1. **Effects:** Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` and \( \text{sb with basic_stringbuf<charT, traits, Allocator>(which).} \)

```cpp
explicit basic_stringstream(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::out | ios_base::in);
```

2. **Effects:** Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` and \( \text{sb with basic_stringbuf<charT, traits, Allocator>(s, which).} \)

```cpp
basic_stringstream(ios_base::openmode which, const Allocator& a);
```

3. **Effects:** Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` and \( \text{sb with basic_stringbuf<charT, traits, Allocator>(which, a).} \)

```cpp
explicit basic_stringstream(
    basic_string<charT, traits, Allocator>&& s,
    ios_base::openmode which = ios_base::out | ios_base::in);
```

4. **Effects:** Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` and \( \text{sb with basic_stringbuf<charT, traits, Allocator>(std::move(s), which).} \)

```cpp
template<class SAlloc>
    basic_stringstream(
        const basic_string<charT, traits, SAlloc>& s,
        ios_base::openmode which = ios_base::out | ios_base::in);
```

5. **Effects:** Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` and \( \text{sb with basic_stringbuf<charT, traits, Allocator>(s, which, a).} \)

```cpp
template<class SAlloc>
    explicit basic_stringstream(
        const basic_string<charT, traits, SAlloc>& s,
        ios_base::openmode which = ios_base::out | ios_base::in);
```

6. **Constraints:** `is_same_v<SAlloc, Allocator>` is false.

7. **Effects:** Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` and \( \text{sb with basic_stringbuf<charT, traits, Allocator>(s, which).} \)
basic_stringstream(basic_stringstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_stringbuf. Then calls basic_istream<charT, traits>::set_rdbuf(addressof(sb)) to install the contained basic_stringbuf.

29.8.5.2 Assignment and swap  

void swap(basic_stringstream& rhs);

Effects: Equivalent to:

basic_iostream<charT,traits>::swap(rhs);
sb.swap(rhs.sb);

template<class charT, class traits, class Allocator>
void swap(basic_stringstream<charT, traits, Allocator>& x,
basic_stringstream<charT, traits, Allocator>& y);

Effects: Equivalent to: x.swap(y).

29.8.5.3 Member functions  

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

Returns: const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb)).

basic_string<charT, traits, Allocator> str() const &;

Effects: Equivalent to: return rdbuf()->str();

template<class SAlloc>
basic_string<charT,traits,SAlloc> str(const SAlloc& sa) const;

Effects: Equivalent to: return rdbuf()->str(sa);

basic_string_view<charT, traits> view() const noexcept;

Effects: Equivalent to: return rdbuf()->view();

void str(const basic_string<charT, traits, Allocator>& s);

Effects: Equivalent to: rdbuf()->str(s);

template<class SAlloc>
void str(const basic_string<charT, traits, SAlloc>& s);

Effects: Equivalent to: rdbuf()->str(s);

void str(basic_string<charT, traits, Allocator>&& s);

Effects: Equivalent to: rdbuf()->str(std::move(s));

29.9 File-based streams

29.9.1 Header <fstream> synopsis

namespace std {
  template<class charT, class traits = char_traits<charT>>
  class basic_filebuf;
  using filebuf = basic_filebuf<char>;
  using wfilebuf = basic_filebuf<wchar_t>;
  
  template<class charT, class traits = char_traits<charT>>
  class basic_ifstream;
  using ifstream = basic_ifstream<char>;
  using wifstream = basic_ifstream<wchar_t>;
}
The header `<fstream>` defines four class templates and eight types that associate stream buffers with files and assist reading and writing files.

[Note: The class template `basic_filebuf` treats a file as a source or sink of bytes. In an environment that uses a large character set, the file typically holds multibyte character sequences and the `basic_filebuf` object converts those multibyte sequences into wide character sequences. — end note]

In subclause 29.9, member functions taking arguments of `const filesystem::path::value_type*` are only be provided on systems where `filesystem::path::value_type` (29.11.7) is not `char`. [Note: These functions enable class path support for systems with a wide native path character type, such as `wchar_t`. — end note]

### 29.9.2 Class template basic_filebuf

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_filebuf : public basic_streambuf<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

            basic_filebuf();
            basic_filebuf(const basic_filebuf&) = delete;
            basic_filebuf(basic_filebuf&& rhs);
            virtual ~basic_filebuf();

            basic_filebuf* open(const char* s, ios_base::openmode mode);
            basic_filebuf* open(const filesystem::path::value_type* s,
                                 ios_base::openmode mode); // wide systems only; see 29.9.1
            basic_filebuf* open(const string& s,
                                 ios_base::openmode mode);
            basic_filebuf* open(const filesystem::path& s,
                                 ios_base::openmode mode);
            basic_filebuf* close();

        protected:
            streamsize showmanyc() override;
            int_type underflow() override;
            int_type uflow() override;
            int_type pbackfail(int_type c = traits::eof()) override;
            int_type overflow (int_type c = traits::eof()) override;

            basic_streambuf<charT, traits>* setbuf(char_type* s,
                       streamsize n) override;
    }
}
```
The class `basic_filebuf` associates both the input sequence and the output sequence with a file.

The restrictions on reading and writing a sequence controlled by an object of class `basic_filebuf` are the same as for reading and writing with the C standard library `FILE`s.

In particular:

1. If the file is not open for reading the input sequence cannot be read.
2. If the file is not open for writing the output sequence cannot be written.
3. A joint file position is maintained for both the input sequence and the output sequence.

An instance of `basic_filebuf` behaves as described in §29.9.2 provided `traits::pos_type` is `fpos<traits::state_type>`. Otherwise the behavior is undefined.

In order to support file I/O and multibyte/wide character conversion, conversions are performed using members of a facet, referred to as `a_codecvt` in following subclauses, obtained as if by

```cpp
const codecvt<charT, char, typename traits::state_type>& a_codecvt = use_facet<codecvt<charT, char, typename traits::state_type>>(getloc());
```

### 29.9.2.1 Constructors

`basic_filebuf();`

*Effects*: Initializes the base class with `basic_streambuf<charT, traits>()` (29.6.3.1).

*Postconditions*: `is_open() == false`.

`basic_filebuf(basic_filebuf& rhs);`

*Effects*: It is implementation-defined whether the sequence pointers in `*this` (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) obtain the values which `rhs` had. Whether they do or not, `*this` and `rhs` reference separate buffers (if any at all) after the construction. Additionally `*this` references the file which `rhs` did before the construction, and `rhs` references no file after the construction. The openmode, locale and any other state of `rhs` is also copied.

*Postconditions*: Let `rhs_p` refer to the state of `rhs` just prior to this construction and let `rhs_a` refer to the state of `rhs` just after this construction.

```cpp
  - is_open() == rhs_p.is_open()
  - rhs_a.is_open() == false
  - gptr() - eback() == rhs_p.gptr() - rhs_p.eback()
  - egptr() - eback() == rhs_p.egptr() - rhs_p.eback()
  - pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()
  - epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()
  - if (eback()) eback() != rhs_a.eback()
  - if (gptr()) gptr() != rhs_a.gptr()
  - if (egptr()) egptr() != rhs_a.egptr()
  - if (pbase()) pbase() != rhs_a.pbase()
```
virtual ~basic_filebuf();

Effects: Calls close(). If an exception occurs during the destruction of the object, including the call to close(), the exception is caught but not rethrown (see 16.5.5.13).

29.9.2.2 Assignment and swap

basic_filebuf& operator=(basic_filebuf&& rhs);

Effects: Calls close() then move assigns from rhs. After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (see 29.9.2.1).

Returns: *this.

void swap(basic_filebuf& rhs);

Effects: Exchanges the state of *this and rhs.

template<class charT, class traits>
void swap(basic_filebuf<charT, traits>& x, basic_filebuf<charT, traits>& y);

Effects: Equivalent to: x.swap(y).

29.9.2.3 Member functions

bool is_open() const;

Returns: true if a previous call to open succeeded (returned a non-null value) and there has been no intervening call to close.

basic_filebuf* open(const char* s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path::value_type* s, ios_base::openmode mode); // wide systems only; see 29.9.1

Preconditions: s points to a NTCTS (16.3.18).

Effects: If is_open() != false, returns a null pointer. Otherwise, initializes the filebuf as required. It then opens the file to which s resolves, if possible, as if by a call to fopen with the second argument determined from mode & ~ios_base::ate as indicated in Table 126. If mode is not some combination of flags shown in the table then the open fails.

If the open operation succeeds and ios_base::ate is set in mode, positions the file to the end (as if by calling fseek(file, 0, SEEK_END), where file is the pointer returned by calling fopen).323

If the repositioning operation fails, calls close() and returns a null pointer to indicate failure.

Returns: this if successful, a null pointer otherwise.

basic_filebuf* open(const string& s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path& s, ios_base::openmode mode);

Returns: open(s.c_str(), mode);

basic_filebuf* close();

Effects: If is_open() == false, returns a null pointer. If a put area exists, calls overflow(traits::eof()) to flush characters. If the last virtual member function called on *this (between underflow, overflow, seekoff, and seekpos) was overflow then calls a_codecvt.unshift (possibly several times) to determine a termination sequence, inserts those characters and calls overflow(traits::eof()) again. Finally, regardless of whether any of the preceding calls fails or throws an exception, the function closes the file (as if by calling fclose(file)). If any of the calls made by the function, including fclose, fails, close fails by returning a null pointer. If one of these calls throws an exception, the exception is caught and rethrown after closing the file.

Postconditions: is_open() == false.

323) The macro SEEK_END is defined, and the function signatures fopen(const char*, const char*) and fseek(FILE*, long, int) are declared, in <stdio.h> (29.12.1).
Table 126: File open modes

</tr>
<tr>
<td>+</td>
<td>&quot;a+b&quot;</td>
</tr>
</tbody>
</table>

Returns: this on success, a null pointer otherwise.

29.9.2.4 Overridden virtual functions

```cpp
streamsize showmanyc() override;
```

Effects: Behaves the same as basic_streambuf::showmanyc() (29.6.3.4).

Remarks: An implementation might well provide an overriding definition for this function signature if it can determine that more characters can be read from the input sequence.

```cpp
int_type underflow() override;
```

Effects: Behaves according to the description of basic_streambuf<charT, traits>::underflow(), with the specialization that a sequence of characters is read from the input sequence as if by reading from the associated file into an internal buffer (extern_buf) and then as if by doing:

```cpp
codecvt_base::result r =
a_codecvt.in(state, extern_buf, extern_buf+XSIZE, extern_end,
intern_buf, intern_buf+ISIZE, intern_end);
```

This shall be done in such a way that the class can recover the position (fpos_t) corresponding to each character between intern_buf and intern_end. If the value of r indicates that a_codecvt.in() ran out of space in intern_buf, retry with a larger intern_buf.

```cpp
int_type uflow() override;
```

Effects: Behaves according to the description of basic_streambuf<charT, traits>::uflow(), with the specialization that a sequence of characters is read from the input with the same method as used by underflow.

```cpp
int_type pbackfail(int_type c = traits::eof()) override;
```

Effects: Puts back the character designated by c to the input sequence, if possible, in one of three ways:

- If traits::eq_int_type(c, traits::eof()) returns false and if the function makes a putback position available and if traits::eq(to_char_type(c), gptr()[-1]) returns true, decrements the next pointer for the input sequence, gptr().
Returns: c.

— If `traits::eq_int_type(c, traits::eof())` returns `false` and if the function makes a putback position available and if the function is permitted to assign to the putback position, decrements the next pointer for the input sequence, and stores c there.

Returns: c.

— If `traits::eq_int_type(c, traits::eof())` returns `true`, and if either the input sequence has a putback position available or the function makes a putback position available, decrements the next pointer for the input sequence, `gptr()`.

Returns: `traits::not_eof(c)`.

6 Returns: As specified above, or `traits::eof()` to indicate failure.

Remarks: If `is_open() == false`, the function always fails.

The function does not put back a character directly to the input sequence.

9 If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

```cpp
int_type overflow(int_type c = traits::eof()) override;
```

Effects: Behaves according to the description of `basic_streambuf<charT, traits>::overflow(c)`, except that the behavior of "consuming characters" is performed by first converting as if by:

```cpp
charT* b = pbase();
charT* p = pptr();
charT* end;
char xbuf[XSIZE];
char* xbuf_end;
```

```cpp
codecvt_base::result r =
a_codecvt.out(state, b, p, end, xbuf, xbuf+XSIZE, xbuf_end);
```

and then

10

— If `r == codecvt_base::error` then fail.

— If `r == codecvt_base::noconv` then output characters from b up to (and not including) p.

— If `r == codecvt_base::partial` then output to the file characters from xbuf up to xbuf_end, and repeat using characters from end to p. If output fails, fail (without repeating).

— Otherwise output from xbuf to xbuf_end, and fail if output fails. At this point if b != p and b == end (xbuf isn’t large enough) then increase XSIZE and repeat from the beginning.

11 Returns: `traits::not_eof(c)` to indicate success, and `traits::eof()` to indicate failure. If `is_open() == false`, the function always fails.

```cpp
basic_streambuf* setbuf(char_type* s, streamsize n) override;
```

Effects: If `setbuf(0, 0)` is called on a stream before any I/O has occurred on that stream, the stream becomes unbuffered. Otherwise the results are implementation-defined. "Unbuffered" means that `pbase()` and `pptr()` always return null and output to the file should appear as soon as possible.

```cpp
pos_type seekoff(off_type off, ios_base::seekdir way,
    ios_base::openmode which
    = ios_base::in | ios_base::out) override;
```

Effects: Let `width` denote `a_codecvt.encoding()`. If `is_open() == false`, or `off != 0 && width <= 0`, then the positioning operation fails. Otherwise, if `way != basic_ios::cur` or `off != 0`, and if the last operation was output, then update the output sequence and write any unshift sequence. Next, seek to the new position: if `width > 0`, call `fseek(file, width * off, whence)`. otherwise call `fseek(file, 0, whence)`.

13 Returns: A newly constructed `pos_type` object that stores the resultant stream position, if possible. If the positioning operation fails, or if the object cannot represent the resultant stream position, returns `pos_type(off_type(-1))`.

Remarks: “The last operation was output” means either the last virtual operation was overflow or the put buffer is non-empty. “Write any unshift sequence” means, if `width` if less than zero then call a-
codecvt.unshift(state, xbuf, xbuf+XSIZE, xbuf_end) and output the resulting unshift sequence. The function determines one of three values for the argument whence, of type int, as indicated in Table 127.

### Table 127: seekoff effects

<table>
<thead>
<tr>
<th>way</th>
<th>Value</th>
<th>stdio Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basic_ios::beg</td>
<td>SEEK_SET</td>
<td></td>
</tr>
<tr>
<td>basic_ios::cur</td>
<td>SEEK_CUR</td>
<td></td>
</tr>
<tr>
<td>basic_ios::end</td>
<td>SEEK_END</td>
<td></td>
</tr>
</tbody>
</table>

```cpp
pos_type seekpos(pos_type sp,
    ios_base::openmode which
        = ios_base::in | ios_base::out) override;
```

Alters the file position, if possible, to correspond to the position stored in sp (as described below). Altering the file position performs as follows:

1. if (om & ios_base::out) != 0, then update the output sequence and write any unshift sequence;
2. set the file position to sp as if by a call to fsetpos;
3. if (om & ios_base::in) != 0, then update the input sequence;

where om is the open mode passed to the last call to open(). The operation fails if is_open() returns false. If sp is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If sp has not been obtained by a previous successful call to one of the positioning functions (seekoff or seekpos) on the same file the effects are undefined.

Returns: sp on success. Otherwise returns pos_type(off_type(-1)).

```cpp
int sync() override;
```

Effects: If a put area exists, calls filebuf::overflow to write the characters to the file, then flushes the file as if by calling fflush(file). If a get area exists, the effect is implementation-defined.

```cpp
void imbue(const locale& loc) override;
```

Preconditions: If the file is not positioned at its beginning and the encoding of the current locale as determined by a_codecvt.encoding() is state-dependent (28.4.1.4.2) then that facet is the same as the corresponding facet of loc.

Effects: Causes characters inserted or extracted after this call to be converted according to loc until another call of imbue.

Remarks: This may require reconversion of previously converted characters. This in turn may require the implementation to be able to reconstruct the original contents of the file.

### 29.9.3 Class template basic_ifstream

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ifstream : public basic_istream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

            // 29.9.3.1, constructors
            basic_ifstream();
            explicit basic_ifstream(const char* s, 
                ios_base::openmode mode = ios_base::in);
            explicit basic_ifstream(const filesystem::path::value_type* s, 
                ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1
            explicit basic_ifstream(const string& s, 
                ios_base::openmode mode = ios_base::in);
    }
}
```
explicit basic_ifstream(const filesystem::path& s,
                   ios_base::openmode mode = ios_base::in);
basic_ifstream(const basic_ifstream&) = delete;
basic_ifstream(basic_ifstream&& rhs);

// 29.9.3.2, assign and swap
basic_ifstream& operator=(const basic_ifstream&) = delete;
basic_ifstream& operator=(basic_ifstream&& rhs);
void swap(basic_ifstream& rhs);

// 29.9.3.3, members
basic_filebuf<
charT, traits>* rdbuf() const;

bool is_open() const;
void open(const char* s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path::value_type* s,
          ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1
void open(const string& s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);
void close();
private:
    basic_filebuf<charT, traits> sb;  // exposition only
};

template<class charT, class traits>
void swap(basic_ifstream<charT, traits>& x,
          basic_ifstream<charT, traits>& y);

1 The class basic_ifstream<charT, traits> supports reading from named files. It uses a basic_filebuf<charT,
traits> object to control the associated sequence. For the sake of exposition, the maintained data is presented here
as:

— sb, the filebuf object.

29.9.3.1 Constructors

basic_ifstream();

Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1.1) and
sb with basic_filebuf<charT, traits>() (29.9.2.1).

explicit basic_ifstream(const char* s,
                        ios_base::openmode mode = ios_base::in);
explicit basic_ifstream(const filesystem::path::value_type* s,
                        ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1

Effects: Initializes the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1.1) and sb
with basic_filebuf<charT, traits>() (29.9.2.1), then calls rdbuf()->open(s, mode | ios_base::in).
If that function returns a null pointer, calls setstate(failbit).

explicit basic_ifstream(const string& s,
                        ios_base::openmode mode = ios_base::in);
explicit basic_ifstream(const filesystem::path& s,
                        ios_base::openmode mode = ios_base::in);

Effects: Equivalent to: basic_ifstream(s.c_str(), mode).

basic_ifstream(basic_ifstream&& rhs);

Effects: Move constructs the base class, and the contained basic_filebuf. Then calls basic_istream<charT,
traits>::set_rdbuf(addressof(sb)) to install the contained basic_filebuf.
### § 29.9.3.2  Assignment and swap

```
void swap(basic_ifstream& rhs);
```

**Effects:** Exchanges the state of `*this` and `rhs` by calling `basic_istream<char, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template<class charT, class traits>
void swap(basic_ifstream<charT, traits>& x,
          basic_ifstream<charT, traits>& y);
```

**Effects:** Equivalent to: `x.swap(y)`.

### § 29.9.3.3  Member functions

```
basic_filebuf<charT, traits>* rdbuf() const;
```

**Returns:** `const_cast<basic_filebuf<charT, traits>*>(addressof(sb)).`

```
bool is_open() const;
```

**Returns:** `rdbuf()->is_open()`.

```
void open(const char* s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path::value_type* s,
          ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1
```

**Effects:** Calls `rdbuf()->open(s, mode | ios_base::in)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)` (which may throw `ios_base::failure` (29.5.5.4)).

```
void open(const string& s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);
```

**Effects:** Calls `open(s.c_str(), mode)`.

```
void close();
```

**Effects:** Calls `rdbuf()->close()` and, if that function returns a null pointer, calls `setstate(failbit)` (which may throw `ios_base::failure` (29.5.5.4)).

### § 29.9.4  Class template basic_ofstream

```
namespace std {
template<class charT, class traits = char_traits<charT>>
class basic_ofstream : public basic_ostream<charT, traits> {
public:
  using char_type = charT;
  using int_type = typename traits::int_type;
  using pos_type = typename traits::pos_type;
  using off_type = typename traits::off_type;
  using traits_type = traits;

  // § 29.9.4.1, constructors
  basic_ofstream();
  explicit basic_ofstream(const char* s,
                          ios_base::openmode mode = ios_base::out);
  explicit basic_ofstream(const filesystem::path::value_type* s,  // wide systems only; see 29.9.1
                          ios_base::openmode mode = ios_base::out);
  explicit basic_ofstream(const string& s,  // wide systems only; see 29.9.1
                          ios_base::openmode mode = ios_base::out);
  explicit basic_ofstream(const filesystem::path& s,
                          ios_base::openmode mode = ios_base::out);
  basic_ofstream(const basic_ofstream&) = delete;
  basic_ofstream(basic_ofstream&& rhs);

  // § 29.9.4.2, assign and swap
  basic_ofstream& operator=(const basic_ofstream&) = delete;
  basic_ofstream& operator=(basic_ofstream&& rhs);
  void swap(basic_ofstream& rhs);
```

§ 29.9.4

1399
The class `basic_ofstream<charT, traits>` supports writing to named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

\[ \text{sb}, \text{the filebuf object.} \]

29.9.4.1 Constructors  

### basic_ofstream();

**Effects:** Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (29.7.5.1.1) and `sb` with `basic_filebuf<charT, traits>()` (29.9.2.1).

### explicit basic_ofstream(const char* s,  

**Effects:** Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))` (29.7.5.1.1) and `sb` with `basic_filebuf<charT, traits>()` (29.9.2.1), then calls `rdbuf()->open(s, mode | ios_base::out)`. If that function returns a null pointer, calls `setstate(failbit)`.

### explicit basic_ofstream(const filesystem::path::value_type* s,  

**Effects:** Equivalent to: `basic_ofstream(s.c_str(), mode)`.

### basic_ofstream(basic_ofstream&& rhs);

**Effects:** Move constructs the base class, and the contained `basic_filebuf`. Then calls `basic_ostream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_filebuf`.

29.9.4.2 Assignment and swap  

### void swap(basic_ofstream& rhs);

**Effects:** Exchanges the state of `*this` and `rhs` by calling `basic_ostream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

### template<class charT, class traits>  

**Effects:** Equivalent to: `x.swap(y)`.

29.9.5 Class template basic_fstream

namespace std {

```cpp
// 29.9.5.1, constructors
basic_fstream();
explicit basic_fstream(const char* s, ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(const filesystem::path::value_type* s, ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 29.9.1
explicit basic_fstream(const string& s, ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(const filesystem::path& s, ios_base::openmode mode = ios_base::in | ios_base::out);
```

```cpp
// 29.9.5.2, assign and swap
basic_fstream& operator=(const basic_fstream&) = delete;
basic_fstream& operator=(basic_fstream&& rhs);
void swap(basic_fstream& rhs);
```

```cpp
// 29.9.5.3, members
basic_filebuf<charT, traits>* rdbuf() const;
bool is_open() const;
void open(const char* s, ios_base::openmode mode = ios_base::in | ios_base::out);
```
The class template `basic_fstream<charT, traits>` supports reading and writing from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

\[ \text{(1.1)} \quad \text{sb, the basic_filebuf object.} \]

### 29.9.5.1 Constructors

**basic_fstream();**

*Effects:* Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (29.7.4.6.1) and `sb` with `basic_filebuf<charT, traits>()`.

**explicit basic_fstream(const char* s,**

*Effects:* Initializes the base class with `basic_iostream<charT, traits>(addressof(sb))` (29.7.4.6.1) and `sb` with `basic_filebuf<charT, traits>()`. Then calls `rdbuf()->open(s, mode)` if that function returns a null pointer, calls `setstate(failbit)`.

**explicit basic_fstream(const filesystem::path::value_type* s,**

*Effects:* Equivalent to: `basic_fstream(s.c_str(), mode)`.

**basic_fstream(basic_fstream&& rhs);**

*Effects:* Move constructs the base class, and the contained `basic_filebuf`. Then calls `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` to install the contained `basic_filebuf`.

### 29.9.5.2 Assignment and swap

**void swap(basic_fstream& rhs);**

*Effects:* Exchanges the state of `*this` and `rhs` by calling `basic_iostream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.
template<class charT, class traits>
    void swap(basic_fstream<charT, traits>& x,
              basic_fstream<charT, traits>& y);

    Effects: Equivalent to: x.swap(y).

29.9.5.3 Member functions

basic_filebuf<charT, traits>* rdbuf() const;
1
    Returns: const_cast&lt;basic_filebuf&lt;charT, traits>*&gt;(addressof(sb)).

bool is_open() const;
2
    Returns: rdbuf()->is_open().

void open(const char* s,
          ios_base::openmode mode = ios_base::in | ios_base::out);
void open(const filesystem::path::value_type* s,
          ios_base::openmode mode = ios_base::in | ios_base::out);  // wide systems only; see 29.9.1
3
    Effects: Calls rdbuf()&gt;open(s, mode). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure)(29.5.5.4).

void open(const string& s,
          ios_base::openmode mode = ios_base::in | ios_base::out);
void open(const filesystem::path& s,
          ios_base::openmode mode = ios_base::in | ios_base::out);
4
    Effects: Calls open(s.c_str(), mode).

void close();
5
    Effects: Calls rdbuf()->close() and, if that function returns a null pointer, calls setstate(failbit) (which may throw ios_base::failure)(29.5.5.4).

29.10 Synchronized output streams

29.10.1 Header &lt;syncstream&gt; synopsis

#include &lt;ostream&gt;  // see 29.7.2

namespace std {
    template<class charT, class traits = char_traits&lt;charT&gt;, class Allocator = allocator&lt;charT&gt;>
        class basic_syncbuf;

    using syncbuf = basic_syncbuf&lt;char&gt;;
    using wsyncbuf = basic_syncbuf&lt;wchar_t&gt;;

    template<class charT, class traits = char_traits&lt;charT&gt;, class Allocator = allocator&lt;charT&gt;>
        class basic_osyncstream;

    using osyncstream = basic_osyncstream&lt;char&gt;;
    using wosyncstream = basic_osyncstream&lt;wchar_t&gt;;
}

1 The header &lt;syncstream&gt; provides a mechanism to synchronize execution agents writing to the same stream.

29.10.2 Class template basic_syncbuf

29.10.2.1 Overview

namespace std {
    template<class charT, class traits = char_traits&lt;charT&gt;, class Allocator = allocator&lt;charT&gt;>
        class basic_syncbuf : public basic_streambuf&lt;charT, traits&gt; {
            public:
                using char_type = charT;

§ 29.10.2.1
using int_type = typename traits::int_type;
using pos_type = typename traits::pos_type;
using off_type = typename traits::off_type;
using traits_type = traits;
using allocator_type = Allocator;
using streambuf_type = basic_streambuf<charT, traits>;

// 29.10.2.2, construction and destruction
basic_syncbuf()
    : basic_syncbuf(nullptr) {}
explicit basic_syncbuf(streambuf_type* obuf)
    : basic_syncbuf(obuf, Allocator()) {}
basic_syncbuf(streambuf_type*, const Allocator&);
basic_syncbuf(basic_syncbuf&&);
~basic_syncbuf();

// 29.10.2.3, assignment and swap
basic_syncbuf& operator=(basic_syncbuf&&);
void swap(basic_syncbuf&);

// 29.10.2.4, member functions
bool emit();
streambuf_type* get_wrapped() const noexcept;
allocator_type get_allocator() const noexcept;
void set_emit_on_sync(bool) noexcept;

protected:
// 29.10.2.5, overridden virtual functions
int sync() override;

private:
streambuf_type* wrapped;  // exposition only
bool emit_on_sync{};       // exposition only
);

// 29.10.2.6, specialized algorithms
template<class charT, class traits, class Allocator>
void swap(basic_syncbuf<charT, traits, Allocator>&,
basic_syncbuf<charT, traits, Allocator>&);

Class template basic_syncbuf stores character data written to it, known as the associated output, into internal buffers allocated using the object’s allocator. The associated output is transferred to the wrapped stream buffer object *wrapped when emit() is called or when the basic_syncbuf object is destroyed. Such transfers are atomic with respect to transfers by other basic_syncbuf objects with the same wrapped stream buffer object.

29.10.2.2 Construction and destruction  [synostream.syncbuf.cons]
basic_syncbuf(streambuf_type* obuf, const Allocator& allocator);

Effects: Sets wrapped to obuf.
Postconditions: get_wrapped() == obuf and get_allocator() == allocator are true.
Throws: Nothing unless an exception is thrown by the construction of a mutex or by memory allocation.
Remarks: A copy of allocator is used to allocate memory for internal buffers holding the associated output.

basic_syncbuf(basic_syncbuf&& other);

Postconditions: The value returned by this->get_wrapped() is the value returned by other.get_wrapped() prior to calling this constructor. Output stored in other prior to calling this constructor will be stored in *this afterwards. other.rdbuf()->pbase() == other.rdbuf()->pptr() and other.get_wrapped() == nullptr are true.
Remarks: This constructor disassociates other from its wrapped stream buffer, ensuring destruction of other produces no output.

~basic_syncbuf();

Effects: Calls emit().

Throws: Nothing. If an exception is thrown from emit(), the destructor catches and ignores that exception.

29.10.2.3 Assignment and swap

basic_syncbuf& operator=(basic_syncbuf&& rhs) noexcept;

Effects: Calls emit() then move assigns from rhs. After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (29.10.2.2).

Postconditions:

1. rhs.get_wrapped() == nullptr is true.
2. this->get_allocator() == rhs.get_allocator() is true when allocator_traits<Allocator>::propagate_on_container_move_assignment::value is true; otherwise, the allocator is unchanged.

Returns: *this.

Remarks: This assignment operator disassociates rhs from its wrapped stream buffer, ensuring destruction of rhs produces no output.

void swap(basic_syncbuf& other) noexcept;

Preconditions: Either allocator_traits<Allocator>::propagate_on_container_swap::value is true or this->get_allocator() == other.get_allocator() is true.

Effects: Exchanges the state of *this and other.

29.10.2.4 Member functions

bool emit();

Effects: Atomically transfers the associated output of *this to the stream buffer *wrapped, so that it appears in the output stream as a contiguous sequence of characters. wrapped->pubsync() is called if and only if a call was made to sync() since the most recent call to emit(), if any.

Postconditions: On success, the associated output is empty.

Returns: true if all of the following conditions hold; otherwise false:

1. wrapped == nullptr is false.
2. All of the characters in the associated output were successfully transferred.
3. The call to wrapped->pubsync() (if any) succeeded.

Synchronization: All emit() calls transferring characters to the same stream buffer object appear to execute in a total order consistent with the “happens before” relation (6.9.2.1), where each emit() call synchronizes with subsequent emit() calls in that total order.

Remarks: May call member functions of wrapped while holding a lock uniquely associated with wrapped.

streambuf_type* get_wrapped() const noexcept;

Returns: wrapped.

allocator_type get_allocator() const noexcept;

Returns: A copy of the allocator that was set in the constructor or assignment operator.

void set_emit_on_sync(bool b) noexcept;

Effects: emit_on_sync = b.
29.10.2.5 Overridden virtual functions

```cpp
int sync() override;
```

1 Effects: Records that the wrapped stream buffer is to be flushed. Then, if emit_on_sync is true, calls emit().
2 [Note: If emit_on_sync is false, the actual flush is delayed until a call to emit(). — end note]

29.10.2.6 Specialized algorithms

```cpp
template<class charT, class traits, class Allocator>
void swap(basic_syncbuf<charT, traits, Allocator>& a, basic_syncbuf<charT, traits, Allocator>& b) noexcept;
```

1 Effects: Equivalent to a.swap(b).

29.10.3 Class template basic_osyncstream

29.10.3.1 Overview

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
    class basic_osyncstream : public basic_ostream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;
            using streambuf_type = basic_streambuf<charT, traits>;
            using syncbuf_type = basic_syncbuf<charT, traits, Allocator>;

            public:
                using allocator_type = Allocator;
                using streambuf_type = basic_streambuf<charT, traits>;
                using syncbuf_type = basic_syncbuf<charT, traits, Allocator>;

            // 29.10.3.2, construction and destruction
            basic_osyncstream(streambuf_type*, const Allocator&);
            explicit basic_osyncstream(streambuf_type* obuf) : basic_osyncstream(obuf, Allocator()) {}
            basic_osyncstream(basic_ostream<charT, traits>&& os, const Allocator& allocator) : basic_osyncstream(os.rdbuf(), allocator) {}
            explicit basic_osyncstream(basic_ostream<charT, traits>&& os) : basic_osyncstream(os, Allocator()) {}
            basic_osyncstream(basic_osyncstream&&) noexcept;
            `basic_osyncstream();`

            // assignment
            basic_osyncstream& operator=(basic_osyncstream&&) noexcept;

            // 29.10.3.3, member functions
            void emit();
            streambuf_type* get_wrapped() const noexcept;
            syncbuf_type* rdbuf() const noexcept { return const_cast<syncbuf_type*>(addressof(sb)); }

            private:
                syncbuf_type sb; // exposition only
            ;
    }
```

1 Allocator shall meet the Cpp17Allocator requirements (Table 36).
2 [Example: A named variable can be used within a block statement for streaming.
```cpp
{ 
    osyncstream bout(cout);
    bout << "Hello, ";
    bout << "World!";
    bout << endl; // flush is noted
}
bout << "and more!\n";
} // characters are transferred and cout is flushed
— end example]

3 [Example: A temporary object can be used for streaming within a single statement.

osyncstream(cout) << "Hello, " << "World!" << '\n';
In this example, cout is not flushed. — end example]

29.10.3.2 Construction and destruction

basic_osyncstream(streambuf_type* buf, const Allocator& allocator);
1 Effects: Initializes sb from buf and allocator. Initializes the base class with basic_ostream<charT, traits>(addressof(sb)).
2 [Note: The member functions of the provided stream buffer might be called from emit() while a lock is held. Care should be taken to ensure that this does not result in deadlock. — end note]
3 Postconditions: get_wrapped() == buf is true.

basic_osyncstream(basic_osyncstream&& other) noexcept;
4 Effects: Move constructs the base class and sb from the corresponding subobjects of other, and calls basic_ostream<charT, traits>::set_rdbuf(addressof(sb)).
5 Postconditions: The value returned by get_wrapped() is the value returned by os.get_wrapped() prior to calling this constructor. nullptr == other.get_wrapped() is true.

29.10.3.3 Member functions

void emit();
1 Effects: Calls sb.emit(). If that call returns false, calls setstate(ios_base::badbit).
2 [Example: A flush on a basic_osyncstream does not flush immediately:

{ osyncstream bout(cout);
  bout << "Hello," << '\n'; // no flush
  bout.emit(); // characters transferred; cout not flushed
  bout << "World!" << endl; // flush noted; cout not flushed
  bout.emit(); // characters transferred; cout flushed
  bout << "Greetings." << '\n'; // no flush
} // characters transferred; cout not flushed
— end example]

3 [Example: The function emit() can be used to handle exceptions from operations on the underlying stream.

{ osyncstream bout(cout);
  bout << "Hello, " << "World!" << '\n';
  try {
    bout.emit();
  } catch (...) {
    // handle exception
  }
}
— end example]

streambuf_type* get_wrapped() const noexcept;
4 Returns: sb.get_wrapped().
5 [Example: Obtaining the wrapped stream buffer with get_wrapped() allows wrapping it again with an osyncstream. For example,

{ osyncstream bout1(cout);
  bout1 << "Hello, ";

§ 29.10.3.3
{ osyncstream(bout1.get_wrapped()) << "Goodbye, " << "Planet!" << 'n';
}
bout1 << "World!" << 'n';
}
produces the uninterleaved output
Goodbye, Planet!
Hello, World!
— end example]
29.11.2.3 File system race behavior

A file system race is the condition that occurs when multiple threads, processes, or computers interleave access and modification of the same object within a file system. Behavior is undefined if calls to functions provided by subclause 29.11 introduce a file system race.

If the possibility of a file system race would make it unreliable for a program to test for a precondition before calling a function described herein, Preconditions: is not specified for the function. [Note: As a design practice, preconditions are not specified when it is unreasonable for a program to detect them prior to calling the function.—end note]

29.11.3 Normative references

Subclause 29.11 mentions commercially available operating systems for purposes of exposition.

29.11.4 Requirements

Throughout subclause 29.11, char, wchar_t, char8_t, char16_t, and char32_t are collectively called encoded character types.

Functions with template parameters named EcharT shall not participate in overload resolution unless EcharT is one of the encoded character types.

Template parameters named InputIterator shall meet the Cpp17InputIterator requirements (23.3.5.2) and shall have a value type that is one of the encoded character types.

[Note: Use of an encoded character type implies an associated character set and encoding. Since signed char and unsigned char have no implied character set and encoding, they are not included as permitted types.—end note]

Template parameters named Allocator shall meet the Cpp17Allocator requirements (Table 36).

29.11.4.1 Namespaces and headers

Unless otherwise specified, references to entities described in subclause 29.11 are assumed to be qualified with ::std::filesystem::.

29.11.5 Header <filesystem> synopsis

#include <compare> // see 17.11.1

namespace std::filesystem {
    // 29.11.7, paths
    class path;
    // 29.11.7.7, path non-member functions
    void swap(path& lhs, path& rhs) noexcept;
    size_t hash_value(const path& p) noexcept;
    // 29.11.8, filesystem errors
    class filesystem_error;
    // 29.11.11, directory entries
    class directory_entry;
    // 29.11.12, directory iterators
    class directory_iterator;
    // 29.11.12.2, range access for directory iterators
    directory_iterator begin(directory_iterator iter) noexcept;
    directory_iterator end(const directory_iterator&) noexcept;
    // 29.11.13, recursive directory iterators
    class recursive_directory_iterator;
    // 29.11.13.2, range access for recursive directory iterators
    recursive_directory_iterator begin(recursive_directory_iterator iter) noexcept;
    recursive_directory_iterator end(const recursive_directory_iterator&) noexcept;

1 Implementations should ensure that the resolution and range of file_time_type reflect the operating system dependent resolution and range of file time values.

29.11.6 Error reporting [fs.err.report]

Filesystem library functions often provide two overloads, one that throws an exception to report file system errors, and another that sets an error_code. [Note: This supports two common use cases:

(1.1) Uses where file system errors are truly exceptional and indicate a serious failure. Throwing an exception is an appropriate response.

(1.2) Uses where file system errors are routine and do not necessarily represent failure. Returning an error code is the most appropriate response. This allows application specific error handling, including simply ignoring the error.

— end note]

Functions not having an argument of type error_code& handle errors as follows, unless otherwise specified:

(2.1) When a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, an exception of type filesystem_error shall be thrown. For functions with a single path argument, that argument shall be passed to the filesystem_error constructor with a single path argument. For functions with two path arguments, the first of these arguments shall be passed to the filesystem_error constructor as the path1 argument, and the second shall be passed as the path2 argument. The filesystem_error constructor's error_code argument is set as appropriate for the specific operating system dependent error.
— Failure to allocate storage is reported by throwing an exception as described in 16.5.5.13.

— Destructors throw nothing.

Functions having an argument of type `error_code&` handle errors as follows, unless otherwise specified:

— If a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, the `error_code&` argument is set as appropriate for the specific operating system dependent error. Otherwise, `clear()` is called on the `error_code&` argument.

### 29.11.7 Class `path`

1. An object of class `path` represents a path and contains a pathname. Such an object is concerned only with the lexical and syntactic aspects of a path. The path does not necessarily exist in external storage, and the pathname is not necessarily valid for the current operating system or for a particular file system.

2. [Note: Class `path` is used to support the differences between the string types used by different operating systems to represent pathnames, and to perform conversions between encodings when necessary. — end note]

3. A `path` is a sequence of elements that identify the location of a file within a filesystem. The elements are the `root-name_opt`, `root-directory_opt`, and an optional sequence of filenames (29.11.7.1). The maximum number of elements in the sequence is operating system dependent (29.11.2.2).

4. An `absolute path` is a path that unambiguously identifies the location of a file without reference to an additional starting location. The elements of a path that determine if it is absolute are operating system dependent. A `relative path` is a path that is not absolute, and as such, only unambiguously identifies the location of a file when resolved relative to an implied starting location. The elements of a path that determine if it is relative are operating system dependent. [Note: Pathnames “.” and “..” are relative paths. — end note]

5. A `pathname` is a character string that represents the name of a path. Pathnames are formatted according to the generic pathname format grammar (29.11.7.1) or according to an operating system dependent `native pathname format` accepted by the host operating system.

6. Pathname resolution is the operating system dependent mechanism for resolving a pathname to a particular file in a file hierarchy. There may be multiple pathnames that resolve to the same file. [Example: POSIX specifies the mechanism in section 4.11, Pathname resolution. — end example]

```cpp
namespace std::filesystem {
    class path {
    public:
        using value_type = see below;
        using string_type = basic_string<value_type>;
        static constexpr value_type preferred_separator = see below;

        // 29.11.9.1, enumeration format
        enum format;

        // 29.11.7.4.1, constructors and destructor
        path() noexcept;
        path(const path& p);
        path(path&& p) noexcept;
        path(string_type&& source, format fmt = auto_format);
        template<class Source>
            path(const Source& source, format fmt = auto_format);
        template<class InputIterator>
            path(InputIterator first, InputIterator last, format fmt = auto_format);
        template<class InputIterator>
            path(InputIterator first, InputIterator last, const locale& loc, format fmt = auto_format);
        ~path();

        // 29.11.7.4.2, assignments
        path& operator=(const path& p);
        path& operator=(path&& p) noexcept;
        path& operator=(string_type&& source);
        path& assign(string_type&& source);

    private:
        // ...

    operator>>(basic_istream<charT, traits>& is, path& p);
}

value_type is a typedef for the operating system dependent encoded character type used to represent pathnames.

The value of the preferred_separator member is the operating system dependent preferred_separator character (29.11.7.1).
Example: For POSIX-based operating systems, value_type is char and preferred_separator is the slash character (\'/\'). For Windows-based operating systems, value_type is wchar_t and preferred separator is the backslash character (L'\'). — end example

29.11.7.1 Generic pathname format

pathname:
  root-name\opt root-directory\opt relative-path

root-name:
  operating system dependent sequences of characters
  implementation-defined sequences of characters

root-directory:
  directory-separator

relative-path:
  filename
  filename directory-separator relative-path
  an empty path

filename:
  non-empty sequence of characters other than directory-separator characters

directory-separator:
  preferred-separator directory-separator\opt
  fallback-separator directory-separator\opt

preferred-separator:
  operating system dependent directory separator character

fallback-separator:
  /, if preferred-separator is not /

A filename is the name of a file. The dot and dot-dot filenames, consisting solely of one and two period characters respectively, have special meaning. The following characteristics of filenames are operating system dependent:

(1.1) — The permitted characters. [Example: Some operating systems prohibit the ASCII control characters (0x00 – 0x1F) in filenames. — end example] [Note: For wide portability, users may wish to limit filename characters to the POSIX Portable Filename Character Set: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z a b c d e f g h i j k l m n o p q r s t u v w x y z 0 1 2 3 4 5 6 7 8 9 . _ - — end note]

(1.2) — The maximum permitted length.

(1.3) — Filenames that are not permitted.

(1.4) — Filenames that have special meaning.

(1.5) — Case awareness and sensitivity during path resolution.

(1.6) — Special rules that may apply to file types other than regular files, such as directories.

Except in a root-name, multiple successive directory-separator characters are considered to be the same as one directory-separator character.

The dot filename is treated as a reference to the current directory. The dot-dot filename is treated as a reference to the parent directory. What the dot-dot filename refers to relative to root-directory is implementation-defined. Specific filenames may have special meanings for a particular operating system.

A root-name identifies the starting location for pathname resolution (29.11.7). If there are no operating system dependent root-names, at least one implementation-defined root-name is required. [Note: Many operating systems define a name beginning with two directory-separator characters as a root-name that identifies network or other resource locations. Some operating systems define a single letter followed by a colon as a drive specifier – a root-name identifying a specific device such as a disk drive. — end note]

If a root-name is otherwise ambiguous, the possibility with the longest sequence of characters is chosen. [Note: On a POSIX-like operating system, it is impossible to have a root-name and a relative-path without an intervening root-directory element. — end note]

Normalization of a generic format pathname means:

1. If the path is empty, stop.
2. Replace each slash character in the root-name with a preferred-separator.

3. Replace each directory-separator with a preferred-separator. [Note: The generic pathname grammar (29.11.7.1) defines directory-separator as one or more slashes and preferred-separators. — end note]

4. Remove each dot filename and any immediately following directory-separator.

5. As long as any appear, remove a non-dot-dot filename immediately followed by a directory-separator and a dot-dot filename, along with any immediately following directory-separator.

6. If there is a root-directory, remove all dot-dot filenames and any directory-separators immediately following them. [Note: These dot-dot filenames attempt to refer to nonexistent parent directories. — end note]

7. If the last filename is dot-dot, remove any trailing directory-separator.

8. If the path is empty, add a dot.

The result of normalization is a path in normal form, which is said to be normalized.

29.11.7.2 Conversions

29.11.7.2.1 Argument format conversions

[fs.path.cvt]

1 [Note: The format conversions described in this subclause are not applied on POSIX-based operating systems because on these systems:

(1.1) — The generic format is acceptable as a native path.

(1.2) — There is no need to distinguish between native format and generic format in function arguments.

(1.3) Paths for regular files and paths for directories share the same syntax.

— end note]

2 Several functions are defined to accept detected-format arguments, which are character sequences. A detected-format argument represents a path using either a pathname in the generic format (29.11.7.1) or a pathname in the native format (29.11.7). Such an argument is taken to be in the generic format if and only if it matches the generic format and is not acceptable to the operating system as a native path.

3 [Note: Some operating systems may have no unambiguous way to distinguish between native format and generic format arguments. This is by design as it simplifies use for operating systems that do not require disambiguation. An implementation for an operating system where disambiguation is required is permitted to distinguish between the formats. — end note]

4 Pathnames are converted as needed between the generic and native formats in an operating-system-dependent manner. Let \( G(n) \) and \( N(g) \) in a mathematical sense be the implementation’s functions that convert native-to-generic and generic-to-native formats respectively. If \( g=G(n) \) for some \( n \), then \( G(N(g))=g \); if \( n=N(g) \) for some \( g \), then \( N(G(n))=n \). [Note: Neither \( G \) nor \( N \) need be invertible. — end note]

5 If the native format requires paths for regular files to be formatted differently from paths for directories, the path shall be treated as a directory path if its last element is a directory-separator, otherwise it shall be treated as a path to a regular file.

6 [Note: A path stores a native format pathname (29.11.7.4.6) and acts as if it also stores a generic format pathname, related as given below. The implementation may generate the generic format pathname based on the native format pathname (and possibly other information) when requested. — end note]

7 When a path is constructed from or is assigned a single representation separate from any path, the other representation is selected by the appropriate conversion function (\( G \) or \( N \)).

8 When the (new) value \( p \) of one representation of a path is derived from the representation of that or another path, a value \( q \) is chosen for the other representation. The value \( q \) converts to \( p \) (by \( G \) or \( N \) as appropriate) if any such value does so; \( q \) is otherwise unspecified. [Note: If \( q \) is the result of converting any path at all, it is the result of converting \( p \). — end note]

29.11.7.2.2 Type and encoding conversions

[fs.path.cvt]

1 The native encoding of an ordinary character string is the operating system dependent current encoding for pathnames (29.11.7). The native encoding for wide character strings is the implementation-defined execution wide-character set encoding (5.3).

2 For member function arguments that take character sequences representing paths and for member functions returning strings, value type and encoding conversion is performed if the value type of the argument or return value differs
from `path::value_type`. For the argument or return value, the method of conversion and the encoding to be converted to is determined by its value type:

- **char**: The encoding is the native ordinary encoding. The method of conversion, if any, is operating system dependent. [Note: For POSIX-based operating systems `path::value_type` is `char` so no conversion from `char` value type arguments or to `char` value type return values is performed. For Windows-based operating systems, the native ordinary encoding is determined by calling a Windows API function. — end note] [Note: This results in behavior identical to other C and C++ standard library functions that perform file operations using ordinary character strings to identify paths. Changing this behavior would be surprising and error prone. — end note]

- **wchar_t**: The encoding is the native wide encoding. The method of conversion is unspecified. [Note: For Windows-based operating systems `path::value_type` is `wchar_t` so no conversion from `wchar_t` value type arguments or to `wchar_t` value type return values is performed. — end note]

- **char8_t**: The encoding is UTF-8. The method of conversion is unspecified.

- **char16_t**: The encoding is UTF-16. The method of conversion is unspecified.

- **char32_t**: The encoding is UTF-32. The method of conversion is unspecified.

If the encoding being converted to has no representation for source characters, the resulting converted characters, if any, are unspecified. Implementations should not modify member function arguments if already of type `path::value_type`.

### 29.11.7.3 Requirements

In addition to the requirements (29.11.4), function template parameters named `Source` shall be one of:

- **basic_string<EcharT, traits, Allocator>**: A function argument const `Source& source` shall have an effective range `[source.begin(), source.end())`.

- **basic_string_view<EcharT, traits>**: A function argument const `Source& source` shall have an effective range `[source.begin(), source.end())`.

- **A type meeting the Cpp17InputIterator requirements that iterates over a NTCTS. The value type shall be an encoded character type. A function argument const `Source& source` shall have an effective range `[source, end)` where `end` is the first iterator value with an element value equal to `iterator_traits<Source>::value_type()`.

- **A character array that after array-to-pointer decay results in a pointer to the start of a NTCTS. The value type shall be an encoded character type. A function argument const `Source& source` shall have an effective range `[source, end)` where `end` is the first iterator value with an element value equal to `iterator_traits<decay_t<Source>>::value_type()`.

Functions taking template parameters named `Source` shall not participate in overload resolution unless `Source` denotes a type other than `path`, and either

- `Source` is a specialization of `basic_string` or `basic_string_view`, or

- the `qualified-id` `iterator_traits<decay_t<Source>>::value_type` is valid and denotes a possibly const encoded character type (13.10.2).

[Note: See path conversions (29.11.7.2) for how the value types above and their encodings convert to `path::value_type` and its encoding. — end note]

Arguments of type `Source` shall not be null pointers.

### 29.11.7.4 Members

#### 29.11.7.4.1 Constructors

- `path() noexcept;

  Postconditions: empty() == true.

- `path(const path& p);

  Effects: Constructs an object of class `path` having the same pathname in the native and generic formats, respectively, as the original value of `p`. In the second form, `p` is left in a valid but unspecified state.
path(string_type&& source, format fmt = auto_format);

Effects: Constructs an object of class path for which the pathname in the detected-format of source has the original value of source (29.11.7.2.1), converting format if required (29.11.7.2.1). source is left in a valid but unspecified state.

template<class Source>
path(const Source& source, format fmt = auto_format);
template<class InputIterator>
path(InputIterator first, InputIterator last, format fmt = auto_format);

Effects: Let s be the effective range of source (29.11.7.3) or the range [first, last), with the encoding converted if required (29.11.7.2). Finds the detected-format of s (29.11.7.2.1) and constructs an object of class path for which the pathname in that format is s.

template<class Source>
path(const Source& source, const locale& loc, format fmt = auto_format);
template<class InputIterator>
path(InputIterator first, InputIterator last, const locale& loc, format fmt = auto_format);

Mandates: The value type of Source and InputIterator is char.

Effects: Let s be the effective range of source or the range [first, last), after converting the encoding as follows:

1. If value_type is wchar_t, converts to the native wide encoding (29.11.7.2.2) using the codecvt<wchar_t, char, mbstate_t> facet of loc.
2. Otherwise a conversion is performed using the codecvt<wchar_t, char, mbstate_t> facet of loc, and then a second conversion to the current ordinary encoding.

Finds the detected-format of s (29.11.7.2.1) and constructs an object of class path for which the pathname in that format is s.

[Example: A string is to be read from a database that is encoded in ISO/IEC 8859-1, and used to create a directory:

```cpp
namespace fs = std::filesystem;
std::string latin1_string = read_latin1_data();
codecvt_8859_1<wchar_t> latin1_facet;
std::locale latin1_locale(std::locale(), latin1_facet);
fs::create_directory(fs::path(latin1_string, latin1_locale));
```

For POSIX-based operating systems, the path is constructed by first using latin1_facet to convert ISO/IEC 8859-1 encoded latin1_string to a wide character string in the native wide encoding (29.11.7.2.2). The resulting wide string is then converted to an ordinary character pathname string in the current native ordinary encoding. If the native wide encoding is UTF-16 or UTF-32, and the current native ordinary encoding is UTF-8, all of the characters in the ISO/IEC 8859-1 character set will be converted to their Unicode representation, but for other native ordinary encodings some characters may have no representation.

For Windows-based operating systems, the path is constructed by using latin1_facet to convert ISO/IEC 8859-1 encoded latin1_string to a UTF-16 encoded wide character pathname string. All of the characters in the ISO/IEC 8859-1 character set will be converted to their Unicode representation. — end example]
Effects: Sets the pathname in the detected-format of source to the original value of source. source is left in a valid but unspecified state.

Returns: *this.

template<class Source>
    path& operator=(const Source& source);

template<class Source>
    path& assign(const Source& source);

template<class InputIterator>
    path& assign(InputIterator first, InputIterator last);

Effects: Let s be the effective range of source (29.11.7.3) or the range [first, last), with the encoding converted if required (29.11.7.2). Finds the detected-format of s (29.11.7.2.1) and sets the pathname in that format to s.

Returns: *this.

29.11.7.4.3 Appends

The append operations use operator/= to denote their semantic effect of appending preferred-separator when needed.

Effects: If p.is_absolute() || (p.has_root_name() && p.root_name() != root_name()), then operator=(p).

Otherwise, modifies *this as if by these steps:

1. If p.has_root_directory(), then removes any root directory and relative path from the generic format pathname. Otherwise, if !has_root_directory() && is_absolute() is true or if has_filename() is true, then appends path::preferred_separator to the generic format pathname.

2. Then appends the native format pathname of p, omitting any root-name from its generic format pathname, to the native format pathname.

[Example: Even if //host is interpreted as a root-name, both of the paths path("//host")/"foo" and path("//host/ ")/"foo" equal "/host/foo" (although the former might use backslash as the preferred separator).

Expression examples:

// On POSIX,
    path("foo") /= path(""); // yields path("foo")
    path("foo") /= path(""); // yields path("/bar")

// On Windows,
    path("foo") /= path(""); // yields path("foo\")
    path("foo") /= path(""); // yields path("/bar")
    path("foo") /= path(""); // yields path("c:\")
    path("c:\") /= path(""); // yields path("c:\")
    path("c:foo") /= path(""); // yields path("c:bar")
    path("c:foo") /= path(""); // yields path("c:foo\bar")

— end example]

Returns: *this.

template<class Source>
    path& operator=(const Source& source);

template<class Source>
    path& append(const Source& source);

Effects: Equivalent to: return operator=(path(source));

template<class InputIterator>
    path& append(InputIterator first, InputIterator last);

Effects: Equivalent to: return operator=(path(first, last));
29.11.7.4.4 Concatenation

```
class path
path& operator+=(const path& x);
path& operator+=(const string_type& x);
path& operator+=(basic_string_view<value_type> x);
path& operator+=(const value_type* x);
template<class Source>
  path& operator+=(const Source& x);
template<class Source>
  path& concat(const Source& x);
```

1. **Effects**: Appends path(x).native() to the pathname in the native format. [Note: This directly manipulates the value of native() and may not be portable between operating systems. — end note]

2. **Returns**: *this.

```
path& operator+=(value_type x);
template<class EcharT>
  path& operator+=(EcharT x);
```

3. **Effects**: Equivalent to: return *this += basic_string_view(&x, 1);

```
template<class InputIterator>
  path& concat(InputIterator first, InputIterator last);
```

4. **Effects**: Equivalent to: return *this += path(first, last);

29.11.7.4.5 Modifiers

```
void clear() noexcept;
  Postconditions: empty() == true.

path& make_preferred();
  Effects: Each directory-separator of the pathname in the generic format is converted to preferred-separator.
  Returns: *this.
```

[Example:
```
  path p("foo/bar");
  std::cout << p << \n;
  p.make_preferred();
  std::cout << p << \n;
  On an operating system where preferred-separator is a slash, the output is:
  "foo/bar"
  "foo/bar"
```

On an operating system where preferred-separator is a backslash, the output is:
```
"foo/bar"
"foo\bar"
```

— end example]

```
path& remove_filename();
  Effects: Remove the generic format pathname of filename() from the generic format pathname.
  Postconditions: !has_filename().
  Returns: *this.
```

[Example:
```
  path("foo/bar").remove_filename(); // yields "foo/"
  path("foo/").remove_filename(); // yields "foo/"
  path("/foo").remove_filename(); // yields "/"
  path("").remove_filename(); // yields "/
```

— end example]
path& replace_filename(const path& replacement);

Effects: Equivalent to:
  remove_filename();
  operator/=(replacement);

Returns: *this.

[Example:
  path("/foo").replace_filename("bar");  // yields "/bar" on POSIX
  path("/").replace_filename("bar");    // yields "/bar" on POSIX
  — end example]

path& replace_extension(const path& replacement = path());

Effects:
  — Any existing extension() (29.11.7.4.9) is removed from the pathname in the generic format, then
  — If replacement is not empty and does not begin with a dot character, a dot character is appended to the
    pathname in the generic format, then
  — operator+=replacement);

Returns: *this.

void swap(path& rhs) noexcept;

Effects: Swaps the contents (in all formats) of the two paths.

Complexity: Constant time.

29.11.7.4.6 Native format observers [fs.path.native.obs]
The string returned by all native format observers is in the native pathname format (29.11.7).

const string_type& native() const noexcept;

Returns: The pathname in the native format.

const value_type* c_str() const noexcept;

Effects: Equivalent to: return native().c_str();

operator string_type() const;

Returns: native().

[Note: Conversion to string_type is provided so that an object of class path can be given as an argument to
existing standard library file stream constructors and open functions. — end note]

template<class EcharT, class traits = char_traits<EcharT>,
  class Allocator = allocator<EcharT>>
basic_string<EcharT, traits, Allocator>
  string(const Allocator& a = Allocator()) const;

Returns: native().

Remarks: All memory allocation, including for the return value, shall be performed by a. Conversion, if any, is
specified by 29.11.7.2.

std::string string() const;
std::wstring wstring() const;
std::u8string u8string() const;
std::u16string u16string() const;
std::u32string u32string() const;

Returns: native().

Remarks: Conversion, if any, is performed as specified by 29.11.7.2.

29.11.7.4.7 Generic format observers [fs.path.generic.obs]
Generic format observer functions return strings formatted according to the generic pathname format (29.11.7.1). A
single slash (’/’) character is used as the directory-separator.
Example: On an operating system that uses backslash as its preferred-separator, path("foo\bar").generic_string() returns "foo/bar". — end example

template<class EcharT, class traits = char_traits<EcharT>,
class Allocator = allocator<EcharT>>
basic_string<EcharT, traits, Allocator>
generic_string(const Allocator& a = Allocator()) const;

Returns: The pathname in the generic format.

Remarks: All memory allocation, including for the return value, shall be performed by a. Conversion, if any, is specified by 29.11.7.2.

std::string generic_string() const;
std::wstring generic_wstring() const;
std::u8string generic_u8string() const;
std::u16string generic_u16string() const;
std::u32string generic_u32string() const;

Returns: The pathname in the generic format.

Remarks: Conversion, if any, is specified by 29.11.7.2.

29.11.7.4.8 Compare [fs.path.compare]

int compare(const path& p) const noexcept;

Returns:
(1.1) Let rootNameComparison be the result of this->root_name().native().compare(p.root_name().native()). If rootNameComparison is not 0, rootNameComparison.
(1.2) Otherwise, if !this->has_root_directory() and p.has_root_directory(), a value less than 0.
(1.3) Otherwise, if this->has_root_directory() and !p.has_root_directory(), a value greater than 0.
(1.4) Otherwise, if native() for the elements of this->relative_path() are lexicographically less than native() for the elements of p.relative_path(), a value less than 0.
(1.5) Otherwise, if native() for the elements of this->relative_path() are lexicographically greater than native() for the elements of p.relative_path(), a value greater than 0.
(1.6) Otherwise, 0.

Effects: Equivalent to: return compare(path(s));

29.11.7.4.9 Decomposition [fs.path.decompose]

path root_name() const;

Returns: root-name, if the pathname in the generic format includes root-name, otherwise path().

path root_directory() const;

Returns: root-directory, if the pathname in the generic format includes root-directory, otherwise path().

path root_path() const;

Returns: root_name() / root_directory().

path relative_path() const;

Returns: A path composed from the pathname in the generic format, if empty() is false, beginning with the first filename after root_path(). Otherwise, path().
path parent_path() const;

Returns: *this if has_relative_path() is false, otherwise a path whose generic format pathname is the longest prefix of the generic format pathname of *this that produces one fewer element in its iteration.

path filename() const;

Returns: relative_path().empty() ? path() : *--end().

[Example:
path("/foo/bar.txt").filename();  // yields "bar.txt"
path("/foo/bar").filename();   // yields "bar"
path("/foo/bar/").filename();  // yields ""
path("//host").filename();     // yields ""
path(".").filename();          // yields "."
path("..").filename();         // yields ".."
— end example]

path stem() const;

Returns: Let f be the generic format pathname of filename(). Returns a path whose pathname in the generic format is
— f, if it contains no periods other than a leading period or consists solely of one or two periods;
— otherwise, the prefix of f ending before its last period.

[Example:
std::cout << path("/foo/bar.txt").stem(); // outputs "bar"
path p = "foo.barbaz.tar";
for (; !p.extension().empty(); p = p.stem())
    std::cout << p.extension() << 
// outputs: .tar
// .baz
// .bar
— end example]

path extension() const;

Returns: A path whose pathname in the generic format is the suffix of filename() not included in stem().

[Example:
path("/foo/bar.txt").extension();  // yields ".txt" and stem() is "bar"
path("/foo/bar").extension();     // yields "" and stem() is "bar"
path("/foo/profile").extension(); // yields "" and stem() is ".profile"
path("bar").extension();         // yields "" and stem() is "bar"
path("..bar").extension();       // yields ".bar" and stem() is " ."
— end example]

[Note: The period is included in the return value so that it is possible to distinguish between no extension and an empty extension. — end note]

[Note: On non-POSIX operating systems, for a path p, it may not be the case that p.stem() + p.extension() == p.filename(), even though the generic format pathnames are the same. — end note]

29.11.7.4.10 Query [fs.path.query]

[[nodiscard]] bool empty() const noexcept;

Returns: true if the pathname in the generic format is empty, otherwise false.

bool has_root_path() const;

Returns: !root_path().empty().

bool has_root_name() const;

Returns: !root_name().empty().
bool has_root_directory() const;
  Returns: !root_directory().empty().

bool has_relative_path() const;
  Returns: !relative_path().empty().

bool has_parent_path() const;
  Returns: !parent_path().empty().

bool has_filename() const;
  Returns: !filename().empty().

bool has_stem() const;
  Returns: !stem().empty().

bool has_extension() const;
  Returns: !extension().empty().

bool is_absolute() const;
  Returns: true if the pathname in the native format contains an absolute path (29.11.7), otherwise false.

  [Example: path("/").is_absolute() is true for POSIX-based operating systems, and false for Windows-based operating systems. — end example]

bool is_relative() const;
  Returns: !is_absolute().

29.11.7.4.11 Generation

path lexically_normal() const;
  Returns: A path whose pathname in the generic format is the normal form (29.11.7.1) of the pathname in the
  generic format of *this.

  [Example:
    assert(path("foo/./bar/..").lexically_normal() == "foo/");
    assert(path("foo/../../../bar/..").lexically_normal() == "foo/");
  ]

  The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be
  backslashes rather than slashes, but that does not affect path equality. — end example]

path lexically_relative(const path& base) const;
  Effects: If:
    3.1 root_name() != base.root_name() is true, or
    3.2 is_absolute() != base.is_absolute() is true, or
    3.3 !has_root_directory() && base.has_root_directory() is true, or
    3.4 any filename in relative_path() or base.relative_path() can be interpreted as a root-name,
    returns path(). [Note: On a POSIX implementation, no filename in a relative-path is acceptable as a root-name.
    — end note] Determines the first mismatched element of *this and base as if by:
    auto [a, b] = mismatch(begin(), end(), base.begin(), base.end());

    Then,
    3.5 if a == end() and b == base.end(), returns path("."); otherwise
    3.6 let n be the number of filename elements in [b, base.end()) that are not dot or dot-dot or empty,
      minus the number that are dot-dot. If n<0, returns path(); otherwise
    3.7 if n == 0 and (a == end() || a->empty()), returns path("."); otherwise
    3.8 returns an object of class path that is default-constructed, followed by
    3.8.1 application of operator/=(path("..")) n times, and then

§ 29.11.7.4.11 1425
application of operator/= for each element in [a, end()).

Returns: *this made relative to base. Does not resolve (29.11.7) symlinks. Does not first normalize (29.11.7) *this or base.

[Example:
  assert(path("/a/d").lexically_relative("/a/b/c") == "../../d");
  assert(path("/a/b/c").lexically_relative("/a/d") == "./b/c");
  assert(path("a/b/c").lexically_relative("a") == "./b/c");
  assert(path("a/b/c").lexically_relative("a/b/c/x/y") == "./../a/b");
]
The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be backslashes rather than slashes, but that does not affect path equality. — end example]

[Note: If symlink following semantics are desired, use the operational function relative(). — end note]

path lexically_proximate(const path& base) const;

Returns: If the value of lexically_relative(base) is not an empty path, return it. Otherwise return *this.

[Note: If normalization (29.11.7) is needed to ensure consistent matching of elements, apply lexically_normal() to *this, base, or both. — end note]

29.11.7.5 Iterators

Path iterators iterate over the elements of the pathname in the generic format (29.11.7.1).

A path::iterator is a constant iterator meeting all the requirements of a bidirectional iterator (23.3.5.5) except that, for dereferenceable iterators a and b of type path::iterator with a == b, there is no requirement that *a and *b are bound to the same object. Its value_type is path.

Calling any non-const member function of a path object invalidates all iterators referring to elements of that object.

For the elements of the pathname in the generic format, the forward traversal order is as follows:

— The root-name element, if present.
— The root-directory element, if present. [Note: The generic format is required to ensure lexicographical comparison works correctly. — end note]
— Each successive filename element, if present.
— An empty element, if a trailing non-root directory-separator is present.

The backward traversal order is the reverse of forward traversal.

  iterator begin() const; Returns: An iterator for the first present element in the traversal list above. If no elements are present, the end iterator.

  iterator end() const; Returns: The end iterator.

29.11.7.6 Inserter and extractor

template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const path& p);

Effects: Equivalent to os << quoted(p.string<charT, traits>()) . [Note: The quoted function is described in 29.7.8. — end note]

Returns: os.
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, path& p);

3 Effects: Equivalent to:
  basic_string<charT, traits> tmp;
  is >> quoted(tmp);
  p = tmp;
4 Returns: is.

29.11.7.7 Non-member functions

void swap(path& lhs, path& rhs) noexcept;

1 Effects: Equivalent to lhs.swap(rhs).

size_t hash_value(const path& p) noexcept;

2 Returns: A hash value for the path p. If for two paths, p1 == p2 then hash_value(p1) == hash_value(p2).

friend bool operator==(const path& lhs, const path& rhs) noexcept;

3 Returns: lhs.compare(rhs) == 0.

Note: Path equality and path equivalence have different semantics.
(4.1) Equality is determined by the path non-member operator==, which considers the two paths' lexical representations only. [Example: path("foo") == "bar" is never true. —end example]
(4.2) Equivalence is determined by the equivalent() non-member function, which determines if two paths resolve (29.11.7) to the same file system entity. [Example: equivalent("foo", "bar") will be true when both paths resolve to the same file. —end example]

Programmers wishing to determine if two paths are "the same" must decide if "the same" means "the same representation" or "resolve to the same actual file", and choose the appropriate function accordingly. —end note

friend strong_ordering operator<=>(const path& lhs, const path& rhs) noexcept;

5 Returns: lhs.compare(rhs) <=> 0.

friend path operator/(const path& lhs, const path& rhs);

6 Effects: Equivalent to: return path(lhs) /= rhs;

29.11.8 Class filesystem_error

namespace std::filesystem {
  class filesystem_error : public system_error {
  public:
    filesystem_error(const string& what_arg, error_code ec);
    filesystem_error(const string& what_arg, const path& p1, error_code ec);
    filesystem_error(const string& what_arg, const path& p1, const path& p2, error_code ec);
    
    const path& path1() const noexcept;
    const path& path2() const noexcept;
   .const char* what() const noexcept override;
  };
}

1 The class filesystem_error defines the type of objects thrown as exceptions to report file system errors from functions described in subclause 29.11.

29.11.8.1 Members

1 Constructors are provided that store zero, one, or two paths associated with an error.

filesystem_error(const string& what_arg, error_code ec);
- code() == ec,
- path1().empty() == true, and
- string_view(what()).find(what_arg.c_str()) != string_view::npos.

filesystem_error(const string& what_arg, const path& p1, error_code ec);

Postconditions:
- code() == ec,
- path1() returns a reference to the stored copy of p1, and
- string_view(what()).find(what_arg.c_str()) != string_view::npos.

filesystem_error(const string& what_arg, const path& p1, const path& p2, error_code ec);

Postconditions:
- code() == ec,
- path1() returns a reference to the stored copy of p1,
- path2() returns a reference to the stored copy of p2, and
- string_view(what()).find(what_arg.c_str()) != string_view::npos.

const path& path1() const noexcept;
Returns: A reference to the copy of p1 stored by the constructor, or, if none, an empty path.

const path& path2() const noexcept;
Returns: A reference to the copy of p2 stored by the constructor, or, if none, an empty path.

const char* what() const noexcept override;
Returns: An /n.sc/t.sc/b.sc/s.sc that incorporates the what_arg argument supplied to the constructor. The exact format is unspecified. Implementations should include the system_error::what() string and the pathnames of path1 and path2 in the native format in the returned string.

29.11.9 Enumerations

29.11.9.1 Enum path::format
This enum specifies constants used to identify the format of the character sequence, with the meanings listed in Table 128.

Table 128: Enum path::format

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>native_format</td>
<td>The native pathname format.</td>
</tr>
<tr>
<td>generic_format</td>
<td>The generic pathname format.</td>
</tr>
<tr>
<td>auto_format</td>
<td>The interpretation of the format of the character sequence is</td>

<tr>
<td></td>
<td>implementation-defined. The implementation may inspect the content of</td>
</tr>
<tr>
<td></td>
<td>the character sequence to determine the format. [Note: For POSIX-based</td>
</tr>
<tr>
<td></td>
<td>systems, native and generic formats are equivalent and the character</td>
</tr>
<tr>
<td></td>
<td>sequence should always be interpreted in the same way. — end note]</td>
</tr>
</tbody>
</table>

29.11.9.2 Enum class file_type
This enum class specifies constants used to identify file types, with the meanings listed in Table 129. The values of the constants are distinct.

29.11.9.3 Enum class copy_options
The enum class type copy_options is a bitmask type (16.4.2.2.4) that specifies bitmask constants used to control the semantics of copy operations. The constants are specified in option groups with the meanings listed in Table 130.
Table 129: Enum class file_type  

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>The type of the file has not been determined or an error occurred while trying to determine the type.</td>
</tr>
<tr>
<td>not_found</td>
<td>Pseudo-type indicating the file was not found. [Note: The file not being found is not considered an error while determining the type of a file. — end note]</td>
</tr>
<tr>
<td>regular</td>
<td>Regular file</td>
</tr>
<tr>
<td>directory</td>
<td>Directory file</td>
</tr>
<tr>
<td>symlink</td>
<td>Symbolic link file</td>
</tr>
<tr>
<td>block</td>
<td>Block special file</td>
</tr>
<tr>
<td>character</td>
<td>Character special file</td>
</tr>
<tr>
<td>fifo</td>
<td>FIFO or pipe file</td>
</tr>
<tr>
<td>socket</td>
<td>Socket file</td>
</tr>
<tr>
<td>implementation-defined</td>
<td>Implementations that support file systems having file types in addition to the above file_type types shall supply implementation-defined file_type constants to separately identify each of those additional file types</td>
</tr>
<tr>
<td>unknown</td>
<td>The file exists but the type could not be determined</td>
</tr>
</tbody>
</table>

The constant none represents the empty bitmask, and is shown in each option group for purposes of exposition; implementations shall provide only a single definition. Every other constant in the table represents a distinct bitmask element.

Table 130: Enum class copy_options

</tbody>
</table>

29.11.9.5 Enum class perm_options

The enum class type perm_options is a bitmask type (16.4.2.2.4) that specifies bitmask constants used to control the semantics of permissions operations, with the meanings listed in Table 132. The bitmask constants are bitmask elements. In Table 132 perm denotes a value of type perms passed to permissions.

Table 132: Enum class perm_options

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>remove</td>
<td>permissions shall replace the file’s permission bits with the bitwise AND of the complement of perm and the file’s current permission bits.</td>
</tr>
<tr>
<td>nofollow</td>
<td>permissions shall change the permissions of a symbolic link itself rather than the permissions of the file the link resolves to.</td>
</tr>
</tbody>
</table>

29.11.9.6 Enum class directory_options

The enum class type directory_options is a bitmask type (16.4.2.2.4) that specifies bitmask constants used to identify directory traversal options, with the meanings listed in Table 133. The constant none represents the empty bitmask; every other constant in the table represents a distinct bitmask element.

29.11.10 Class file_status

namespace std::filesystem {
    class file_status {
        public:
            // 29.11.10.1, constructors and destructor

§ 29.11.10
Table 133: Enum class directory_options [tab:fs.enum.dir.opts]

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default) Skip directory symlinks, permission denied is an error.</td>
</tr>
<tr>
<td>follow_directory_symlink</td>
<td>Follow rather than skip directory symlinks.</td>
</tr>
<tr>
<td>skip_permission_denied</td>
<td>Skip directories that would otherwise result in permission denied.</td>
</tr>
</tbody>
</table>

```cpp
file_status() noexcept : file_status(file_type::none) {}
explicit file_status(file_type ft, 
    perms prms = perms::unknown) noexcept;
file_status(const file_status&) noexcept = default;
file_status(file_status&&) noexcept = default;
~file_status();
```

```cpp
// assignments
file_status& operator=(const file_status&) noexcept = default;
file_status& operator=(file_status&&) noexcept = default;
```

```cpp
// 29.11.10.2, observers
file_type type() const noexcept;
perms permissions() const noexcept;
```

```cpp
friend bool operator==(const file_status& lhs, const file_status& rhs) noexcept
{ return lhs.type() == rhs.type() && lhs.permissions() == rhs.permissions(); }
};
```

1 An object of type file_status stores information about the type and permissions of a file.

## 29.11.10.1 Constructors [fs.file.status.cons]

```cpp
explicit file_status(file_type ft, perms prms = perms::unknown) noexcept;
```

1 Postconditions: type() == ft and permissions() == prms.

## 29.11.10.2 Observers [fs.file.status.obs]

```cpp
file_type type() const noexcept;
perms permissions() const noexcept;
```

1 Returns: The value of type() specified by the postconditions of the most recent call to a constructor, operator=, or type(file_type) function.

## 29.11.10.3 Modifiers [fs.file.status.mods]

```cpp
void type(file_type ft) noexcept;
```

1 Postconditions: type() == ft.

```cpp
void permissions(perms prms) noexcept;
```

2 Postconditions: permissions() == prms.
29.11.11 Class directory_entry

namespace std::filesystem {
    class directory_entry {
    public:
        // 29.11.11.1, constructors and destructor

        file_status symlink_status(error_code& ec) const noexcept;
        bool operator==(const directory_entry& rhs) const noexcept;
        strong_ordering operator<=>(const directory_entry& rhs) const noexcept;
    };

private:
    filesystem::path pathobject; // exposition only
    friend class directory_iterator; // exposition only
};

§ 29.11.11 1432
A directory_entry object stores a path object and may store additional objects for file attributes such as hard link count, status, symlink status, file size, and last write time.

Implementations should store such additional file attributes during directory iteration if their values are available and storing the values would allow the implementation to eliminate file system accesses by directory_entry observer functions (29.11.14). Such stored file attribute values are said to be cached.

[Note: For purposes of exposition, class directory_iterator (29.11.12) is shown above as a friend of class directory_entry. Friendships allows the directory_iterator implementation to cache already available attribute values directly into a directory_entry object without the cost of an unneeded call to refresh(). — end note]

[Example:
  using namespace std::filesystem;
  // use possibly cached last write time to minimize disk accesses
  for (auto&& x : directory_iterator("."))
  {
    std::cout << x.path() << " " << x.last_write_time() << std::endl;
  }
  // call refresh() to refresh a stale cache
  for (auto&& x : directory_iterator("."))
  {
    lengthy_function(x.path()); // cache becomes stale
    x.refresh();
    std::cout << x.path() << " " << x.last_write_time() << std::endl;
  }

  On implementations that do not cache the last write time, both loops will result in a potentially expensive call to the std::filesystem::last_write_time function. On implementations that do cache the last write time, the first loop will use the cached value and so will not result in a potentially expensive call to the std::filesystem::last_write_time function. The code is portable to any implementation, regardless of whether or not it employs caching. — end example]

### 29.11.11.1 Constructors

[fs.dir.entry.cons]

explicit directory_entry(const filesystem::path& p);
directory_entry(const filesystem::path& p, error_code& ec);

Effects: Calls refresh() or refresh(ec), respectively.

Postconditions: path() == p if no error occurs, otherwise path() == filesystem::path().

Throws: As specified in 29.11.6.

### 29.11.11.2 Modifiers

[fs.dir.entry.mods]

void assign(const filesystem::path& p);
void assign(const filesystem::path& p, error_code& ec);

Effects: Equivalent to pathobject = p, then refresh() or refresh(ec), respectively. If an error occurs, the values of any cached attributes are unspecified.

Throws: As specified in 29.11.6.

void replace_filename(const filesystem::path& p);
void replace_filename(const filesystem::path& p, error_code& ec);

Effects: Equivalent to pathobject.replace_filename(p), then refresh() or refresh(ec), respectively. If an error occurs, the values of any cached attributes are unspecified.

Throws: As specified in 29.11.6.

void refresh();
void refresh(error_code& ec) noexcept;

Effects: Stores the current values of any cached attributes of the file p resolves to. If an error occurs, an error is reported (29.11.6) and the values of any cached attributes are unspecified.

§ 29.11.3
bool is_symlink(error_code& ec) const noexcept;

Returns: is_symlink(this->symlink_status()) or is_symlink(this->symlink_status(ec)), respectively.

Throws: As specified in 29.11.6.

uintmax_t file_size() const;
uintmax_t file_size(error_code& ec) const noexcept;

Returns: If cached, the file size attribute value. Otherwise, file_size(path()) or file_size(path(), ec), respectively.

Throws: As specified in 29.11.6.

uintmax_t hard_link_count() const;
uintmax_t hard_link_count(error_code& ec) const noexcept;

Returns: If cached, the hard link count attribute value. Otherwise, hard_link_count(path()) or hard_link_count(path(), ec), respectively.

Throws: As specified in 29.11.6.

file_time_type last_write_time() const;
file_time_type last_write_time(error_code& ec) const noexcept;

Returns: If cached, the last write time attribute value. Otherwise, last_write_time(path()) or last_write_time(path(), ec), respectively.

Throws: As specified in 29.11.6.

file_status status() const;
file_status status(error_code& ec) const noexcept;

Returns: If cached, the status attribute value. Otherwise, status(path()) or status(path(), ec), respectively.

Throws: As specified in 29.11.6.

file_status symlink_status() const;
file_status symlink_status(error_code& ec) const noexcept;

Returns: If cached, the symlink status attribute value. Otherwise, symlink_status(path()) or symlink_status(path(), ec), respectively.

Throws: As specified in 29.11.6.

bool operator==(const directory_entry& rhs) const noexcept;

Returns: pathobject == rhs.pathobject.

strong_ordering operator<=>(const directory_entry& rhs) const noexcept;

Returns: pathobject <=> rhs.pathobject.

29.11.12 Class directory_iterator

An object of type directory_iterator provides an iterator for a sequence of directory_entry elements representing the path and any cached attribute values (29.11.11) for each file in a directory or in an implementation-defined directory-like file type. [Note: For iteration into sub-directories, see class recursive_directory_iterator (29.11.13). — end note]

namespace std::filesystem {
    class directory_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = directory_entry;
        using difference_type = ptrdiff_t;
        using pointer = const directory_entry*;
        using reference = const directory_entry&;

        // 29.11.12.1, member functions
        directory_iterator() noexcept;
    }
explicit directory_iterator(const path& p);
directory_iterator(const path& p, directory_options options);
directory_iterator(const path& p, error_code& ec);
directory_iterator(const path& p, directory_options options, error_code& ec);
directory_iterator(const directory_iterator& rhs);
directory_iterator(directory_iterator&& rhs) noexcept;
~directory_iterator();
directory_iterator& operator=(const directory_iterator& rhs);
directory_iterator& operator=(directory_iterator&& rhs) noexcept;
const directory_entry& operator*() const;
const directory_entry* operator->() const;
directory_iterator& operator++();
increment(error_code& ec);

// other members as required by 23.3.5.2, input iterators
};

directory_iterator meets the Cpp17InputIterator requirements (23.3.5.2).

If an iterator of type directory_iterator reports an error or is advanced past the last directory element, that iterator shall become equal to the end iterator value. The directory_iterator default constructor shall create an iterator equal to the end iterator value, and this shall be the only valid iterator for the end condition.

The end iterator is not dereferenceable.

Two end iterators are always equal. An end iterator shall not be equal to a non-end iterator.

The result of calling the path() member of the directory_entry object obtained by dereferencing a directory_iterator is a reference to a path object composed of the directory argument from which the iterator was constructed with filename of the directory entry appended as if by operator/=. Directory iteration shall not yield directory entries for the current (dot) and parent (dot-dot) directories.

The order of directory entries obtained by dereferencing successive increments of a directory_iterator is unspecified.

Constructors and non-const directory_iterator member functions store the values of any cached attributes (29.11.11) in the directory_entry element returned by operator*(). directory_iterator member functions shall not directly or indirectly call any directory_entry refresh function. [Note: The exact mechanism for storing cached attribute values is not exposed to users. For exposition, class directory_iterator is shown in 29.11.11 as a friend of class directory_entry. — end note]

[Note: Programs performing directory iteration may wish to test if the path obtained by dereferencing a directory iterator actually exists. It could be a symbolic link to a non-existent file. Programs recursively walking directory trees for purposes of removing and renaming entries may wish to avoid following symbolic links. — end note]

[Note: If a file is removed from or added to a directory after the construction of a directory_iterator for the directory, it is unspecified whether or not subsequently incrementing the iterator will ever result in an iterator referencing the removed or added directory entry. See POSIX readdir_r. — end note]

29.11.12.1 Members [fs.dir.itr.members]
directory_iterator() noexcept;

explicit directory_iterator(const path& p);
directory_iterator(const path& p, directory_options options);
directory_iterator(const path& p, error_code& ec);
directory_iterator(const path& p, directory_options options, error_code& ec);

Effects: For the directory that p resolves to, constructs an iterator for the first element in a sequence of directory_entry elements representing the files in the directory, if any; otherwise the end iterator. However, if

(options & directory_options::skip_permission_denied) != directory_options::none
and construction encounters an error indicating that permission to access p is denied, constructs the end iterator and does not report an error.

3 Throws: As specified in 29.11.6.

4 [Note: To iterate over the current directory, use directory_iterator(".") rather than directory_iterator(""). — end note]

directory_iterator(const directory_iterator& rhs);
directory_iterator(directory_iterator&& rhs) noexcept;

5 Postconditions: *this has the original value of rhs.

directory_iterator& operator=(const directory_iterator& rhs);
directory_iterator& operator=(directory_iterator&& rhs) noexcept;

6 Effects: If *this and rhs are the same object, the member has no effect.

7 Postconditions: *this has the original value of rhs.

8 Returns: *this.

directory_iterator& operator++();
directory_iterator& increment(error_code& ec);

9 Effects: As specified for the prefix increment operation of Input iterators (23.3.5.2).

10 Returns: *this.

11 Throws: As specified in 29.11.6.

29.11.12.2 Non-member functions

These functions enable range access for directory_iterator.

directory_iterator begin(directory_iterator iter) noexcept;

2 Returns: iter.

directory_iterator end(const directory_iterator&) noexcept;

3 Returns: directory_iterator().

29.11.13 Class recursive_directory_iterator

An object of type recursive_directory_iterator provides an iterator for a sequence of directory_entry elements representing the files in a directory or in an implementation-defined directory-like file type, and its sub-directories.

```cpp
namespace std::filesystem {
    class recursive_directory_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = directory_entry;
        using difference_type = ptrdiff_t;
        using pointer = const directory_entry*;
        using reference = const directory_entry&;

        // 29.11.13.1, constructors and destructor
        recursive_directory_iterator() noexcept;
        explicit recursive_directory_iterator(const path& p);
        recursive_directory_iterator(const path& p, directory_options options);
        recursive_directory_iterator(const path& p, directory_options options,
                                      error_code& ec);
        recursive_directory_iterator(const path& p, error_code& ec);
        recursive_directory_iterator(const recursive_directory_iterator& rhs);
        recursive_directory_iterator(recursive_directory_iterator&& rhs) noexcept;
        "recursive_directory_iterator();

        // 29.11.13.1, observers
        directory_options options() const;
        int depth() const;
    };
```
bool recursion_pending() const;

const directory_entry& operator*() const;
const directory_entry* operator->() const;

// 29.11.13.1, modifiers
recursive_directory_iterator&
    operator=(const recursive_directory_iterator& rhs);
recursive_directory_iterator&
    operator=(recursive_directory_iterator&& rhs) noexcept;

recursive_directory_iterator& operator++();
recursive_directory_iterator& increment(error_code& ec);

void pop();
void pop(error_code& ec);
void disable_recursion_pending();

// other members as required by 23.3.5.2, input iterators

Calling options, depth, recursion_pending, pop or disable_recursion_pending on an iterator that is not dereferenceable results in undefined behavior.

The behavior of a recursive_directory_iterator is the same as a directory_iterator unless otherwise specified.

[Note: If the directory structure being iterated over contains cycles then the end iterator may be unreachable. — end note]

29.11.13.1 Members [fs.rec.dir.itr.members]

recursive_directory_iterator() noexcept;

Effects: Constructs the end iterator.

explicit recursive_directory_iterator(const path& p);
recursive_directory_iterator(const path& p, directory_options options);
recursive_directory_iterator(const path& p, directory_options options, error_code& ec);
recursive_directory_iterator(const path& p, error_code& ec);

Effects: Constructs an iterator representing the first entry in the directory to which p resolves, if any; otherwise, the end iterator. However, if

(options & directory_options::skip_permission_denied) != directory_options::none

and construction encounters an error indicating that permission to access p is denied, constructs the end iterator and does not report an error.

Postconditions: options() == options for the signatures with a directory_options argument, otherwise options() == directory_options::none.

Throws: As specified in 29.11.6.

[Note: To iterate over the current directory, use recursive_directory_iterator("").] — end note]

[Note: By default, recursive_directory_iterator does not follow directory symlinks. To follow directory

symlinks, specify options as directory_options::follow_directory_symlink. — end note]

recursive_directory_iterator(const recursive_directory_iterator& rhs);

Postconditions:

(7.1) options() == rhs.options()
(7.2) depth() == rhs.depth()
(7.3) recursion_pending() == rhs.recursion_pending()
recursive_directory_iterator(recursive_directory_iterator&& rhs) noexcept;

Postconditions: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

recursive_directory_iterator& operator=(const recursive_directory_iterator& rhs);

Effects: If *this and rhs are the same object, the member has no effect.

Postconditions:

(10.1) options() == rhs.options()

(10.2) depth() == rhs.depth()

(10.3) recursion_pending() == rhs.recursion_pending()

Returns: *this.

recursive_directory_iterator& operator=(recursive_directory_iterator&& rhs) noexcept;

Effects: If *this and rhs are the same object, the member has no effect.

Postconditions: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

Returns: *this.

directory_options options() const;

Returns: The value of the argument passed to the constructor for the options parameter, if present, otherwise directory_options::none.

Throws: Nothing.

int depth() const;

Returns: The current depth of the directory tree being traversed. [Note: The initial directory is depth 0, its immediate subdirectories are depth 1, and so forth. — end note]

Throws: Nothing.

bool recursion_pending() const;

Returns: true if disable_recursion_pending() has not been called subsequent to the prior construction or increment operation, otherwise false.

Throws: Nothing.

recursive_directory_iterator& operator++();
recursive_directory_iterator& increment(error_code& ec);

Effects: As specified for the prefix increment operation of Input iterators (23.5.2), except that:

(21.1) If there are no more entries at the current depth, then if depth() != 0 iteration over the parent directory resumes; otherwise *this = recursive_directory_iterator().

(21.2) Otherwise if

recursion_pending() && is_directory((*this)->status()) &&
(is_symlink((*this)->symlink_status()) ||
(options() & directory_options::follow_directory_symlink) != directory_options::none)

then either directory (*this)->path() is recursively iterated into or, if

(options() & directory_options::skip_permission_denied) != directory_options::none

and an error occurs indicating that permission to access directory (*this)->path() is denied, then directory (*this)->path() is treated as an empty directory and no error is reported.

Returns: *this.

Throws: As specified in 29.11.6.

void pop();
Effects: If depth() == 0, set *this to recursive_directory_iterator(). Otherwise, cease iteration of the directory currently being iterated over, and continue iteration over the parent directory.

Throw: As specified in 29.11.6.

Remarks: Any copies of the previous value of *this are no longer required to be dereferenceable nor to be in the domain of ==.

void disable_recursion_pending();

Postconditions: recursion_pending() == false.

[Note: disable_recursion_pending() is used to prevent unwanted recursion into a directory. — end note]

29.11.13.2 Non-member functions

These functions enable use of recursive_directory_iterator with range-based for statements.

recursive_directory_iterator begin(recursive_directory_iterator iter) noexcept;

Returns: iter.

recursive_directory_iterator end(const recursive_directory_iterator&) noexcept;

Returns: recursive_directory_iterator().

29.11.14 Filesystem operation functions

Filesystem operation functions query or modify files, including directories, in external storage.

[Note: Because hardware failures, network failures, file system races (29.11.2.3), and many other kinds of errors occur frequently in file system operations, users should be aware that any filesystem operation function, no matter how apparently innocuous, may encounter an error; see 29.11.6. — end note]

29.11.14.1 Absolute

path absolute(const path& p);

path absolute(const path& p, error_code& ec);

Effects: Composes an absolute path referencing the same file system location as p according to the operating system (29.11.2.2).

Returns: The composed path. The signature with argument ec returns path() if an error occurs.

[Note: For the returned path, rp, rp.is_absolute() is true unless an error occurs. — end note]

Throws: As specified in 29.11.6.

[Note: To resolve symlinks, or perform other sanitization which might require queries to secondary storage, such as hard disks, consider canonical (29.11.14.2). — end note]

[Note: Implementations are strongly encouraged to not query secondary storage, and not consider !exists(p) an error. — end note]

[Example: For POSIX-based operating systems, absolute(p) is simply current_path() / p. For Windows-based operating systems, absolute might have the same semantics as GetFullPathNameW. — end example]

29.11.14.2 Canonical

path canonical(const path& p);

path canonical(const path& p, error_code& ec);

Effects: Converts p to an absolute path that has no symbolic link, dot, or dot-dot elements in its pathname in the generic format.

Returns: A path that refers to the same file system object as absolute(p). The signature with argument ec returns path() if an error occurs.

Throws: As specified in 29.11.6.

Remarks: !exists(p) is an error.
29.11.4.3 Copy

void copy(const path& from, const path& to);

Effects: Equivalent to copy(from, to, copy_options::none).

Effects: Equivalent to copy(from, to, copy_options::none, ec).

Effects: Before the first use of f and t:

- If
  
  (options & copy_options::create_symlinks) != copy_options::none ||
  
  (options & copy_options::skip_symlinks) != copy_options::none

  then auto f = symlink_status(from) and if needed auto t = symlink_status(to).

- Otherwise, if
  
  (options & copy_options::copy_symlinks) != copy_options::none

  then auto f = symlink_status(from) and if needed auto t = status(to).

- Otherwise, auto f = status(from) and if needed auto t = status(to).

Effects are then as follows:

- If f.type() or t.type() is an implementation-defined file type (29.11.9.2), then the effects are implementation-defined.

- Otherwise, an error is reported as specified in 29.11.6 if:

  - exists(f) is false, or
  
  - equivalent(from, to) is true, or
  
  - is_other(f) || is_other(t) is true, or
  
  - is_directory(f) && is_regular_file(t) is true.

- Otherwise, if is_symlink(f), then:

  - If (options & copy_options::skip_symlinks) != copy_options::none then return.

  - Otherwise if

    !exists(t) && (options & copy_options::copy_symlinks) != copy_options::none

    then copy_symlink(from, to).

- Otherwise, if is_regular_file(f), then:

  - If (options & copy_options::directories_only) != copy_options::none, then return.

  - Otherwise, if (options & copy_options::create_symlinks) != copy_options::none, then create a symbolic link to the source file.

  - Otherwise, if (options & copy_options::create_hard_links) != copy_options::none, then create a hard link to the source file.

  - Otherwise, if is_directory(t), then copy_file(from, to/from.filename(), options).

  - Otherwise, copy_file(from, to, options).

- Otherwise, if

  is_directory(f) &&
  
  (options & copy_options::create_symlinks) != copy_options::none

  then report an error with an error_code argument equal to make_error_code(errc::is_a_directory).

- Otherwise, if
is_directory(f) &&
(\( \text{options} \& \text{copy_options::recursive} \) != \text{copy_options::none} ||
\( \text{options} == \text{copy_options::none} \))

then:

\(\text{(4.9.1)}\) If \( \exists(t) \) is false, then \text{create_directory}(to, from).

\(\text{(4.9.2)}\) Then, iterate over the files in from, as if by

\[
\text{for} \ (\text{const directory_entry} \& \ x : \text{directory_iterator(from)})
\]
\[
\text{copy(x.path(), to/x.path().filename(),}
\phantom{\text{options | copy_options::in-recursive-copy;}}
\]

where \text{in-recursive-copy} is a bitmask element of \text{copy_options} that is not one of the elements
in \text{29.11.9.3}.

\(\text{(4.10)}\) Otherwise, for the signature with argument \text{ec}, \text{ec.clear()}.

\(\text{(4.11)}\) Otherwise, no effects.

**Throws:** As specified in \text{29.11.6}.

**Remarks:** For the signature with argument \text{ec}, any library functions called by the implementation shall have
an \text{error_code} argument if applicable.

**Example:** Given this directory structure:

```
/dir1
  file1
  file2
  dir2
    file3
```

Calling \text{copy("/dir1", "/dir3")} would result in:

```
/dir1
  file1
  file2
  dir2
    file3
/dir3
  file1
  file2
```

Alternatively, calling \text{copy("/dir1", "/dir3", \text{copy_options::recursive}) would result in:

```
/dir1
  file1
  file2
  dir2
    file3
/dir3
  file1
  file2
  dir2
    file3
```

---

29.11.14.4 Copy file

\[
\text{bool copy_file(const path& from, const path& to);}
\]
\[
\text{bool copy_file(const path& from, const path& to, error_code& ec);}\
\]

1 **Returns:** \text{copy_file(from, to, \text{copy_options::none}) or}
\[ \text{copy_file(from, to, \text{copy_options::none, ec}), respectively.} \]

2 **Throws:** As specified in \text{29.11.6}.

\[
\text{bool copy_file(const path& from, const path& to, \text{copy_options options});}
\]
bool copy_file(const path& from, const path& to, copy_options options,
            error_code& ec);

Preconditions: At most one element from each option group (29.11.9.3) is set in options.

Effects: As follows:

(4.1) Report an error as specified in 29.11.6 if:
   - is_regular_file(from) is false, or
   - exists(to) is true and is_regular_file(to) is false, or
   - exists(to) is true and equivalent(from, to) is true, or
   - exists(to) is true and
     (options & (copy_options::skip_existing |
                  copy_options::overwrite_existing |
                  copy_options::update_existing)) == copy_options::none

(4.2) Otherwise, copy the contents and attributes of the file from resolves to, to the file to resolves to, if:
   - exists(to) is false, or
   - (options & copy_options::overwrite_existing) != copy_options::none, or
   - (options & copy_options::update_existing) != copy_options::none and from is more recent than to, determined as if by use of the last_write_time function (29.11.14.25).

(4.3) Otherwise, no effects.

Returns: true if the from file was copied, otherwise false. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

Complexity: At most one direct or indirect invocation of status(to).

29.11.14.5 Copy symlink

[fs.op.copy.symlink]

void copy_symlink(const path& existing_symlink, const path& new_symlink);
void copy_symlink(const path& existing_symlink, const path& new_symlink,
            error_code& ec) noexcept;

Effects: Equivalent to function (read_symlink(existing_symlink), new_symlink) or
function (read_symlink(existing_symlink, ec), new_symlink, ec), respectively, where in each
case function is create_symlink or create_directory_symlink as appropriate.

Throws: As specified in 29.11.6.

29.11.14.6 Create directories

[fs.op.create.directories]

bool create_directories(const path& p);
bool create_directories(const path& p, error_code& ec);

Effects: Calls create_directory() for each element of p that does not exist.

Returns: true if a new directory was created for the directory p resolves to, otherwise false.

Throws: As specified in 29.11.6.

Complexity: $O(n)$ where n is the number of elements of p.

29.11.14.7 Create directory

[fs.op.create.directory]

bool create_directory(const path& p);
bool create_directory(const path& p, error_code& ec) noexcept;

Effects: Creates the directory p resolves to, as if by POSIX mkdir with a second argument of static_cast<int>(perms::all). If mkdir fails because p resolves to an existing directory, no error is reported. Otherwise on failure an error is reported.

Returns: true if a new directory was created, otherwise false.

Throws: As specified in 29.11.6.
bool create_directory(const path& p, const path& existing_p);
bool create_directory(const path& p, const path& existing_p, error_code& ec) noexcept;

Effects: Creates the directory \( p \) resolves to, with attributes copied from directory \( \text{existing}_p \). The set of attributes copied is operating system dependent. If \text{mkdir} fails because \( p \) resolves to an existing directory, no error is reported. Otherwise on failure an error is reported. [Note: For POSIX-based operating systems, the attributes are those copied by native API \text{stat}(\text{existing}_p.\text{c_str}(), \&\text{attributes}_\text{stat}) followed by \text{mkdir}(p.\text{c_str}(), \text{attributes}_\text{stat}.\text{st_mode}). For Windows-based operating systems, the attributes are those copied by native API \text{CreateDirectoryExW}(\text{existing}_p.\text{c_str}(), p.\text{c_str}(), 0). — end note]

Returns: \( \text{true} \) if a new directory was created with attributes copied from directory \( \text{existing}_p \), otherwise \( \text{false} \).

Throws: As specified in 29.11.6.

29.11.14.8 Create directory symlink

void create_directory_symlink(const path& to, const path& new_symlink);
void create_directory_symlink(const path& to, const path& new_symlink, error_code& ec) noexcept;

Effects: Establishes the postcondition, as if by POSIX \text{symlink}().

Postconditions: \( \text{new}_\text{symlink} \) resolves to a symbolic link file that contains an unspecified representation of \( \text{to} \).

Throws: As specified in 29.11.6.

[Note: Some operating systems require symlink creation to identify that the link is to a directory. Portable code should use \text{create_directory_symlink()} to create directory symlinks rather than \text{create_symlink()} — end note]

[Note: Some operating systems do not support symbolic links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support symbolic links regardless of the operating system. — end note]

29.11.14.9 Create hard link

void create_hard_link(const path& to, const path& new_hard_link);
void create_hard_link(const path& to, const path& new_hard_link, error_code& ec) noexcept;

Effects: Establishes the postcondition, as if by POSIX \text{link}().

Postconditions:

(2.1) \( \text{exists}(\text{to}) \) \&\& \( \text{exists}(\text{new}_\text{hard}_\text{link}) \) \&\& \( \text{equivalent}(\text{to}, \text{new}_\text{hard}_\text{link}) \)

(2.2) The contents of the file or directory \( \text{to} \) resolves to are unchanged.

Throws: As specified in 29.11.6.

[Note: Some operating systems do not support hard links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support hard links regardless of the operating system. Some file systems limit the number of links per file. — end note]

29.11.14.10 Create symlink

void create_symlink(const path& to, const path& new_symlink);
void create_symlink(const path& to, const path& new_symlink, error_code& ec) noexcept;

Effects: Establishes the postcondition, as if by POSIX \text{symlink}().

Postconditions: \( \text{new}_\text{symlink} \) resolves to a symbolic link file that contains an unspecified representation of \( \text{to} \).

Throws: As specified in 29.11.6.

[Note: Some operating systems do not support symbolic links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support symbolic links regardless of the operating system. — end note]
29.11.14.11 Current path  

path current_path();
path current_path(error_code& ec);

1  Returns: The absolute path of the current working directory, whose pathname in the native format is obtained as if by POSIX `getcwd()`. The signature with argument `ec` returns `path()` if an error occurs.

2  Throws: As specified in 29.11.6.

3  Remarks: The current working directory is the directory, associated with the process, that is used as the starting location in pathname resolution for relative paths.

4  [Note: The `current_path()` name was chosen to emphasize that the returned value is a path, not just a single directory name. — end note]

5  [Note: The current path as returned by many operating systems is a dangerous global variable. It may be changed unexpectedly by third-party or system library functions, or by another thread. — end note]

void current_path(const path& p);
void current_path(const path& p, error_code& ec) noexcept;

6  Effects: Establishes the postcondition, as if by POSIX `chdir()`.

7  Postconditions: `equivalent(p, current_path())`.

8  Throws: As specified in 29.11.6.

9  [Note: The current path for many operating systems is a dangerous global state. It may be changed unexpectedly by a third-party or system library functions, or by another thread. — end note]

29.11.14.12 Equivalent  

bool equivalent(const path& p1, const path& p2);
bool equivalent(const path& p1, const path& p2, error_code& ec) noexcept;

1  Two paths are considered to resolve to the same file system entity if two candidate entities reside on the same device at the same location. [Note: On POSIX platforms, this is determined as if by the values of the POSIX `stat` class, obtained as if by `stat()` for the two paths, having equal `st_dev` values and equal `st_ino` values. — end note]

2  Returns: true, if `p1` and `p2` resolve to the same file system entity, otherwise false. The signature with argument `ec` returns false if an error occurs.

3  Throws: As specified in 29.11.6.

4  Remarks: `!exists(p1) || !exists(p2)` is an error.

29.11.14.13 Exists  

bool exists(file_status s) noexcept;

1  Returns: `status_known(s) && s.type() != file_type::not_found`.

bool exists(const path& p);
bool exists(const path& p, error_code& ec) noexcept;

2  Let `s` be a `file_status`, determined as if by `status(p)` or `status(p, ec)`, respectively.

3  Effects: The signature with argument `ec` calls `ec.clear()` if `status_known(s)`.

4  Returns: `exists(s)`.

5  Throws: As specified in 29.11.6.

29.11.14.14 File size  

```cpp
uintmax_t file_size(const path& p);
uintmax_t file_size(const path& p, error_code& ec) noexcept;
```

1  Effects: If `exists(p)` is false, an error is reported (29.11.6).

2  Returns:

(2.1)  — If `is_regular_file(p)`, the size in bytes of the file `p` resolves to, determined as if by the value of the POSIX `stat` class member `st_size` obtained as if by POSIX `stat()`.
— Otherwise, the result is implementation-defined.

The signature with argument \( ec \) returns \( \text{static
cast<uintmax_t>(-1)} \) if an error occurs.

**Throws:** As specified in 29.11.6.

**29.11.15 Hard link count**

\[
\text{uintmax_t hard_link_count(const path& p);} 
\text{uintmax_t hard_link_count(const path& p, error_code& ec) noexcept;}
\]

1. **Returns:** The number of hard links for \( p \). The signature with argument \( ec \) returns \( \text{static
cast<uintmax_t>(-1)} \) if an error occurs.
2. **Throws:** As specified in 29.11.6.

**29.11.16 Is block file**

\[
\text{bool is_block_file(file_status s) noexcept;}
\text{bool is_block_file(const path& p);} 
\text{bool is_block_file(const path& p, error_code& ec) noexcept;}
\]

1. **Returns:** \( s \text{.type()} == \text{file_type::block} \).
2. **Returns:** \( \text{is_block_file(status(p)) or is_block_file(status(p, ec))} \), respectively. The signature with argument \( ec \) returns \( \text{false} \) if an error occurs.
3. **Throws:** As specified in 29.11.6.

**29.11.17 Is character file**

\[
\text{bool is_character_file(file_status s) noexcept;}
\text{bool is_character_file(const path& p);} 
\text{bool is_character_file(const path& p, error_code& ec) noexcept;}
\]

1. **Returns:** \( s \text{.type()} == \text{file_type::character} \).
2. **Returns:** \( \text{is_character_file(status(p)) or is_character_file(status(p, ec))} \), respectively. The signature with argument \( ec \) returns \( \text{false} \) if an error occurs.
3. **Throws:** As specified in 29.11.6.

**29.11.18 Is directory**

\[
\text{bool is_directory(file_status s) noexcept;}
\text{bool is_directory(const path& p);} 
\text{bool is_directory(const path& p, error_code& ec) noexcept;}
\]

1. **Returns:** \( s \text{.type()} == \text{file_type::directory} \).
2. **Returns:** \( \text{is_directory(status(p)) or is_directory(status(p, ec))} \), respectively. The signature with argument \( ec \) returns \( \text{false} \) if an error occurs.
3. **Throws:** As specified in 29.11.6.

**29.11.19 Is empty**

\[
\text{bool is_empty(const path& p);} 
\text{bool is_empty(const path& p, error_code& ec);}
\]

1. **Effects:**
   1. **(1.1)** — Determine file_status s, as if by status(p) or status(p, ec), respectively.
   1. **(1.2)** — For the signature with argument ec, return false if an error occurred.
   1. **(1.3)** — Otherwise, if is_directory(s):
      1. **(1.3.1)** — Create a variable itr, as if by directory_iterator itr(p) or directory_iterator itr(p, ec), respectively.
      1. **(1.3.2)** — For the signature with argument ec, return false if an error occurred.
      1. **(1.3.3)** — Otherwise, return itr == directory_iterator().
— Otherwise:
  — Determine uintmax_t sz, as if by file_size(p) or file_size(p, ec), respectively.
  — For the signature with argument ec, return false if an error occurred.
— Otherwise, return sz == 0.

Throws: As specified in 29.11.6.

29.11.14.20 Is fifo

bool is_fifo(file_status s) noexcept;

Returns: s.type() == file_type::fifo.

bool is_fifo(const path& p);
bool is_fifo(const path& p, error_code& ec) noexcept;

Returns: is_fifo(status(p)) or is_fifo(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.21 Is other

bool is_other(file_status s) noexcept;

Returns: exists(s) && !is_regular_file(s) && !is_directory(s) && !is_symlink(s).

bool is_other(const path& p);
bool is_other(const path& p, error_code& ec) noexcept;

Returns: is_other(status(p)) or is_other(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.22 Is regular file

bool is_regular_file(file_status s) noexcept;

Returns: s.type() == file_type::regular.

bool is_regular_file(const path& p);

Returns: is_regular_file(status(p)).

Throws: filesystem_error if status(p) would throw filesystem_error.

bool is_regular_file(const path& p, error_code& ec) noexcept;

Effects: Sets ec as if by status(p, ec). [Note: file_type::none, file_type::not_found and file_type::unknown cases set ec to error values. To distinguish between cases, call the status function directly. — end note]

Returns: is_regular_file(status(p, ec)). Returns false if an error occurs.

29.11.14.23 Is socket

bool is_socket(file_status s) noexcept;

Returns: s.type() == file_type::socket.

bool is_socket(const path& p);
bool is_socket(const path& p, error_code& ec) noexcept;

Returns: is_socket(status(p)) or is_socket(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.24 Is symlink

bool is_symlink(file_status s) noexcept;

Returns: s.type() == file_type::symlink.
bool is_symlink(const path& p);
bool is_symlink(const path& p, error_code& ec) noexcept;

Returns: is_symlink(symlink_status(p)) or is_symlink(symlink_status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.25 Last write time

file_time_type last_write_time(const path& p);
file_time_type last_write_time(const path& p, error_code& ec) noexcept;

Returns: The time of last data modification of p, determined as if by the value of the POSIX stat class member st_mtime obtained as if by POSIX stat(). The signature with argument ec returns file_time_type::min() if an error occurs.

Throws: As specified in 29.11.6.

void last_write_time(const path& p, file_time_type new_time);
void last_write_time(const path& p, file_time_type new_time,
         error_code& ec) noexcept;

Effects: Sets the time of last data modification of the file resolved to by p to new_time, as if by POSIX futimens().

Throws: As specified in 29.11.6.

[Note: A postcondition of last_write_time(p) == new_time is not specified since it might not hold for file systems with coarse time granularity. — end note]

29.11.14.26 Permissions

void permissions(const path& p, perms prms, perm_options opts=perm_options::replace);
void permissions(const path& p, perms prms, error_code& ec) noexcept;
void permissions(const path& p, perms prms, perm_options opts, error_code& ec);

Preconditions: Exactly one of the perm_options constants replace, add, or remove is present in opts.

Effects: Applies the action specified by opts to the file p resolves to, or to file p itself if p is a symbolic link and perm_options::nofollow is set in opts. The action is applied as if by POSIX fchmodat().

[Note: Conceptually permissions are viewed as bits, but the actual implementation may use some other mechanism. — end note]

Throws: As specified in 29.11.6.

Remarks: The second signature behaves as if it had an additional parameter perm_options opts with an argument of perm_options::replace.

29.11.14.27 Proximate

path proximate(const path& p, error_code& ec);

Returns: proximate(p, current_path(), ec).

Throws: As specified in 29.11.6.

path proximate(const path& p, const path& base = current_path());
path proximate(const path& p, const path& base, error_code& ec);

Returns: For the first form:
weakly_canonical(p).lexically_proximate(weakly_canonical(base));
For the second form:
weakly_canonical(p, ec).lexically_proximate(weakly_canonical(base, ec));
or path() at the first error occurrence, if any.

Throws: As specified in 29.11.6.

§ 29.11.27
29.11.14.28 Read symlink

path read_symlink(const path& p);
path read_symlink(const path& p, error_code& ec);

1 Returns: If p resolves to a symbolic link, a path object containing the contents of that symbolic link. The signature with argument ec returns path() if an error occurs.

2 Throws: As specified in 29.11.6. [Note: It is an error if p does not resolve to a symbolic link. — end note]

29.11.14.29 Relative

path relative(const path& p, error_code& ec);

1 Returns: relative(p, current_path(), ec).

2 Throws: As specified in 29.11.6.

path relative(const path& p, const path& base = current_path());
path relative(const path& p, const path& base, error_code& ec);

3 Returns: For the first form:
weakly_canonical(p).lexically_relative(weakly_canonical(base));
For the second form:
weakly_canonical(p, ec).lexically_relative(weakly_canonical(base, ec));
or path() at the first error occurrence, if any.

4 Throws: As specified in 29.11.6.

29.11.14.30 Remove

bool remove(const path& p);
bool remove(const path& p, error_code& ec) noexcept;

1 Effects: If exists(symlink_status(p, ec)), the file p is removed as if by POSIX remove(). [Note: A symbolic link is itself removed, rather than the file it resolves to. — end note]

2 Postconditions: exists(symlink_status(p)) is false.

3 Returns: false if p did not exist, otherwise true. The signature with argument ec returns false if an error occurs.

4 Throws: As specified in 29.11.6.

29.11.14.31 Remove all

uintmax_t remove_all(const path& p);
uintmax_t remove_all(const path& p, error_code& ec);

1 Effects: Recursively deletes the contents of p if it exists, then deletes file p itself, as if by POSIX remove(). [Note: A symbolic link is itself removed, rather than the file it resolves to. — end note]

2 Postconditions: exists(symlink_status(p)) is false.

3 Returns: The number of files removed. The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.

4 Throws: As specified in 29.11.6.

29.11.14.32 Rename

void rename(const path& old_p, const path& new_p);
void rename(const path& old_p, const path& new_p, error_code& ec) noexcept;

1 Effects: Renames old_p to new_p, as if by POSIX rename().

[Note:
(1.1) — If old_p and new_p resolve to the same existing file, no action is taken.
(1.2) — Otherwise, the rename may include the following effects:
(1.2.1) — if new_p resolves to an existing non-directory file, new_p is removed; otherwise,
if new_p resolves to an existing directory, new_p is removed if empty on POSIX compliant operating systems but may be an error on other operating systems.

A symbolic link is itself renamed, rather than the file it resolves to. — end note

29.11.14.33  Resize file  

\[fs.ressize.file\]

```c
void resize_file(const path& p, uintmax_t new_size);
void resize_file(const path& p, uintmax_t new_size, error_code& ec) noexcept;
```

Effects: Causes the size that would be returned by `file_size(p)` to be equal to `new_size`, as if by POSIX `truncate()`. 

2  Throws: As specified in \ref{9.11.6}.

29.11.14.34  Space  

\[fs.space\]

```c
space_info space(const path& p);
space_info space(const path& p, error_code& ec) noexcept;
```

Returns: An object of type `space_info`. The value of the `space_info` object is determined as if by using POSIX `statvfs` to obtain a POSIX `struct statvfs`, and then multiplying its `f_blocks`, `f_bfree`, and `f_bavail` members by its `f_frsize` member, and assigning the results to the capacity, free, and available members respectively. Any members for which the value cannot be determined shall be set to \texttt{static_cast<uintmax_t>(-1)}. For the signature with argument `ec`, all members are set to \texttt{static_cast<uintmax_t>(-1)} if an error occurs. 

2  Throws: As specified in \ref{29.11.6}.

3  Remarks: The value of member `space_info::available` is operating system dependent. [Note: available may be less than `free`. — end note]

29.11.14.35  Status  

\[fs.status\]

```c
file_status status(const path& p);
```

Effects: As if:

```c
error_code ec;
file_status result = status(p, ec);
if (result.type() == file_type::none)
    throw filesystem_error(implementation-supplied-message, p, ec);
return result;
```

2  Returns: See above.

3  Throws: `filesystem_error`. [Note: result values of `file_status(file_type::not_found)` and `file_status(file_type::unknown)` are not considered failures and do not cause an exception to be thrown. — end note]

```c
file_status status(const path& p, error_code& ec) noexcept;
```

Effects: If possible, determines the attributes of the file `p` resolves to, as if by using POSIX `stat()` to obtain a POSIX `struct stat`. If, during attribute determination, the underlying file system API reports an error, sets `ec` to indicate the specific error reported. Otherwise, `ec.clear()`. [Note: This allows users to inspect the specifics of underlying API errors even when the value returned by `status()` is not `file_status(file_type::none)`. — end note]

Let `prms` denote the result of `(m & perms::mask)`, where `m` is determined as if by converting the `st_mode` member of the obtained `struct stat` to the type `perms`.

5  Returns:

6 (6.1)

- If `ec != error_code()`:

6 (6.1.1)

- If the specific error indicates that `p` cannot be resolved because some element of the path does not exist, returns `file_status(file_type::not_found)`. 

6 (6.1.2)

- Otherwise, if the specific error indicates that `p` can be resolved but the attributes cannot be determined, returns `file_status(file_type::unknown)`.

§ 29.11.14.35  1450
(6.1.3) Otherwise, returns file_status(file_type::none).

[Note: These semantics distinguish between p being known not to exist, p existing but not being able to determine its attributes, and there being an error that prevents even knowing if p exists. These distinctions are important to some use cases. — end note]

(6.2) Otherwise,

(6.2.1) If the attributes indicate a regular file, as if by POSIX S_ISREG, returns file_status(file_type::regular, prms). [Note: file_type::regular implies appropriate <fstream> operations would succeed, assuming no hardware, permission, access, or file system race errors. Lack of file_type::regular does not necessarily imply <fstream> operations would fail on a directory. — end note]

(6.2.2) Otherwise, if the attributes indicate a directory, as if by POSIX S_ISDIR, returns file_status(file_type::directory, prms). [Note: file_type::directory implies that calling directory_iterator(p) would succeed. — end note]

(6.2.3) Otherwise, if the attributes indicate a block special file, as if by POSIX S_ISBLK, returns file_status(file_type::block, prms).

(6.2.4) Otherwise, if the attributes indicate a character special file, as if by POSIX S_ISCHR, returns file_status(file_type::character, prms).

(6.2.5) Otherwise, if the attributes indicate a fifo or pipe file, as if by POSIX S_ISFIFO, returns file_status(file_type::fifo, prms).

(6.2.6) Otherwise, if the attributes indicate a socket, as if by POSIX S_ISSOCK, returns file_status(file_type::socket, prms).

(6.2.7) Otherwise, if the attributes indicate an implementation-defined file type (29.11.9.2), returns file_status(file_type::implementation-defined, prms).

(6.2.8) Otherwise, returns file_status(file_type::unknown, prms).

Remarks: If a symbolic link is encountered during pathname resolution, pathname resolution continues using the contents of the symbolic link.

29.11.14.36 Status known [fs.op.status.known]

bool status_known(file_status s) noexcept;

Returns: s.type() != file_type::unknown.

29.11.14.37 Symlink status [fs.op.symlink.status]

file_status symlink_status(const path& p);
file_status symlink_status(const path& p, error_code& ec) noexcept;

Effects: Same as status(), above, except that the attributes of p are determined as if by using POSIX lstat() to obtain a POSIX struct stat.

Let prms denote the result of (m & perms::mask), where m is determined as if by converting the st_mode member of the obtained struct stat to the type perms.

Returns: Same as status(), above, except that if the attributes indicate a symbolic link, as if by POSIX S_ISLNK, returns file_status(file_type::symlink, prms). The signature with argument ec returns file_status(file_type::none) if an error occurs.

Throws: As specified in 29.11.6.

Remarks: Pathname resolution terminates if p names a symbolic link.

29.11.14.38 Temporary directory path [fs.op.temp.dir.path]

path temp_directory_path();
path temp_directory_path(error_code& ec);

Let p be an unspecified directory path suitable for temporary files.

Effects: If exists(p) is false or is_directory(p) is false, an error is reported (29.11.6).

Returns: The path p. The signature with argument ec returns path() if an error occurs.
4. Throws: As specified in 29.11.6.

5. [Example: For POSIX-based operating systems, an implementation might return the path supplied by the first environment variable found in the list TMPDIR, TMP, TEMP, TEMPDIR, or if none of these are found, "/tmp". For Windows-based operating systems, an implementation might return the path reported by the Windows GetTempPath API function. — end example]

29.11.14.39 Weakly canonical

path weakly_canonical(const path& p);
path weakly_canonical(const path& p, error_code& ec);

Effects: Using status(p) or status(p, ec), respectively, to determine existence, return a path composed by operator/= from the result of calling canonical() with a path argument composed of the leading elements of p that exist, if any, followed by the elements of p that do not exist, if any. For the first form, canonical() is called without an error_code argument. For the second form, canonical() is called with ec as an error_code argument, and path() is returned at the first error occurrence, if any.

Postconditions: The returned path is in normal form (29.11.7.1).

Returns: p with symlinks resolved and the result normalized (29.11.7.1).

Throws: As specified in 29.11.6.

Remarks: Implementations should avoid unnecessary normalization such as when canonical has already been called on the entirety of p.

#define PRIxN see below
#define PRIxN see below

§ 29.12.2
The contents and meaning of the header `<cinttypes>` are the same as the C standard library header `<inttypes.h>`, with the following changes:

1. The header `<cinttypes>` includes the header `<cstdint>` (17.4.1) instead of `<stdint.h>`, and
2. if and only if the type `intmax_t` designates an extended integer type (6.8.1), the following function signatures are added:

   ```c
   intmax_t abs(intmax_t);
   imaxdiv_t div(intmax_t, intmax_t);
   ```

   which shall have the same semantics as the function signatures `intmax_t imaxabs(intmax_t)` and `imaxdiv_t imaxdiv(intmax_t, intmax_t)`, respectively.

30  Regular expressions library [re]

30.1  General [re.general]

1 This Clause describes components that C++ programs may use to perform operations involving regular expression matching and searching.

2 The following subclauses describe a basic regular expression class template and its traits that can handle char-like (21.1) template arguments, two specializations of this class template that handle sequences of char and wchar_t, a class template that holds the result of a regular expression match, a series of algorithms that allow a character sequence to be operated upon by a regular expression, and two iterator types for enumerating regular expression matches, as summarized in Table 134.

30.2  Definitions [re.def]

1 The following definitions shall apply to this Clause:

30.2.1  [defns.regex.collating.element]
collating element
a sequence of one or more characters within the current locale that collate as if they were a single character.

30.2.2  [defns.regex.finite.state.machine]
finite state machine
an unspecified data structure that is used to represent a regular expression, and which permits efficient matches against the regular expression to be obtained.

30.2.3  [defns.regex.format.specifier]
format specifier
a sequence of one or more characters that is to be replaced with some part of a regular expression match.

30.2.4  [defns.regex.matched]
matched
a sequence of zero or more characters is matched by a regular expression when the characters in the sequence correspond to a sequence of characters defined by the pattern.

30.2.5  [defns.regex.primary.equivalence.class]
primary equivalence class
a set of one or more characters which share the same primary sort key: that is the sort key weighting that depends only upon character shape, and not accents, case, or locale specific tailorings.
### 30.2.6 Regular expression

A pattern that selects specific strings from a set of character strings.

### 30.2.7 Sub-expression

A subset of a regular expression that has been marked by parenthesis.

### 30.3 Requirements

1. This subclause defines requirements on classes representing regular expression traits. [Note: The class template `regex_traits`, defined in 30.7, meets these requirements. —end note]

2. The class template `basic_regex`, defined in 30.8, needs a set of related types and functions to complete the definition of its semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by the `basic_regex` class template. This subclause defines the semantics of these members.

3. To specialize class template `basic_regex` for a character container `CharT` and its related regular expression traits class `Traits`, use `basic_regex<CharT, Traits>`.

4. In Table 135 `X` denotes a traits class defining types and functions for the character container type `charT`; `u` is an object of type `X`; `v` is an object of type `const X`; `p` is a value of type `const charT*`; `I1` and `I2` are input iterators (23.3.5.2); `F1` and `F2` are forward iterators (23.3.5.4); `c` is a value of type `X::string_type`; `s` is an object of type `X::string_type`; `cs` is an object of type `const X::string_type`; `b` is a value of type `bool`; `I` is a value of type `int`; `cl` is an object of type `X::char_class_type`, and `loc` is an object of type `X::locale_type`.

#### Table 135: Regular expression traits class requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>X::char_type</code></td>
<td><code>charT</code></td>
<td>The character container type used in the implementation of class template <code>basic_regex</code>.</td>
</tr>
<tr>
<td><code>X::string_type</code></td>
<td><code>basic_string&lt;charT&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>X::locale_type</code></td>
<td>A copy constructible type</td>
<td>A type that represents the locale used by the traits class.</td>
</tr>
<tr>
<td><code>X::char_class_type</code></td>
<td>A bitmask type (16.4.2.2.4).</td>
<td>A bitmask type representing a particular character classification.</td>
</tr>
<tr>
<td><code>X::length(p)</code></td>
<td><code>size_t</code></td>
<td>Yields the smallest <code>i</code> such that <code>p[i] == 0</code>. Complexity is linear in <code>i</code>.</td>
</tr>
<tr>
<td><code>v.translate(c)</code></td>
<td><code>X::char_type</code></td>
<td>Returns a character such that for any character <code>d</code> that is to be considered equivalent to <code>c</code> then <code>v.translate(c) == v.translate(d)</code>.</td>
</tr>
<tr>
<td><code>v.translate_nocase(c)</code></td>
<td><code>X::char_type</code></td>
<td>For all characters <code>C</code> that are to be considered equivalent to <code>c</code> when comparisons are to be performed without regard to case, then <code>v.translate_nocase(c) == v.translate_nocase(C)</code>.</td>
</tr>
<tr>
<td><code>v.transform(F1, F2)</code></td>
<td><code>X::string_type</code></td>
<td>Returns a sort key for the character sequence designated by the iterator range <code>[F1, F2)</code> such that if the character sequence <code>[G1, G2)</code> sorts before the character sequence <code>[H1, H2)</code> then <code>v.transform(G1, G2) &lt; v.transform(H1, H2)</code>.</td>
</tr>
<tr>
<td><code>v.transform_primary(F1, F2)</code></td>
<td><code>X::string_type</code></td>
<td>Returns a sort key for the character sequence designated by the iterator range <code>[F1, F2)</code> such that if the character sequence <code>[G1, G2)</code> sorts before the character sequence <code>[H1, H2)</code> when character case is not considered then <code>v.transform_primary(G1, G2) &lt; v.transform_primary(H1, H2)</code>.</td>
</tr>
</tbody>
</table>
### Table 135: Regular expression traits class requirements (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>v.lookup_collatename(F1, F2)</code></td>
<td><code>X::string_type</code></td>
<td>Returns a sequence of characters that represents the collating element consisting of the character sequence designated by the iterator range <code>[F1, F2)</code>. Returns an empty string if the character sequence is not a valid collating element.</td>
</tr>
<tr>
<td><code>v.lookup_classname(F1, F2, b)</code></td>
<td><code>X::char_class_type</code></td>
<td>Converts the character sequence designated by the iterator range <code>[F1, F2)</code> into a value of a bitmask type that can subsequently be passed to <code>isctype</code>. Values returned from <code>lookup_classname</code> can be bitwise OR ed together; the resulting value represents membership in either of the corresponding character classes. If <code>b</code> is <code>true</code>, the returned bitmask is suitable for matching characters without regard to their case. Returns 0 if the character sequence is not the name of a character class recognized by <code>X</code>. The value returned shall be independent of the case of the characters in the sequence.</td>
</tr>
<tr>
<td><code>v.isctype(c, cl)</code></td>
<td><code>bool</code></td>
<td>Returns <code>true</code> if character <code>c</code> is a member of one of the character classes designated by <code>cl</code>, <code>false</code> otherwise.</td>
</tr>
<tr>
<td><code>v.value(c, I)</code></td>
<td><code>int</code></td>
<td>Returns the value represented by the digit <code>c</code> in base <code>I</code> if the character <code>c</code> is a valid digit in base <code>I</code>; otherwise returns <code>-1</code>. [Note: The value of <code>I</code> will only be 8, 10, or 16. — end note]</td>
</tr>
<tr>
<td><code>u.imbue(loc)</code></td>
<td><code>X::locale_type</code></td>

5 [Note: Class template `regex_traits` meets the requirements for a regular expression traits class when it is specialized for `char` or `wchar_t`. This class template is described in the header `<regex>`, and is described in 30.7. — end note]

### 30.4 Header `<regex>` synopsis

```cpp
#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.1

namespace std {
  // 30.5, regex constants
  namespace regex_constants {
    using syntax_option_type = T1;
    using match_flag_type = T2;
    using error_type = T3;
  }

  // 30.6, class regex_error
  class regex_error;

  // 30.7, class template regex_traits
  template<class charT> struct regex_traits;

  // 30.8, class template basic_regex
  template<class charT, class traits = regex_traits<charT>> class basic_regex;

  using regex = basic_regex<char>;
  using wregex = basic_regex<wchar_t>;
```

§ 30.4 1457
// 30.8.5, basic_regex swap

}

30.5 Namespace std::regex_constants

The namespace std::regex_constants holds symbolic constants used by the regular expression library. This namespace provides three types, syntax_option_type, match_flag_type, and error_type, along with several constants of these types.

30.5.1 Bitmask type syntax_option_type

namespace std::regex_constants {
    using syntax_option_type = T1;
    inline constexpr syntax_option_type icase = unspecified;
    inline constexpr syntax_option_type nosubs = unspecified;
    inline constexpr syntax_option_type optimize = unspecified;
    inline constexpr syntax_option_type collate = unspecified;
    inline constexpr syntax_option_type ECMAScript = unspecified;
    inline constexpr syntax_option_type basic = unspecified;
    inline constexpr syntax_option_type extended = unspecified;
    inline constexpr syntax_option_type awk = unspecified;
    inline constexpr syntax_option_type grep = unspecified;
    inline constexpr syntax_option_type egrep = unspecified;
    inline constexpr syntax_option_type multiline = unspecified;
}

The type syntax_option_type is an implementation-defined bitmask type (16.4.2.2.4). Setting its elements has the effects listed in Table 136. A valid value of type syntax_option_type shall have at most one of the grammar elements ECMAScript, basic, extended, awk, grep, egrep, set. If no grammar element is set, the default grammar is ECMAScript.

30.5.2 Bitmask type match_flag_type

namespace std::regex_constants {
    using match_flag_type = T2;
    inline constexpr match_flag_type match_default = {};
    inline constexpr match_flag_type match_not_bol = unspecified;
    inline constexpr match_flag_type match_not_eol = unspecified;
    inline constexpr match_flag_type match_not_bow = unspecified;
    inline constexpr match_flag_type match_not_eow = unspecified;
    inline constexpr match_flag_type match_any = unspecified;
    inline constexpr match_flag_type match_not_null = unspecified;
    inline constexpr match_flag_type match_continuous = unspecified;
}
Table 136: syntax_option_type effects  [tab:re.synopt]

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>icase</td>
<td>Specifies that matching of regular expressions against a character container sequence shall be performed without regard to case.</td>
</tr>
<tr>
<td>nosubs</td>
<td>Specifies that no sub-expressions shall be considered to be marked, so that when a regular expression is matched against a character container sequence, no sub-expression matches shall be stored in the supplied match_results object.</td>
</tr>
<tr>
<td>optimize</td>
<td>Specifies that the regular expression engine should pay more attention to the speed with which regular expressions are matched, and less to the speed with which regular expression objects are constructed. Otherwise it has no detectable effect on the program output.</td>
</tr>
<tr>
<td>collate</td>
<td>Specifies that character ranges of the form &quot;[a-b]&quot; shall be locale sensitive.</td>
</tr>
<tr>
<td>ECMAScript</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by ECMAScript in ECMA-262, as modified in 30.13. See also: ECMA-262 15.10</td>
</tr>
<tr>
<td>basic</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by basic regular expressions in POSIX. See also: POSIX, Base Definitions and Headers, Section 9.3</td>
</tr>
<tr>
<td>extended</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by extended regular expressions in POSIX. See also: POSIX, Base Definitions and Headers, Section 9.4</td>
</tr>
<tr>
<td>awk</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility awk in POSIX.</td>
</tr>
<tr>
<td>grep</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep in POSIX.</td>
</tr>
<tr>
<td>egrep</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep when given the -E option in POSIX.</td>
</tr>
<tr>
<td>multiline</td>
<td>Specifies that ^ shall match the beginning of a line and $ shall match the end of a line, if the ECMAScript engine is selected.</td>
</tr>
</tbody>
</table>

The type match_flag_type is an implementation-defined bitmask type (16.4.2.2.4). The constants of that type, except for match_default and format_default, are bitmask elements. The match_default and format_default constants are empty bitmasks. Matching a regular expression against a sequence of characters \([first, last)\) proceeds according to the rules of the grammar specified for the regular expression object, modified according to the effects listed in Table 137 for any bitmask elements set.

Table 137: regex_constants::match_flag_type effects when obtaining a match against a character container sequence \([first, last)\).  [tabre.matchflag]

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>match_not_bol</td>
<td>The first character in the sequence ([first, last)) shall be treated as though it is not at the beginning of a line, so the character ^ in the regular expression shall not match ([first, first)).</td>
</tr>
<tr>
<td>match_not_eol</td>
<td>The last character in the sequence ([first, last)) shall be treated as though it is not at the end of a line, so the character &quot;$&quot; in the regular expression shall not match ((last, last)).</td>
</tr>
<tr>
<td>match_not_bow</td>
<td>The expression (&quot;[b]&quot;) shall not match the sub-sequence ([first, first)).</td>
</tr>
<tr>
<td>match_not_eow</td>
<td>The expression (&quot;[b]&quot;) shall not match the sub-sequence ([last, last)).</td>
</tr>
<tr>
<td>match_any</td>
<td>If more than one match is possible then any match is an acceptable result.</td>
</tr>
<tr>
<td>match_not_null</td>
<td>The expression shall not match an empty sequence.</td>
</tr>
</tbody>
</table>
Table 137: `regex_constants::match_flag_type` effects when obtaining a match against a character container sequence `[first, last)` (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>match_continuous</code></td>
<td>The expression shall only match a sub-sequence that begins at <code>first</code>.</td>
</tr>
<tr>
<td><code>match_prev_avail</code></td>
<td><code>--first</code> is a valid iterator position. When this flag is set the flags <code>match_not_bol</code> and <code>match_not_bow</code> shall be ignored by the regular expression algorithms (30.11) and iterators (30.12).</td>
</tr>
<tr>
<td><code>format_default</code></td>
<td>When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the ECMAScript replace function in ECMA-262, part 15.5.4.11 String.prototype.replace. In addition, during search and replace operations all non-overlapping occurrences of the regular expression shall be located and replaced, and sections of the input that did not match the expression shall be copied unchanged to the output string.</td>
</tr>
<tr>
<td><code>format_sed</code></td>
<td>When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the sed utility in POSIX.</td>
</tr>
<tr>
<td><code>format_no_copy</code></td>
<td>During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.</td>
</tr>
<tr>
<td><code>format_first_only</code></td>
<td>When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.</td>
</tr>
</tbody>
</table>

30.5.3 Implementation-defined `error_type` [re.err]

namespace std::regex_constants {
using error_type = T3;
inline constexpr error_type error_collate = unspecified;
inline constexpr error_type error_ctype = unspecified;
inline constexpr error_type error_escape = unspecified;
inline constexpr error_type error_backref = unspecified;
inline constexpr error_type error_brack = unspecified;
inline constexpr error_type error_paren = unspecified;
inline constexpr error_type error_brace = unspecified;
inline constexpr error_type error_badbrace = unspecified;
inline constexpr error_type error_range = unspecified;
inline constexpr error_type error_space = unspecified;
inline constexpr error_type error_badrepeat = unspecified;
inline constexpr error_type error_complexity = unspecified;
inline constexpr error_type error_stack = unspecified;
}

1 The type `error_type` is an implementation-defined enumerated type (16.4.2.2.3). Values of type `error_type` represent the error conditions described in Table 138:

Table 138: `error_type` values in the C locale [tab:re.err]

<table>
<thead>
<tr>
<th>Value</th>
<th>Error condition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>error_collate</code></td>
<td>The expression contained an invalid collating element name.</td>
</tr>
<tr>
<td><code>error_ctype</code></td>
<td>The expression contained an invalid character class name.</td>
</tr>
<tr>
<td><code>error_escape</code></td>
<td>The expression contained an invalid escaped character, or a trailing escape.</td>
</tr>
<tr>
<td><code>error_backref</code></td>
<td>The expression contained an invalid back reference.</td>
</tr>
<tr>
<td><code>error_brack</code></td>
<td>The expression contained mismatched <code>{ and }</code>.</td>
</tr>
<tr>
<td><code>error_paren</code></td>
<td>The expression contained mismatched <code>{ and }</code>.</td>
</tr>
<tr>
<td><code>error_brace</code></td>
<td>The expression contained mismatched <code>{ and }</code>.</td>
</tr>
<tr>
<td><code>error_badbrace</code></td>
<td>The expression contained an invalid range in a <code>{</code> expression.</td>
</tr>
<tr>
<td><code>error_range</code></td>
<td>The expression contained an invalid character range, such as <code>[b-a]</code> in most encodings.</td>
</tr>
<tr>
<td><code>error_space</code></td>
<td>There was insufficient memory to convert the expression into a finite state machine.</td>
</tr>
<tr>
<td><code>error_badrepeat</code></td>
<td>One of <code>*?+{</code> was not preceded by a valid regular expression.</td>
</tr>
</tbody>
</table>
### Table 138: error_type values in the C locale (continued)

<table>
<thead>
<tr>
<th>Value</th>
<th>Error condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_complexity</td>
<td>The complexity of an attempted match against a regular expression exceeded a pre-set level.</td>
</tr>
<tr>
<td>error_stack</td>
<td>There was insufficient memory to determine whether the regular expression could match the specified character sequence.</td>
</tr>
</tbody>
</table>

#### 30.6 Class `regex_error`

```cpp
class regex_error : public runtime_error {
public:
    explicit regex_error(regex_constants::error_type ecode);
    regex_constants::error_type code() const;
};
```

1. The class `regex_error` defines the type of objects thrown as exceptions to report errors from the regular expression library.

```cpp
regex_error(regex_constants::error_type ecode);
```

2. **Postconditions:** ecode == code().

```cpp
regex_constants::error_type code() const;
```

3. **Returns:** The error code that was passed to the constructor.

#### 30.7 Class template `regex_traits`

```cpp
namespace std {
    template<class charT>
    struct regex_traits {
        using char_type = charT;
        using string_type = basic_string<char_type>
        using locale_type = locale;
        using char_class_type = bitmask_type;

        regex_traits();
        static size_t length(const char_type* p);
        charT translate(charT c) const;
        charT translate_nocase(charT c) const;
        template<class ForwardIterator>
        string_type transform(ForwardIterator first, ForwardIterator last) const;
        template<class ForwardIterator>
        string_type transform_primary(ForwardIterator first, ForwardIterator last) const;
        template<class ForwardIterator>
        string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;
        template<class ForwardIterator>
        char_class_type lookup_classname(ForwardIterator first, ForwardIterator last, bool icase = false) const;
        bool isctype(charT c, char_class_type f) const;
        int value(charT ch, int radix) const;
        locale_type imbue(locale_type l);
        locale_type getloc() const;
    };
}
```

1. The specializations `regex_traits<char>` and `regex_traits<wchar_t>` meet the requirements for a regular expression traits class (30.3).

```cpp
using char_class_type = bitmask_type;
```

2. The type `char_class_type` is used to represent a character classification and is capable of holding an implementation specific set returned by `lookup_classname`.

§ 30.7
static size_t length(const char_type* p);

Returns: char_traits<charT>::length(p).

charT translate(charT c) const;

Returns: c.

charT translate_nocase(charT c) const;

Returns: use_facet<ctype<charT>>(getloc()).tolower(c).

template<class ForwardIterator>
string_type transform(ForwardIterator first, ForwardIterator last) const;

Effects: As if by:

string_type str(first, last);
return use_facet<collate<charT>>(getloc()).transform(str.data(), str.data() + str.length());

template<class ForwardIterator>
string_type transform_primary(ForwardIterator first, ForwardIterator last) const;

Effects: If
typeid(use_facet<collate<charT>>)
and the form of the sort key returned by collate_byname<charT>::transform(first, last) is known
and can be converted into a primary sort key then returns that key, otherwise returns an empty string.

template<class ForwardIterator>
string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;

Returns: A sequence of one or more characters that represents the collating element consisting of the character
sequence designated by the iterator range [first, last). Returns an empty string if the character sequence
is not a valid collating element.

template<class ForwardIterator>
char_class_type lookup_classname(
    ForwardIterator first, ForwardIterator last, bool icase = false) const;

Returns: An unspecified value that represents the character classification named by the character sequence
designated by the iterator range [first, last). If the parameter icase is true then the returned mask
identifies the character classification without regard to the case of the characters being matched, otherwise it
does honor the case of the characters being matched. The value returned shall be independent of the case
of the characters in the character sequence. If the name is not recognized then returns char_class_type().

Remarks: For regex_traits<char>, at least the narrow character names in Table 139 shall be recognized. For
regex_traits<wchar_t>, at least the wide character names in Table 139 shall be recognized.

bool isctype(charT c, char_class_type f) const;

Effects: Determines if the character c is a member of the character classification represented by f.

Returns: Given the following function declaration:

// for exposition only
template<class C>
ctype_base::mask convert(typename regex_traits<C>::char_class_type f);

that returns a value in which each ctype_base::mask value corresponding to a value in f named in Table 139
is set, then the result is determined as if by:

cctype_base::mask m = convert<charT>(f);
const cctype<charT>& ct = use_facet<cctype<charT>>(getloc());
if (ct.is(m, c)) {
    return true;
} else if (c == ct.widen('_')) {
    charT w[1] = { ct.widen('w') }; 
    char_class_type x = lookup_classname(w, w+1);

325) For example, if the parameter icase is true then [[:lower:]] is the same as [[:alpha:]].
return (f&x) == x;
} else {
    return false;
}

[Example:
regex_traits<char> t;
string d("d");
string u("upper");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(d.begin(), d.end());
f |= t.lookup_classname(u.begin(), u.end());
cctype_base::mask m = convert<char>(f); // m == ctype_base::digit|ctype_base::upper
— end example]

Example: [Example:
regex_traits<char> t;
string w("w");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(w.begin(), w.end());
t.isctype('A', f); // returns true
t.isctype('_', f); // returns true
t.isctype(' ', f); // returns false
— end example]

int value(charT ch, int radix) const;

Preconditions: The value of radix is 8, 10, or 16.

Returns: The value represented by the digit ch in base radix if the character ch is a valid digit in base radix; otherwise returns -1.

locale_type imbue(locale_type loc);

Effects: Imbues this with a copy of the locale loc. [Note: Calling imbue with a different locale than the one currently in use invalidates all cached data held by *this. — end note]

Postconditions: getloc() == loc.

Returns: If no locale has been previously imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.

locale_type getloc() const;

Returns: If no locale has been imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.

30.8 Class template basic_regex

1 For a char-like type charT, specializations of class template basic_regex represent regular expressions constructed from character sequences of charT characters. In the rest of 30.8, charT denotes a given char-like type. Storage for a regular expression is allocated and freed as necessary by the member functions of class basic_regex.

2 Objects of type specialization of basic_regex are responsible for converting the sequence of charT objects to an internal representation. It is not specified what form this representation takes, nor how it is accessed by algorithms that operate on regular expressions. [Note: Implementations will typically declare some function templates as friends of basic_regex to achieve this. — end note]

3 The functions described in this Clause report errors by throwing exceptions of type regex_error.

```cpp
namespace std {
    template<class charT, class traits = regex_traits<charT>>
    class basic_regex {
    public:
        // types
        using value_type = charT;
        using traits_type = traits;
        using string_type = typename traits::string_type;
        using flag_type = regex_constants::syntax_option_type;
        using locale_type = typename traits::locale_type;

        // 30.5.1, constants
        static constexpr flag_type icase = regex_constants::icase;
        static constexpr flag_type nosubs = regex_constants::nosubs;
        static constexpr flag_type optimize = regex_constants::optimize;
        static constexpr flag_type collate = regex_constants::collate;
        static constexpr flag_type ECMAScript = regex_constants::ECMAScript;
        static constexpr flag_type basic = regex_constants::basic;
        static constexpr flag_type extended = regex_constants::extended;
        static constexpr flag_type awk = regex_constants::awk;
        static constexpr flag_type grep = regex_constants::grep;
        static constexpr flag_type egrep = regex_constants::egrep;
        static constexpr flag_type multiline = regex_constants::multiline;

        // 30.8.1, construct/copy/destroy
        basic_regex();
        explicit basic_regex(const charT* p, flag_type f = regex_constants::ECMAScript);
        basic_regex(const charT* p, size_t len, flag_type f = regex_constants::ECMAScript);
        basic_regex(const basic_regex&);
        basic_regex(basic_regex&&) noexcept;
        template<class ST, class SA>
        explicit basic_regex(const basic_string<charT, ST, SA>& s, flag_type f = regex_constants::ECMAScript);
        template<class ForwardIterator>
        basic_regex(ForwardIterator first, ForwardIterator last, flag_type f = regex_constants::ECMAScript);
        basic_regex(initializer_list<charT> il, flag_type f = regex_constants::ECMAScript);
    ~basic_regex();

        // 30.8.2, assign
        basic_regex& operator=(const basic_regex& e);
        basic_regex& operator=(basic_regex&& e) noexcept;
        basic_regex& operator=(const charT* p);
        basic_regex& operator=(initializer_list<charT> il);
        template<class ST, class SA>
        basic_regex& operator=(const basic_string<charT, ST, SA>& s);
        basic_regex& assign(const basic_regex& e);
        basic_regex& assign(basic_regex&& e) noexcept;
        basic_regex& assign(const charT* p, flag_type f = regex_constants::ECMAScript);
        basic_regex& assign(const charT* p, size_t len, flag_type f = regex_constants::ECMAScript);
    }
```
template<class ST, class SA>
    basic_regex& assign(const basic_string<charT, ST, SA>& s,
                        flag_type f = regex_constants::ECMAScript);

template<class InputIterator>
    basic_regex& assign(InputIterator first, InputIterator last,
                        flag_type f = regex_constants::ECMAScript);

basic_regex& assign(initializer_list<charT>,
                     flag_type f = regex_constants::ECMAScript);

// 30.8.3, const operations
unsigned mark_count() const;
flag_type flags() const;

// 30.8.4, locale
locale_type imbue(locale_type loc);
locale_type getloc() const;

// 30.8.5, swap
void swap(basic_regex&);
};

template<class ForwardIterator>
    basic_regex(ForwardIterator, ForwardIterator,
                regex_constants::syntax_option_type = regex_constants::ECMAScript)
    -> basic_regex<typename iterator_traits<ForwardIterator>::value_type>;

30.8.1 Constructors

basic_regex();

Postconditions: *this does not match any character sequence.

explicit basic_regex(const charT* p, flag_type f = regex_constants::ECMAScript);

Preconditions: [p, p + char_traits<charT>::length(p)) is a valid range.
Effects: The object’s internal finite state machine is constructed from the regular expression contained in the sequence of characters [p, p + char_traits<charT>::length(p)), and interpreted according to the flags f.
Postconditions: flags() returns f.mark_count() returns the number of marked sub-expressions within the expression.
Throws: regex_error if [p, p + char_traits<charT>::length(p)) is not a valid regular expression.

basic_regex(const charT* p, size_t len, flag_type f = regex_constants::ECMAScript);

Preconditions: [p, p + len) is a valid range.
Effects: The object’s internal finite state machine is constructed from the regular expression contained in the sequence of characters [p, p + len), and interpreted according the flags specified in f.
Postconditions: flags() returns f.mark_count() returns the number of marked sub-expressions within the expression.
Throws: regex_error if [p, p + len) is not a valid regular expression.

basic_regex(const basic_regex& e);

Postconditions: flags() and mark_count() return e.flags() and e.mark_count(), respectively.

basic_regex(basic_regex&& e) noexcept;

Postconditions: flags() and mark_count() return the values that e.flags() and e.mark_count(), respectively, had before construction.

template<class ST, class SA>
    explicit basic_regex(const basic_string<charT, ST, SA>& s,
flag_type f = regex_constants::ECMAScript);

Effects: The object’s internal finite state machine is constructed from the regular expression contained in the string s, and interpreted according to the flags specified in f.

Postconditions: flags() returns f.mark_count() returns the number of marked sub-expressions within the expression.

Throws: regex_error if s is not a valid regular expression.

template<class ForwardIterator>
basic_regex(ForwardIterator first, ForwardIterator last,
flag_type f = regex_constants::ECMAScript);

Effects: The object’s internal finite state machine is constructed from the regular expression contained in the sequence of characters [first, last), and interpreted according to the flags specified in f.

Postconditions: flags() returns f.mark_count() returns the number of marked sub-expressions within the expression.

Throws: regex_error if the sequence [first, last) is not a valid regular expression.

basic_regex(initializer_list<charT> il, flag_type f = regex_constants::ECMAScript);

Effects: Same as basic_regex(il.begin(), il.end(), f).

30.8.2 Assignment

basic_regex& operator=(const basic_regex& e);

Postconditions: flags() and mark_count() return e.flags() and e.mark_count(), respectively.

basic_regex& operator=(basic_regex&& e) noexcept;

Postconditions: flags() and mark_count() return the values that e.flags() and e.mark_count(), respectively, had before assignment. e is in a valid state with unspecified value.

basic_regex& operator=(const charT* p);

Effects: Equivalent to: return assign(p);

basic_regex& operator=(initializer_list<charT> il);

Effects: Equivalent to: return assign(il.begin(), il.end());

template<class ST, class SA>
basic_regex& operator=(const basic_string<charT, ST, SA>& s);

Effects: Equivalent to: return assign(s);

basic_regex& assign(const basic_regex& e);

Effects: Equivalent to: return *this = e;

basic_regex& assign(basic_regex&& e) noexcept;

Effects: Equivalent to: return *this = std::move(e);

basic_regex& assign(const charT* p, flag_type f = regex_constants::ECMAScript);

Effects: Equivalent to: return assign(string_type(p), f);

basic_regex& assign(const charT* p, size_t len, flag_type f = regex_constants::ECMAScript);

Effects: Equivalent to: return assign(string_type(p, len), f);

template<class ST, class SA>
basic_regex& assign(const basic_string<charT, ST, SA>& s,
flag_type f = regex_constants::ECMAScript);

Returns: *this.

Effects: Assigns the regular expression contained in the string s, interpreted according the flags specified in f. If an exception is thrown, *this is unchanged.
Postconditions: If no exception is thrown, flags() returns \( f \) and mark_count() returns the number of marked sub-expressions within the expression.

Throws: regex_error if \( s \) is not a valid regular expression.

```cpp
template<class InputIterator>
void assign(InputIterator first, InputIterator last,
flag_type f = regex_constants::ECMAScript);
```

**Effects:** Equivalent to: return assign(string_type(first, last), f);

```cpp
basic_regex& assign(initializer_list<charT> il,
flag_type f = regex_constants::ECMAScript);
```

**Effects:** Equivalent to: return assign(il.begin(), il.end(), f);

### 30.8.3 Constant operations

```cpp
unsigned mark_count() const;
```

**Effects:** Returns the number of marked sub-expressions within the regular expression.

```cpp
flag_type flags() const;
```

**Effects:** Returns a copy of the regular expression syntax flags that were passed to the object’s constructor or to the last call to assign.

### 30.8.4 Locale

```cpp
locale_type imbue(locale_type loc);
```

**Effects:** Returns the result of \( \text{traits}_\text{inst}.\text{imbue}(\text{loc}) \) where \( \text{traits}_\text{inst} \) is a (default-initialized) instance of the template type argument \( \text{traits} \) stored within the object. After a call to imbue the basic_regex object does not match any character sequence.

```cpp
locale_type getloc() const;
```

**Effects:** Returns the result of \( \text{traits}_\text{inst}.\text{getloc()} \) where \( \text{traits}_\text{inst} \) is a (default-initialized) instance of the template parameter \( \text{traits} \) stored within the object.

### 30.8.5 Swap

```cpp
void swap(basic_regex& e);
```

**Effects:** Swaps the contents of the two regular expressions.

**Postconditions:** \( \star \text{this} \) contains the regular expression that was in \( e \), \( e \) contains the regular expression that was in \( \star \text{this} \).

**Complexity:** Constant time.

### 30.8.6 Non-member functions

```cpp
template<class charT, class traits>
void swap(basic_regex<charT, traits>& lhs, basic_regex<charT, traits>& rhs);
```

**Effects:** Calls \( \text{lhs}.\text{swap}(\text{rhs}) \).

### 30.9 Class template sub_match

Class template sub_match denotes the sequence of characters matched by a particular marked sub-expression.

```cpp
namespace std {
    template<class BidirectionalIterator>
    class sub_match : public pair<BidirectionalIterator, BidirectionalIterator> {
        public:
            using value_type = typename iterator_traits<BidirectionalIterator>::value_type;
            using difference_type = typename iterator_traits<BidirectionalIterator>::difference_type;
            using iterator = BidirectionalIterator;
            using string_type = basic_string<value_type>;
    }
}
```
30.9.1 Members

**constexpr sub_match();**

**Effects:** Value-initializes the pair base class subobject and the member `matched`.

**difference_type length() const;**

**Returns:** `matched` ? `distance(first, second)` : 0.

**operator string_type() const;**

**Returns:** `matched` ? `string_type(first, second)` : `string_type()`.

**string_type str() const;**

**Returns:** `matched` ? `string_type(first, second)` : `string_type()`.

**int compare(const sub_match& s) const;**

**Returns:** `str().compare(s.str())`.

**int compare(const string_type& s) const;**

**Returns:** `str().compare(s)`.

**int compare(const value_type* s) const;**

**Returns:** `str().compare(s)`.

30.9.2 Non-member operators

Let `SM-CAT(I)` be

```cpp
compare_three_way_result_t<basic_string<typename iterator_traits<I>::value_type>>
```

**template<class BiIter>**

```cpp
bool operator==(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

**Returns:** `lhs.compare(rhs) == 0`.

**template<class BiIter>**

```cpp
auto operator<=>(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
```

**Returns:** `static_cast<SM-CAT(BiIter)>(lhs.compare(rhs) <=> 0)`.

**template<class BiIter, class ST, class SA>**

```cpp
bool operator==(const sub_match<BiIter>& lhs, const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
```

**Returns:**

```cpp
lhs.compare(typename sub_match<BiIter>::string_type(rhs.data(), rhs.size())) == 0
```
template<class BiIter, class ST, class SA>
auto operator<=>(
    const sub_match<BiIter>& lhs,
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);
5
Returns:
    static_cast<SM-CAT(BiIter)>(lhs.compare(
        typename sub_match<BiIter>::string_type(rhs.data(), rhs.size())
        <=> 0
    )
)

template<class BiIter>
bool operator==((const sub_match<BiIter>& lhs,
    const typename iterator_traits<BiIter>::value_type* rhs);
6
Returns: lhs.compare(rhs) == 0.

template<class BiIter>
auto operator<=>((const sub_match<BiIter>& lhs,
    const typename iterator_traits<BiIter>::value_type* rhs);
7
Returns: static_cast<SM-CAT(BiIter)>(lhs.compare(rhs) <=> 0).

template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs,
    const typename iterator_traits<BiIter>::value_type& rhs);
8
Returns: lhs.compare(typename sub_match<BiIter>::string_type(1, rhs)) == 0.

template<class BiIter>
auto operator<=>(const sub_match<BiIter>& lhs,
    const typename iterator_traits<BiIter>::value_type& rhs);
9
Returns:
    static_cast<SM-CAT(BiIter)>(lhs.compare(
        typename sub_match<BiIter>::string_type(1, rhs)
        <=> 0
    )
)

template<class charT, class ST, class BiIter>
basic_ostream<charT, ST>&
    operator<<(basic_ostream<charT, ST>&& os, const sub_match<BiIter>& m);
10
Returns: os << m.str().

30.10 Class template match_results
1
Class template match_results denotes a collection of character sequences representing the result of a regular
expression match. Storage for the collection is allocated and freed as necessary by the member functions of class
template match_results.

2 The class template match_results meets the requirements of an allocator-aware container and of a sequence
container (22.2.1, 22.2.3) except that only copy assignment, move assignment, and operations defined for const-
qualified sequence containers are supported and that the semantics of comparison functions are different from those
required for a container.

3 A default-constructed match_results object has no fully established result state. A match result is ready when,
as a consequence of a completed regular expression match modifying such an object, its result state becomes fully
established. The effects of calling most member functions from a match_results object that is not ready are
undefined.

4 The sub_match object stored at index 0 represents sub-expression 0, i.e., the whole match. In this case the sub_-
match member matched is always true. The sub_match object stored at index n denotes what matched the marked
sub-expression n within the matched expression. If the sub-expression n participated in a regular expression match
then the sub_match member matched evaluates to true, and members first and second denote the range of
characters [first, second) which formed that match. Otherwise matched is false, and members first and
second point to the end of the sequence that was searched. [Note: The sub_match objects representing different
sub-expressions that did not participate in a regular expression match need not be distinct. — end note]
namespace std {

class match_results {
    public:
        using value_type = sub_match<BidirectionalIterator>;
        using const_reference = const value_type&;
        using reference = value_type&;
        using const_iterator = implementation-defined;
        using iterator = const_iterator;
        using difference_type =
            typename iterator_traits<BidirectionalIterator>::difference_type;
        using size_type = typename allocator_traits<Allocator>::size_type;
        using allocator_type = Allocator;
        using char_type =
            typename iterator_traits<BidirectionalIterator>::value_type;
        using string_type = basic_string<char_type>;

        // 30.10.1, construct/copy/destroy
        match_results() : match_results(Allocator()) {}  
        explicit match_results(const Allocator&);  
        match_results(const match_results& m);  
        match_results(match_results&& m) noexcept;  
        match_results& operator=(const match_results& m);  
        match_results& operator=(match_results&& m);  
        ~match_results();

        // 30.10.2, state
        bool ready() const;

        // 30.10.3, size
        size_type size() const;
        size_type max_size() const;
        [[nodiscard]] bool empty() const;

        // 30.10.4, element access
        difference_type length(size_type sub = 0) const;
        difference_type position(size_type sub = 0) const;
        string_type str(size_type sub = 0) const;
        const_reference operator[](size_type n) const;
        const_reference prefix() const;
        const_reference suffix() const;
        const_iterator begin() const;
        const_iterator end() const;
        const_iterator cbegin() const;
        const_iterator cend() const;

        // 30.10.5, format
        template<class OutputIter>
        OutputIter
            format(OutputIter out,
            const char_type* fmt_first, const char_type* fmt_last,
            regex_constants::match_flag_type flags = regex_constants::format_default) const;
        template<class OutputIter, class ST, class SA>
        OutputIter
            format(OutputIter out,
            const basic_string<char_type, ST, SA>& fmt,
            regex_constants::match_flag_type flags = regex_constants::format_default) const;
        template<class ST, class SA>
        basic_string<char_type, ST, SA>
            format(const basic_string<char_type, ST, SA>& fmt,
            regex_constants::match_flag_type flags = regex_constants::format_default) const;
    }
}

§ 30.10 1473
string_type
   format(const char_type* fmt,
          regex_constants::match_flag_type flags = regex_constants::format_default) const;

   // 30.10.6, allocator
   allocator_type get_allocator() const;

   // 30.10.7, swap
   void swap(match_results& that);
);

30.10.1 Constructors

   explicit match_results(const Allocator& a);

   // Postconditions: ready() returns false, size() returns 0.
   match_results(match_results&& m) noexcept;

   // Effects: The stored Allocator value is move constructed from m.get_allocator().
   Postconditions: As specified in Table 140.

   match_results& operator=(const match_results& m);

   // Postconditions: As specified in Table 140.

   match_results& operator=(match_results&& m);

   // Postconditions: As specified in Table 140.

Table 140: match_results assignment operator effects

</tbody>
</table>

30.10.2 State

   bool ready() const;

   // Returns: true if *this has a fully established result state, otherwise false.

30.10.3 Size

   size_type size() const;

   // Returns: One plus the number of marked sub-expressions in the regular expression that was matched if *this represents the result of a successful match. Otherwise returns 0. [Note: The state of a match_results object can be modified only by passing that object to regex_match or regex_search. Subclauses 30.11.2 and 30.11.3 specify the effects of those algorithms on their match_results arguments. —end note]

   size_type max_size() const;

   // Returns: The maximum number of sub_match elements that can be stored in *this.

   [[nodiscard]] bool empty() const;

   // Returns: size() == 0.
30.10.4 Element access

```cpp
difference_type length(size_type sub = 0) const;
```

1
Preconditions: ready() == true.

2
Returns: (*this)[sub].length().

difference_type position(size_type sub = 0) const;

3
Preconditions: ready() == true.

4
Returns: The distance from the start of the target sequence to (*this)[sub].first.

string_type str(size_type sub = 0) const;

5
Preconditions: ready() == true.

6
Returns: string_type((*this)[sub]).

const_reference operator[](size_type n) const;

7
Preconditions: ready() == true.

8
Returns: A reference to the sub_match object representing the character sequence that matched marked sub-expression n. If n == 0 then returns a reference to a sub_match object representing the character sequence that matched the whole regular expression. If n >= size() then returns a sub_match object representing an unmatched sub-expression.

const_reference prefix() const;

9
Preconditions: ready() == true.

10
Returns: A reference to the sub_match object representing the character sequence from the start of the string being matched/searched to the start of the match found.

const_reference suffix() const;

11
Preconditions: ready() == true.

12
Returns: A reference to the sub_match object representing the character sequence from the end of the match found to the end of the string being matched/searched.

const_iterator begin() const;
const_iterator cbegin() const;

13
Returns: A starting iterator that enumerates over all the sub-expressions stored in *this.

cost_iterator end() const;
cost_iterator cend() const;

14
Returns: A terminating iterator that enumerates over all the sub-expressions stored in *this.

30.10.5 Formatting

```cpp
template<class OutputIter>
OutputIter format(
   const char_type* fmt_first, const char_type* fmt_last,
   regex_constants::match_flag_type flags = regex_constants::format_default) const;
```

1
Preconditions: ready() == true and OutputIter meets the requirements for a Cpp17OutputIterator (23.3.5.3).

2
Effects: Copies the character sequence [fmt_first, fmt_last) to OutputIter out. Replaces each format specifier or escape sequence in the copied range with either the character(s) it represents or the sequence of characters within *this to which it refers. The bitmasks specified in flags determine which format specifiers and escape sequences are recognized.

3
Returns: out.

```cpp
template<class OutputIter, class ST, class SA>
OutputIter format(
   const basic_string<char_type, ST, SA>& fmt,
```

§ 30.10.5
regex_constants::match_flag_type flags = regex_constants::format_default) const;

Effects: Equivalent to:

return format(out, fmt.data(), fmt.data() + fmt.size(), flags);

template<class ST, class SA>
basic_string<char_type, ST, SA> format(
const basic_string<char_type, ST, SA>& fmt,
regex_constants::match_flag_type flags = regex_constants::format_default) const;

Preconditions: ready() == true.

Effects: Constructs an empty string result of type basic_string<char_type, ST, SA> and calls:

format(back_inserter(result), fmt, flags);

Returns: result.

string_type format(
const char_type* fmt,
regex_constants::match_flag_type flags = regex_constants::format_default) const;

Preconditions: ready() == true.

Effects: Constructs an empty string result of type string_type and calls:

format(back_inserter(result), fmt, fmt + char_traits<char_type>::length(fmt), flags);

Returns: result.

30.10.6 Allocator

allocator_type get_allocator() const;

Returns: A copy of the Allocator that was passed to the object’s constructor or, if that allocator has been replaced, a copy of the most recent replacement.

30.10.7 Swap

void swap(match_results& that);

Effects: Swaps the contents of the two sequences.

Postconditions: *this contains the sequence of matched sub-expressions that were in that, that contains the sequence of matched sub-expressions that were in *this.

Complexity: Constant time.

template<class BidirectionalIterator, class Allocator>
void swap(match_results<BidirectionalIterator, Allocator>& m1, match_results<BidirectionalIterator, Allocator>& m2);

Effects: As if by m1.swap(m2).

30.10.8 Non-member functions

template<class BidirectionalIterator, class Allocator>
bool operator==(const match_results<BidirectionalIterator, Allocator>& m1, const match_results<BidirectionalIterator, Allocator>& m2);

Returns: true if neither match result is ready, false if one match result is ready and the other is not. If both match results are ready, returns true only if:

- m1.empty() && m2.empty(), or
- !m1.empty() && !m2.empty(), and the following conditions are satisfied:
  - m1.prefix() == m2.prefix(),
  - m1.size() == m2.size() && equal(m1.begin(), m1.end(), m2.begin()), and
  - m1.suffix() == m2.suffix().

[Note: The algorithm equal is defined in Clause 25. — end note]
30.11 Regular expression algorithms

30.11.1 Exceptions

The algorithms described in subclause 30.11 may throw an exception of type `regex_error`. If such an exception `e` is thrown, `e.code()` shall return either `regex_constants::error_complexity` or `regex_constants::error_stack`.

30.11.2 regex_match

```cpp
template<class BidirectionalIterator, class Allocator, class charT, class traits>
bool regex_match(BidirectionalIterator first, BidirectionalIterator last, 
    match_results<BidirectionalIterator, Allocator>& m, 
    const basic_regex<charT, traits>& e, 
    regex_constants::match_flag_type flags = regex_constants::match_default);
```

**Preconditions:** BidirectionalIterator meets the Cpp17BidirectionalIterator requirements (23.3.5.5).

**Effects:** Determines whether there is a match between the regular expression `e`, and all of the character sequence `[first, last)`. The parameter `flags` is used to control how the expression is matched against the character sequence. When determining if there is a match, only potential matches that match the entire character sequence are considered. Returns `true` if such a match exists, `false` otherwise. [Example:

```cpp
std::regex re("Get|GetValue");
std::cmatch m;
regex_search("GetValue", m, re); // returns true, and m[0] contains "Get"
regex_match ("GetValue", m, re); // returns true, and m[0] contains "GetValue"
regex_search("GetValues", m, re); // returns true, and m[0] contains "Get"
regex_match ("GetValues", m, re); // returns false
```

— end example]

**Postconditions:** `m.ready() == true` in all cases. If the function returns `false`, then the effect on parameter `m` is unspecified except that `m.size()` returns 0 and `m.empty()` returns true. Otherwise the effects on parameter `m` are given in Table 141.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>m.size()</code></td>
<td><code>1 + e.mark_count()</code></td>
</tr>
<tr>
<td><code>m.empty()</code></td>
<td><code>false</code></td>
</tr>
<tr>
<td><code>m.prefix().first</code></td>
<td><code>first</code></td>
</tr>
<tr>
<td><code>m.prefix().second</code></td>
<td><code>first</code></td>
</tr>
<tr>
<td><code>m.prefix().matched</code></td>
<td><code>false</code></td>
</tr>
<tr>
<td><code>m.suffix().first</code></td>
<td><code>last</code></td>
</tr>
<tr>
<td><code>m.suffix().second</code></td>
<td><code>last</code></td>
</tr>
<tr>
<td><code>m.suffix().matched</code></td>
<td><code>false</code></td>
</tr>
<tr>
<td><code>m[0].first</code></td>
<td><code>first</code></td>

</tr>
<tr>
<td><code>m[n].matched</code></td>
<td>For all integers <code>0 &lt; n &lt; m.size()</code>, <code>true</code> if sub-expression n participated in the match, <code>false</code> otherwise.</td>
</tr>
</tbody>
</table>

```cpp
template<class BidirectionalIterator, class charT, class traits>
bool regex_match(BidirectionalIterator first, BidirectionalIterator last, 
    const basic_regex<charT, traits>& e,
```
```c++
regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Behaves "as if" by constructing an instance of match_results<BidirectionalIterator> what, and then returning the result of regex_match(first, last, what, e, flags).

30.11.3  regex_search

template<class BidirectionalIterator, class Allocator, class charT, class traits>
bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
match_results<BidirectionalIterator>& m,
const basic_regex<charT, traits>& e,
regex_constants::match_flag_type flags = regex_constants::match_default);

Preconditions: BidirectionalIterator meets the Cpp17BidirectionalIterator requirements (23.3.5.5).
Effects: Determines whether there is some sub-sequence within [first, last) that matches the regular expression e. The parameter flags is used to control how the expression is matched against the character sequence. Returns true if such a sequence exists, false otherwise.
Postconditions: m.ready() == true in all cases. If the function returns false, then the effect on parameter m is unspecified except that m.size() returns 0 and m.empty() returns true. Otherwise the effects on parameter m are given in Table 142.

Table 142: Effects of regex_search algorithm

</tbody>
</table>

```
template<class charT, class Allocator, class traits>
bool regex_search(const charT* str, match_results<const charT*, Allocator>& m,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags = regex_constants::match_default);

4 Returns: regex_search(str, str + char_traits<charT>::length(str), m, e, flags).
```

```
template<class ST, class SA, class Allocator, class charT, class traits>
bool regex_search(const basic_string<charT, ST, SA>& s,
                   match_results<typename basic_string<charT, ST, SA>::const_iterator,
                                 Allocator>& m,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags = regex_constants::match_default);

5 Returns: regex_search(s.begin(), s.end(), m, e, flags).
```

```
template<class BidirectionalIterator, class charT, class traits>
bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags = regex_constants::match_default);

6 Effects: Behaves "as if" by constructing an object what of type match_results<BidirectionalIterator> and returning regex_search(first, last, what, e, flags).
```

```
template<class charT, class traits>
bool regex_search(const charT* str,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags = regex_constants::match_default);

7 Returns: regex_search(str, str + char_traits<charT>::length(str), e, flags).
```

```
template<class ST, class SA, class charT, class traits>
bool regex_search(const basic_string<charT, ST, SA>& s,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags = regex_constants::match_default);

8 Returns: regex_search(s.begin(), s.end(), e, flags).
```

### 30.11.4 regex_replace

```
template<class OutputIterator, class BidirectionalIterator,
           class traits, class charT, class ST, class SA>
OutputIterator
regex_replace(OutputIterator out,
              BidirectionalIterator first, BidirectionalIterator last,
              const basic_regex<charT, traits>& e,
              const basic_string<charT, ST, SA>& fmt,
              regex_constants::match_flag_type flags = regex_constants::match_default);
```

§ 30.11.4
template<class OutputIterator, class BidirectionalIterator, class traits, class charT>
OutputIterator
regex_replace(OutputIterator out,
BidirectionalIterator first, BidirectionalIterator last,
const basic_regex<charT, traits>& e,
const charT* fmt, // Note: The code snippet seems to have a syntax error here.
regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs a regex_iterator object i as if by
regex_iterator<BidirectionalIterator, charT, traits> i(first, last, e, flags)
and uses i to enumerate through all of the matches m of type match_results<BidirectionalIterator>
that occur within the sequence [first, last). If no such matches are found and !(flags & regex_-
constants::format_no_copy), then calls
out = copy(first, last, out)

If any matches are found then, for each such match:

1. If !(flags & regex_constants::format_no_copy), calls
   out = copy(m.prefix().first, m.prefix().second, out)

2. Then calls
   out = m.format(out, fmt, flags)
   for the first form of the function and
   out = m.format(out, fmt, fmt + char_traits<charT>::length(fmt), flags)
   for the second.

Finally, if such a match is found and !(flags & regex_constants::format_first_only) is nonzero, then only the first match found is replaced.

Returns: out.

template<class traits, class charT, class ST, class SA, class FST, class FSA>
basic_string<charT, ST, SA>
regex_replace(const basic_string<charT, ST, SA>& s,
const basic_regex<charT, traits>& e,
const basic_string<charT, FST, FSA>& fmt,
regex_constants::match_flag_type flags = regex_constants::match_default);

template<class traits, class charT, class ST, class SA>
basic_string<charT, ST, SA>
regex_replace(const basic_string<charT, ST, SA>& s,
const basic_regex<charT, traits>& e,
const charT* fmt,
regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs an empty string result of type basic_string<charT, ST, SA> and calls:
regex_replace(back_inserter(result), s.begin(), s.end(), e, fmt, flags);

Returns: result.

§ 30.11.4
Effects: Constructs an empty string result of type basic_string<charT> and calls:

\[
\text{regex_replace(back_inserter(result), s, s + char_traits<charT>::length(s), e, fmt, flags)};
\]

Returns: result.

30.12 Regular expression iterators

30.12.1 Class template regex_iterator

The class template regex_iterator is an iterator adaptor. It represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence. A regex_iterator uses regex_search to find successive regular expression matches within the sequence from which it was constructed. After the iterator is constructed, and every time operator++ is used, the iterator finds and stores a value of match_results<BidirectionalIterator>. If the end of the sequence is reached (regex_search returns false), the iterator becomes equal to the end-of-sequence iterator value. The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator* on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>& is returned. The result of operator-> on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>* is returned. It is impossible to store things into regex_iterators. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

namespace std {
    template<class BidirectionalIterator,  
    class charT = typename iterator_traits<BidirectionalIterator>::value_type,  
    class traits = regex_traits<charT>>
    class regex_iterator {
    public:
        using regex_type = basic_regex<charT, traits>;
        using iterator_category = forward_iterator_tag;
        using value_type = match_results<BidirectionalIterator>;
        using difference_type = ptrdiff_t;
        using pointer = const value_type*;
        using reference = const value_type&;
        regex_iterator();
        regex_iterator(BidirectionalIterator a, BidirectionalIterator b,  
            const regex_type& re,  
            regex_constants::match_flag_type m = regex_constants::match_default);
        regex_iterator(BidirectionalIterator, BidirectionalIterator,  
            const regex_type&&,  
            regex_constants::match_flag_type = regex_constants::match_default) = delete;
        regex_iterator(const regex_iterator&);
        regex_iterator& operator=(const regex_iterator&);
        bool operator==(const regex_iterator&);
        bool operator!=(const regex_iterator&); const;
        const value_type* operator->() const;
        regex_iterator& operator++();
        regex_iterator operator++(int);
    private:
        BidirectionalIterator begin; // exposition only
        BidirectionalIterator end; // exposition only
        const regex_type* pregex; // exposition only
        regex_constants::match_flag_type flags; // exposition only
        match_results<BidirectionalIterator> match; // exposition only
    };
}

2 An object of type regex_iterator that is not an end-of-sequence iterator holds a zero-length match if match[0].matched == true and match[0].first == match[0].second. [Note: For example, this can occur when the part of the regular expression that matched consists only of an assertion (such as `^\.`), `'\$'`, `'\b'`, `'\B'`). — end note]
30.12.1.1 Constructors

regex_iterator();

Effects: Constructs an end-of-sequence iterator.

regex_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, regex_constants::match_flag_type m = regex_constants::match_default);

Effects: Initializes begin and end to a and b, respectively, sets pregex to addressof(re), sets flags to m, then calls regex_search(begin, end, match, *pregex, flags). If this call returns false the constructor sets *this to the end-of-sequence iterator.

30.12.1.2 Comparisons

bool operator==(const regex_iterator& right) const;

Returns: true if *this and right are both end-of-sequence iterators or if the following conditions all hold:

1. begin == right.begin,
2. end == right.end,
3. pregex == right.pregex,
4. flags == right.flags, and
5. match[0] == right.match[0]; otherwise false.

30.12.1.3 Indirection

const value_type& operator*() const;

Returns: match.

const value_type* operator->() const;

Returns: addressof(match).

30.12.1.4 Increment

regex_iterator& operator++();

Effects: Constructs a local variable start of type BidirectionalIterator and initializes it with the value of match[0].second.

1. If the iterator holds a zero-length match and start == end the operator sets *this to the end-of-sequence iterator and returns *this.
2. Otherwise, if the iterator holds a zero-length match, the operator calls:
   regex_search(start, end, match, *pregex, flags | regex_constants::match_not_null | regex_constants::match_continuous)
   If the call returns true the operator returns *this. Otherwise the operator increments start and continues as if the most recent match was not a zero-length match.
3. If the most recent match was not a zero-length match, the operator sets flags to flags | regex_constants::match_prev_avail and calls regex_search(start, end, match, *pregex, flags). If the call returns false the iterator sets *this to the end-of-sequence iterator. The iterator then returns *this.
4. In all cases in which the call to regex_search returns true, match.prefix().first shall be equal to the previous value of match[0].second, and for each index i in the half-open range [0, match.size()) for which match[i].matched is true, match.position(i) shall return distance(begin, match[i].first).
   [Note: This means that match.position(i) gives the offset from the beginning of the target sequence, which is often not the same as the offset from the sequence passed in the call to regex_search. — end note]
5. It is unspecified how the implementation makes these adjustments.
6. [Note: This means that a compiler may call an implementation-specific search function, in which case a program-defined specialization of regex_search will not be called. — end note]
Effects: As if by:

```
regex_iterator tmp = *this;
++(*this);
return tmp;
```

### 30.12.2 Class template regex_token_iterator [re.tokiter]

The class template `regex_token_iterator` is an iterator adaptor; that is to say it represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence, and presenting one or more sub-expressions for each match found. Each position enumerated by the iterator is a `sub_match` class template instance that represents what matched a particular sub-expression within the regular expression.

When class `regex_token_iterator` is used to enumerate a single sub-expression with index -1 the iterator performs field splitting: that is to say it enumerates one sub-expression for each section of the character container sequence that does not match the regular expression specified.

After it is constructed, the iterator finds and stores a value `regex_iterator<BidirectionalIterator> position` and sets the internal count `N` to zero. It also maintains a sequence `subs` which contains a list of the sub-expressions which will be enumerated. Every time `operator++` is used the count `N` is incremented; if `N` exceeds or equals `subs.size()`, then the iterator increments member `position` and sets count `N` to zero.

If the end of sequence is reached (position is equal to the end of sequence iterator), the iterator becomes equal to the end-of-sequence iterator value, unless the sub-expression being enumerated has index -1, in which case the iterator enumerates one last sub-expression that contains all the characters from the end of the last regular expression match to the end of the input sequence being enumerated, provided that this would not be an empty sub-expression.

The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of `operator*` on an end-of-sequence iterator is not defined. For any other iterator value a `const sub_match<BidirectionalIterator>` is returned. The result of `operator->` on an end-of-sequence iterator is not defined. For any other iterator value a `const sub_match<BidirectionalIterator>*` is returned.

It is impossible to store things into `regex_token_iterator`s. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.
A suffix iterator is a regex_token_iterator object that points to a final sequence of characters at the end of the target sequence. In a suffix iterator the member result holds a pointer to the data member suffix, the value of the member suffix.match is true, suffix.first points to the beginning of the final sequence, and suffix.second points to the end of the final sequence.

[Note: For a suffix iterator, data member suffix.first is the same as the end of the last match found, and suffix.second is the same as the end of the target sequence. — end note]

The current match is (*position).prefix() if subs[N] == -1, or (*position)[subs[N]] for any other value of subs[N].

30.12.2.1 Constructors

regex_token_iterator();

Effects: Constructs the end-of-sequence iterator.
regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, int submatch = 0, regex_constants::match_flag_type m = regex_constants::match_default);

regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, const vector<int>& submatches, regex_constants::match_flag_type m = regex_constants::match_default);

regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, initializer_list<int> submatches, regex_constants::match_flag_type m = regex_constants::match_default);

template<size_t N>
regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, const int (&submatches)[N], regex_constants::match_flag_type m = regex_constants::match_default);

2 Preconditions: Each of the initialization values of submatches is >= -1.

3 Effects: The first constructor initializes the member subs to hold the single value submatch. The second, third, and fourth constructors initialize the member subs to hold a copy of the sequence of integer values pointed to by the iterator range [begin(submatches), end(submatches)).

4 Each constructor then sets N to 0, and position to position_iterator(a, b, re, m). If position is not an end-of-sequence iterator the constructor sets result to the address of the current match. Otherwise if any of the values stored in subs is equal to -1 the constructor sets *this to a suffix iterator that points to the range [a, b), otherwise the constructor sets *this to an end-of-sequence iterator.

30.12.2.2 Comparisons [re.tokiter.comp]

bool operator==(const regex_token_iterator& right) const;

1 Returns: true if *this and right are both end-of-sequence iterators, or if *this and right are both suffix iterators and suffix == right.suffix; otherwise returns false if *this or right is an end-of-sequence iterator or a suffix iterator. Otherwise returns true if position == right.position, N == right.N, and subs == right.subs. Otherwise returns false.

30.12.2.3 Indirection [re.tokiter.deref]

const value_type& operator*() const;

1 Returns: *result.

const value_type* operator->() const;

2 Returns: result.

30.12.2.4 Increment [re.tokiter.incr]

regex_token_iterator& operator++();

1 Effects: Constructs a local variable prev of type position_iterator, initialized with the value of position. If *this is a suffix iterator, sets *this to an end-of-sequence iterator.

2 Otherwise, if N + 1 < subs.size(), increments N and sets result to the address of the current match.

3 Otherwise, sets N to 0 and increments position. If position is not an end-of-sequence iterator the operator sets result to the address of the current match.

4 Otherwise, if any of the values stored in subs is equal to -1 and prev->suffix().length() is not 0 the operator sets *this to a suffix iterator that points to the range [prev->suffix().first, prev->suffix().second).

5 Otherwise, sets *this to an end-of-sequence iterator.

6 Returns: *this
regex_token_iterator& operator++(int);

Effects: Constructs a copy tmp of *this, then calls ++(*this).

Returns: tmp.

30.13 Modified ECMAScript regular expression grammar [re.grammar]

The regular expression grammar recognized by basic_regex objects constructed with the ECMAScript flag is that specified by ECMA-262, except as specified below.

Objects of type specialization of basic_regex store within themselves a default-constructed instance of their traits template parameter, henceforth referred to as traits_inst. This traits_inst object is used to support localization of the regular expression; basic_regex member functions shall not call any locale dependent C or C++ API, including the formatted string input functions. Instead they shall call the appropriate traits member function to achieve the required effect.

The following productions within the ECMAScript grammar are modified as follows:

ClassAtom::
  -
  ClassAtomNoDash
  ClassAtomExClass
  ClassAtomCollatingElement
  ClassAtomEquivalence

IdentityEscape::
  SourceCharacter but not c

The following new productions are then added:

ClassAtomExClass ::= 
  [.:ClassName:]  
ClassAtomCollatingElement ::= 
  [.ClassName.]  
ClassAtomEquivalence ::= 
  [=ClassName=]  

ClassName::
  ClassNameCharacter
  ClassNameCharacter ClassName

ClassNameCharacter::
  SourceCharacter but not one of . or = or :

The productions ClassAtomExClass, ClassAtomCollatingElement and ClassAtomEquivalence provide functionality equivalent to that of the same features in regular expressions in POSIX.

The regular expression grammar may be modified by any regex_constants::syntax_option_type flags specified when constructing an object of type specialization of basic_regex according to the rules in Table 136.

A ClassName production, when used in a ClassAtomExClass, is not valid if traits_inst.lookup_classname returns zero for that name. The names recognized as valid ClassNames are determined by the type of the traits class, but at least the following names shall be recognized: alnum, alpha, blank, cntrl, digit, graph, lower, print, punct, space, upper, xdigit, d, s, w. In addition the following expressions shall be equivalent:

\d and [[:digit:]]
\D and [^[:digit:]]
\s and [[:space:]]
\S and [^[:space:]]
\w and [_.:alnum:]  
\W and [^_.:alnum:]  

A ClassName production when used in a ClassAtomCollatingElement production is not valid if the value returned by traits_inst.lookup_collatename for that name is an empty string.

§ 30.13
The results from multiple calls to `traits_inst.lookup_classname` can be bitwise OR'ed together and subsequently passed to `traits_inst.isctype`.

A `ClassName` production when used in a `ClassAtomEquivalence` production is not valid if the value returned by `traits_inst.lookup_collatename` for that name is an empty string or if the value returned by `traits_inst.transform_primary` for the result of the call to `traits_inst.lookup_collatename` is an empty string.

When the sequence of characters being transformed to a finite state machine contains an invalid class name the translator shall throw an exception object of type `regex_error`.

If the `CV` of a `UnicodeEscapeSequence` is greater than the largest value that can be held in an object of type `charT` the translator shall throw an exception object of type `regex_error`. [Note: This means that values of the form "uxxxx" that do not fit in a character are invalid. — end note]

Where the regular expression grammar requires the conversion of a sequence of characters to an integral value, this is accomplished by calling `traits_inst.value`.

The behavior of the internal finite state machine representation when used to match a sequence of characters is as described in ECMA-262. The behavior is modified according to any `match_flag_type` flags (30.5.2) specified when using the regular expression object in one of the regular expression algorithms (30.11). The behavior is also localized by interaction with the traits class template parameter as follows:

---

### (14.1)
During matching of a regular expression finite state machine against a sequence of characters, two characters `c` and `d` are compared using the following rules:

- if `(flags() & regex_constants::icase)` the two characters are equal if `traits_inst.translate_nocase(c) == traits_inst.translate_nocase(d)`;
- otherwise, if `flags() & regex_constants::collate` the two characters are equal if `traits_inst.translate(c) == traits_inst.translate(d)`;
- otherwise, the two characters are equal if `c == d`.

### (14.2)
During matching of a regular expression finite state machine against a sequence of characters, comparison of a collating element range `c1-c2` against a character `c` is conducted as follows: if `flags() & regex_constants::collate` is false then the character `c` is matched if `c1 <= c && c <= c2`, otherwise `c` is matched in accordance with the following algorithm:

```c++
string_type str1 = string_type(1, flags() & icase ? traits_inst.translate_nocase(c1) : traits_inst.translate(c1));
string_type str2 = string_type(1, flags() & icase ? traits_inst.translate_nocase(c2) : traits_inst.translate(c2));
string_type str = string_type(1, flags() & icase ? traits_inst.translate_nocase(c) : traits_inst.translate(c));
return traits_inst.transform(str1.begin(), str1.end()) <= traits_inst.transform(str.begin(), str.end()) && traits_inst.transform(str.begin(), str.end()) <= traits_inst.transform(str2.begin(), str2.end());
```

### (14.3)
During matching of a regular expression finite state machine against a sequence of characters, testing whether a collating element is a member of a primary equivalence class is conducted by first converting the collating element and the equivalence class to sort keys using `traits::transform_primary`, and then comparing the sort keys for equality.

### (14.4)
During matching of a regular expression finite state machine against a sequence of characters, a character `c` is a member of a character class designated by an iterator range `[first, last)` if `traits_inst.isctype(c, traits_inst.lookup_classname(first, last, flags() & icase))` is true.

§ 30.13
31  Atomic operations library

31.1  General

This Clause describes components for fine-grained atomic access. This access is provided via operations on atomic objects.

The following subclauses describe atomics requirements and components for types and operations, as summarized in Table 143.

Table 143: Atomics library summary

// 31.11, fences
extern "C" void atomic_thread_fence(memory_order) noexcept;
extern "C" void atomic_signal_fence(memory_order) noexcept;
There is a single total order \( S \) on all \( \text{memory\_order::seq\_cst} \) operations, including fences, that satisfies the following constraints. First, if \( A \) and \( B \) are \( \text{memory\_order::seq\_cst} \) operations and \( A \) strongly happens before \( B \), then \( A \) precedes \( B \) in \( S \). Second, for every pair of atomic operations \( A \) and \( B \) on an object \( M \), where \( A \) is coherence-ordered before \( B \), the following four conditions are required to be satisfied by \( S \):

1. If \( A \) and \( B \) are both \( \text{memory\_order::seq\_cst} \) operations, then \( A \) precedes \( B \) in \( S \); and
2. If \( A \) is a \( \text{memory\_order::seq\_cst} \) operation and \( B \) happens before a \( \text{memory\_order::seq\_cst} \) fence \( Y \), then \( A \) precedes \( Y \) in \( S \); and
3. If a \( \text{memory\_order::seq\_cst} \) fence \( X \) happens before \( A \) and \( B \) is a \( \text{memory\_order::seq\_cst} \) operation, then \( X \) precedes \( B \) in \( S \); and
4. If a \( \text{memory\_order::seq\_cst} \) fence \( X \) happens before \( A \) and \( B \) happens before a \( \text{memory\_order::seq\_cst} \) fence \( Y \), then \( X \) precedes \( Y \) in \( S \).

[Note: This definition ensures that \( S \) is consistent with the modification order of any atomic object \( M \). It also ensures that a \( \text{memory\_order::seq\_cst} \) load \( A \) of \( M \) gets its value either from the last modification of \( M \) that precedes \( A \) in \( S \) or from some non-\( \text{memory\_order::seq\_cst} \) modification of \( M \) that does not happen before any modification of \( M \) that precedes \( A \) in \( S \).—end note]

[Note: We do not require that \( S \) be consistent with “happens before” (6.9.2.1). This allows more efficient implementation of \( \text{memory\_order::acquire} \) and \( \text{memory\_order::release} \) on some machine architectures. It can produce surprising results when these are mixed with \( \text{memory\_order::seq\_cst} \) accesses. —end note]

[Note: \( \text{memory\_order::seq\_cst} \) ensures sequential consistency only for a program that is free of data races and uses exclusively \( \text{memory\_order::seq\_cst} \) atomic operations. Any use of weaker ordering will invalidate this guarantee unless extreme care is used. In many cases, \( \text{memory\_order::seq\_cst} \) atomic operations are reorderable with respect to other atomic operations performed by the same thread. —end note]

Implementations should ensure that no “out-of-thin-air” values are computed that circularly depend on their own computation.

[Note: For example, with \( x \) and \( y \) initially zero,

```c
// Thread 1:
int r1 = y.load(memory_order::relaxed);
x.store(r1, memory_order::relaxed);

// Thread 2:
int r2 = x.load(memory_order::relaxed);
y.store(r2, memory_order::relaxed);
```

should not produce \( r1 == r2 == 42 \), since the store of 42 to \( y \) is only possible if the store to \( x \) stores 42, which circularly depends on the store to \( y \) storing 42. Note that without this restriction, such an execution is possible. —end note]

[Note: The recommendation similarly disallows \( r1 == r2 == 42 \) in the following example, with \( x \) and \( y \) again initially zero:

```c
// Thread 1:
int r1 = y.load(memory_order::relaxed);
x.store(r1, memory_order::relaxed);

// Thread 2:
int r2 = x.load(memory_order::relaxed);
y.store(r2, memory_order::relaxed);
```
Thread 1:
   r1 = x.load(memory_order::relaxed);
   if (r1 == 42) y.store(42, memory_order::relaxed);

Thread 2:
   r2 = y.load(memory_order::relaxed);
   if (r2 == 42) x.store(42, memory_order::relaxed);
— end note

Atomic read-modify-write operations shall always read the last value (in the modification order) written before the write associated with the read-modify-write operation.

Implementations should make atomic stores visible to atomic loads within a reasonable amount of time.

template<class T>
   T kill_dependency(T y) noexcept;

Effects: The argument does not carry a dependency to the return value (6.9.2).

Returns: y.

31.5 Lock-free property [atomics.lockfree]

The ATOMIC_..._LOCK_FREE macros indicate the lock-free property of the corresponding atomic types, with the signed and unsigned variants grouped together. The properties also apply to the corresponding (partial) specializations of the atomic template. A value of 0 indicates that the types are never lock-free. A value of 1 indicates that the types are sometimes lock-free. A value of 2 indicates that the types are always lock-free.

At least one signed integral specialization of the atomic template, along with the specialization for the corresponding unsigned type (6.8.1), is always lock-free. [Note: This requirement is optional in freestanding implementations (16.5.1.3). — end note]

The function atomic_is_lock_free (31.8.1) indicates whether the object is lock-free. In any given program execution, the result of the lock-free query shall be consistent for all pointers of the same type.

Atomic operations that are not lock-free are considered to potentially block (6.9.2.2).

[Note: Operations that are lock-free should also be address-free. That is, atomic operations on the same memory location via two different addresses will communicate atomically. The implementation should not depend on any per-process state. This restriction enables communication by memory that is mapped into a process more than once and by memory that is shared between two processes. — end note]

31.6 Waiting and notifying [atomics.wait]

Atomic waiting operations and atomic notifying operations provide a mechanism to wait for the value of an atomic object to change more efficiently than can be achieved with polling. An atomic waiting operation may block until it is unblocked by an atomic notifying operation, according to each function’s effects. [Note: Programs are not guaranteed to observe transient atomic values, an issue known as the A-B-A problem, resulting in continued blocking if a condition is only temporarily met. — end note]

[Note: The following functions are atomic waiting operations:
   (2.1) atomic<T>::wait,
   (2.2) atomic_flag::wait,
   (2.3) atomic_wait and atomic_wait_explicit,
   (2.4) atomic_flag_wait and atomic_flag_wait_explicit, and

§ 31.6 1494
atomic_ref<T>::wait.

end note]

Note: The following functions are atomic notifying operations:

- atomic<T>::notify_one and atomic<T>::notify_all,
- atomic_flag::notify_one and atomic_flag::notify_all,
- atomic_notify_one and atomic_notify_all,
- atomic_flag_notify_one and atomic_flag_notify_all, and
- atomic_ref<T>::notify_one and atomic_ref<T>::notify_all.

end note]

A call to an atomic waiting operation on an atomic object \( M \) is eligible to be unblocked by a call to an atomic notifying operation on \( M \) if there exist side effects \( X \) and \( Y \) on \( M \) such that:

- the atomic waiting operation has blocked after observing the result of \( X \),
- \( X \) precedes \( Y \) in the modification order of \( M \), and
- \( Y \) happens before the call to the atomic notifying operation.

### 31.7 Class template atomic_ref

```cpp
namespace std {
    template<class T> struct atomic_ref {
        private:
            T* ptr;  // exposition only
        public:
            using value_type = T;
            static constexpr size_t required_alignment = implementation-defined;
            static constexpr bool is_always_lock_free = implementation-defined;
            bool is_lock_free() const noexcept;
            explicit atomic_ref(T&);
            atomic_ref(const atomic_ref&) noexcept;
            atomic_ref& operator=(const atomic_ref&) = delete;
            void store(T, memory_order = memory_order::seq_cst) const noexcept;
            T operator=(T) const noexcept;
            T load(memory_order = memory_order::seq_cst) const noexcept;
            operator T() const noexcept;
            T exchange(T, memory_order = memory_order::seq_cst) const noexcept;
            bool compare_exchange_weak(T&, T,
                memory_order, memory_order) const noexcept;
            bool compare_exchange_strong(T&, T,
                memory_order, memory_order) const noexcept;
            bool compare_exchange_weak(T&, T,
                memory_order = memory_order::seq_cst) const noexcept;
            bool compare_exchange_strong(T&, T,
                memory_order = memory_order::seq_cst) const noexcept;
            void wait(T, memory_order = memory_order::seq_cst) const noexcept;
            void notify_one() const noexcept;
            void notify_all() const noexcept;
    };
}
```

1. An atomic_ref object applies atomic operations (31.1) to the object referenced by *ptr such that, for the lifetime (6.7.3) of the atomic_ref object, the object referenced by *ptr is an atomic object (6.9.2.1).
2. The program is ill-formed if is_trivially_copyable_v<T> is false.
3. The lifetime (6.7.3) of an object referenced by *ptr shall exceed the lifetime of all atomicRefs that reference the object. While any atomic_ref instances exist that reference the *ptr object, all accesses to that object shall
exclusively occur through those atomic_ref instances. No subobject of the object referenced by atomic_ref shall be concurrently referenced by any other atomic_ref object.

Atomic operations applied to an object through a referencing atomic_ref are atomic with respect to atomic operations applied through any other atomic_ref referencing the same object. [Note: Atomic operations or the atomic_ref constructor could acquire a shared resource, such as a lock associated with the referenced object, to enable atomic operations to be applied to the referenced object. — end note]

31.7.1 Operations

static constexpr size_t required_alignment;
1
The alignment required for an object to be referenced by an atomic reference, which is at least alignof(T).

[Note: Hardware could require an object referenced by an atomic_ref to have stricter alignment (6.7.6) than other objects of type T. Further, whether operations on an atomic_ref are lock-free could depend on the alignment of the referenced object. For example, lock-free operations on std::complex<double> could be supported only if aligned to 2*alignof(double). — end note]

static constexpr bool is_always_lock_free;
2
The static data member is_always_lock_free is true if the atomic_ref type’s operations are always lock-free, and false otherwise.

bool is_lock_free() const noexcept;
3
Returns: true if operations on all objects of the type atomic_ref<T> are lock-free, false otherwise.

atomic_ref(T& obj);
4
Preconditions: The referenced object is aligned to required_alignment.
Postconditions: *this references obj.
Throws: Nothing.

atomic_ref(const atomic_ref& ref) noexcept;
5
Postconditions: *this references the object referenced by ref.

void store(T desired, memory_order order = memory_order::seq_cst) const noexcept;
6
Preconditions: The order argument is neither memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.
Effects: Atomically replaces the value referenced by *ptr with the value of desired. Memory is affected according to the value of order.

T operator=(T desired) const noexcept;    
Effects: Equivalent to:
        store(desired);
        return desired;

T load(memory_order order = memory_order::seq_cst) const noexcept;
8
Preconditions: The order argument is neither memory_order::release nor memory_order::acq_rel.
Effects: Memory is affected according to the value of order.
Returns: Atomically returns the value referenced by *ptr.

operator T() const noexcept;
9
Effects: Equivalent to: return load();

T exchange(T desired, memory_order order = memory_order::seq_cst) const noexcept;
10 Effects: Atomically replaces the value referenced by *ptr with desired. Memory is affected according to the value of order. This operation is an atomic read-modify-write operation (6.9.2).
Returns: Atomically returns the value referenced by *ptr immediately before the effects.
bool compare_exchange_weak(T& expected, T desired, 
memory_order success, memory_order failure) const noexcept;

bool compare_exchange_strong(T& expected, T desired, 
memory_order success, memory_order failure) const noexcept;

bool compare_exchange_weak(T& expected, T desired, 
memory_order order = memory_order::seq_cst) const noexcept;

bool compare_exchange_strong(T& expected, T desired, 
memory_order order = memory_order::seq_cst) const noexcept;

18 Preconditions: The failure argument is neither memory_order::release nor memory_order::acq_rel.

19 Effects: Retrieves the value in expected. It then atomically compares the value representation of the value referenced by *ptr for equality with that previously retrieved from expected, and if true, replaces the value referenced by *ptr with that in desired. If and only if the comparison is true, memory is affected according to the value of success, and if the comparison is false, memory is affected according to the value of failure. When only one memory_order argument is supplied, the value of success is order, and the value of failure is order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed. If and only if the comparison is false then, after the atomic operation, the value in expected is replaced by the value read from the value referenced by *ptr during the atomic comparison. If the operation returns true, these operations are atomic read-modify-write operations (6.9.2.1) on the value referenced by *ptr. Otherwise, these operations are atomic load operations on that memory.

20 Returns: The result of the comparison.

21 Remarks: A weak compare-and-exchange operation may fail spuriously. That is, even when the contents of memory referred to by expected and ptr are equal, it may return false and store back to expected the same memory contents that were originally there. [Note: This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop. When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. — end note]

void wait(T old, memory_order order = memory_order::seq_cst) const noexcept;

22 Preconditions: order is neither memory_order::release nor memory_order::acq_rel.

23 Effects: Repeatedly performs the following steps, in order:

(23.1) Evaluates load(order) and compares its value representation for equality against that of old.

(23.2) If they compare unequal, returns.

(23.3) Blocks until it is unblocked by an atomic notifying operation or is unblocked spuriously.

24 Remarks: This function is an atomic waiting operation (31.6) on atomic object *ptr.

void notify_one() const noexcept;

25 Effects: Unblocks the execution of at least one atomic waiting operation on *ptr that is eligible to be unblocked (31.6) by this call, if any such atomic waiting operations exist.

26 Remarks: This function is an atomic notifying operation (31.6) on atomic object *ptr.

void notify_all() const noexcept;

27 Effects: Unblocks the execution of all atomic waiting operations on *ptr that are eligible to be unblocked (31.6) by this call.

28 Remarks: This function is an atomic notifying operation (31.6) on atomic object *ptr.

31.7.2 Specializations for integral types [atomics.ref.int]

There are specializations of the atomic_ref class template for the integral types char, signed char, unsigned char, short, unsigned short, int, unsigned int, long, unsigned long, long long, unsigned long long, char8_t, char16_t, char32_t, wchar_t, and any other types needed by the typedefs in the header <cstdint>
For each such type \texttt{integral}, the specialization \texttt{atomic_ref<integral>} provides additional atomic operations appropriate to integral types. [Note: The specialization \texttt{atomic_ref<bool>} uses the primary template (31.7). — end note]

```cpp
namespace std {
    template<> struct atomic_ref<integral> {
        integral* ptr; // exposition only
    
    public:
        using value_type = integral;
        using difference_type = value_type;
        static constexpr size_t required_alignment = implementation-defined;
        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const noexcept;
        explicit atomic_ref(integral&);
        atomic_ref(const atomic_ref&) noexcept;
        atomic_ref& operator=(const atomic_ref&) = delete;
        void store(integral, memory_order = memory_order::seq_cst) const noexcept;
        integral operator=(integral) const noexcept;
        integral operator++(int) const noexcept;
        integral operator--(int) const noexcept;
        integral operator++() const noexcept;
        integral operator--() const noexcept;
        integral operator+= (integral) const noexcept;
        integral operator-= (integral) const noexcept;
        integral operator&= (integral) const noexcept;
        integral operator|= (integral) const noexcept;
        integral operator^= (integral) const noexcept;
        integral operator++(int) const noexcept;
        integral operator== (integral) const noexcept;
        integral operator!= (integral) const noexcept;
        integral operator&= (integral) const noexcept;
        integral operator|= (integral) const noexcept;
        integral operator^= (integral) const noexcept;
        integral operator+= (integral) const noexcept;
        integral operator-= (integral) const noexcept;
        integral operator&= (integral) const noexcept;
        integral operator|= (integral) const noexcept;
        integral operator^= (integral) const noexcept;
        integral operator++(int) const noexcept;
        integral operator== (integral) const noexcept;
        integral operator!= (integral) const noexcept;
        integral operator&= (integral) const noexcept;
        integral operator|= (integral) const noexcept;
        integral operator^= (integral) const noexcept;

        integral exchange(integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        bool compare_exchange_weak(integral&, integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        bool compare_exchange_strong(integral&, integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        bool compare_exchange_strong(integral&, integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        bool compare_exchange_weak(integral&, integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        bool compare_exchange_strong(integral&, integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        integral fetch_add(integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        integral fetch_sub(integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        integral fetch_and(integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        integral fetch_or(integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        integral fetch_xor(integral, 
            memory_order = memory_order::seq_cst) const noexcept;

        void wait(integral, 
            memory_order = memory_order::seq_cst) const noexcept;
        void notify_one() const noexcept;
        void notify_all() const noexcept;
    }
}
```

Descriptions are provided below only for members that differ from the primary template.
The following operations perform arithmetic computations. The key, operator, and computation correspondence is identified in Table 144.

```cpp
integral fetch_key(integral operand, memory_order order = memory_order::seq_cst) const noexcept;
```

**Effects:** Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2.1).

**Returns:** Atomically, the value referenced by *ptr immediately before the effects.

**Remarks:** For signed integer types, the result is as if the object value and parameters were converted to their corresponding unsigned types, the computation performed on those types, and the result converted back to the signed type. [Note: There are no undefined results arising from the computation. — end note]

```cpp
integral operator op=(integral operand) const noexcept;
```

**Effects:** Equivalent to: return fetch_key(operand) op operand;

### 31.7.3 Specializations for floating-point types [atomics.ref.float]

There are specializations of the atomic_ref class template for the floating-point types float, double, and long double. For each such type `floating-point`, the specialization `atomic_ref<floating-point>` provides additional atomic operations appropriate to floating-point types.

```cpp
namespace std {
    template<> struct atomic_ref<floating-point> { 
       private:
           floating-point* ptr; // exposition only
       public:
          using value_type = floating-point;
          using difference_type = value_type;
          static constexpr size_t required_alignment = implementation-defined;
          static constexpr bool is_always_lock_free = implementation-defined;
          bool is_lock_free() const noexcept;
          explicit atomic_ref(floating-point&);
          atomic_ref(const atomic_ref&) noexcept;
          atomic_ref& operator=(const atomic_ref&) = delete;
          void store(floating-point, memory_order = memory_order::seq_cst) const noexcept;
          floating-point operator=(floating-point) const noexcept;
          floating-point load(memory_order = memory_order::seq_cst) const noexcept;
          operator floating-point() const noexcept;
          floating-point exchange(floating-point,
                                      memory_order = memory_order::seq_cst) const noexcept;
          bool compare_exchange_weak(floating-point&, floating-point,
                                      memory_order, memory_order) const noexcept;
          bool compare_exchange_strong(floating-point&, floating-point,
                                      memory_order, memory_order) const noexcept;
          bool compare_exchange_weak(floating-point&, floating-point,
                                      memory_order = memory_order::seq_cst) const noexcept;
          bool compare_exchange_strong(floating-point&, floating-point,
                                      memory_order = memory_order::seq_cst) const noexcept;
          floating-point fetch_add(floating-point,
                                      memory_order = memory_order::seq_cst) const noexcept;
          floating-point fetch_sub(floating-point,
                                      memory_order = memory_order::seq_cst) const noexcept;
          floating-point operator+=(floating-point) const noexcept;
          floating-point operator-=(floating-point) const noexcept;
          void wait(floating-point, memory_order = memory_order::seq_cst) const noexcept;
          void notify_one() const noexcept;
    }
}
```
void notify_all() const noexcept;
};

Descriptions are provided below only for members that differ from the primary template.

The following operations perform arithmetic computations. The key, operator, and computation correspondence are identified in Table 144.

float floating-point fetch_key(float operand,

  memory_order order = memory_order::seq_cst) const noexcept;

Effects: Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2.1).

Returns: Atomically, the value referenced by *ptr immediately before the effects.

Remarks: If the result is not a representable value for its type (7.1), the result is unspecified, but the operations otherwise have no undefined behavior. Atomic arithmetic operations on floating-point should conform to the std::numeric_limits< |floating-point| > traits associated with the floating-point type (17.3.3). The floating-point environment (26.3) for atomic arithmetic operations on floating-point may be different than the calling thread’s floating-point environment.

float operator op=(float operand) const noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

§ 31.7.4 Partial specialization for pointers

namespace std {
  template<class T> struct atomic_ref<T*> {
    private:
      T** ptr; // exposition only
    public:
      using value_type = T*;
      using difference_type = ptrdiff_t;
      static constexpr size_t required_alignment = implementation-defined;
      static constexpr bool is_always_lock_free = implementation-defined;
      bool is_lock_free() const noexcept;
      explicit atomic_ref(T*);
      atomic_ref(const atomic_ref&) noexcept;
      atomic_ref& operator=(const atomic_ref&) = delete;
      void store(T*, memory_order = memory_order::seq_cst) const noexcept;
      T* operator=(T*) const noexcept;
      T* load(memory_order = memory_order::seq_cst) const noexcept;
      operator T*() const noexcept;
      T* exchange(T*, memory_order = memory_order::seq_cst) const noexcept;
      bool compare_exchange_weak(T*, T*,
        memory_order, memory_order) const noexcept;
      bool compare_exchange_strong(T*, T*,
        memory_order, memory_order) const noexcept;
      bool compare_exchange_weak(T*, T*,
        memory_order = memory_order::seq_cst) const noexcept;
      bool compare_exchange_strong(T*, T*,
        memory_order = memory_order::seq_cst) const noexcept;
      T* fetch_add(difference_type, memory_order = memory_order::seq_cst) const noexcept;
      T* fetch_sub(difference_type, memory_order = memory_order::seq_cst) const noexcept;
      T* operator++(int) const noexcept;
      T* operator--(int) const noexcept;
      T* operator++() const noexcept;
  };
T* operator--() const noexcept;
T* operator+=(difference_type) const noexcept;
T* operator-=(difference_type) const noexcept;

void wait(T*, memory_order = memory_order::seq_cst) const noexcept;
void notify_one() const noexcept;
void notify_all() const noexcept;
};
}

1 Descriptions are provided below only for members that differ from the primary template.

2 The following operations perform arithmetic computations. The key, operator, and computation correspondence is identified in Table 145.

3 T* fetch_key(difference_type operand, memory_order order = memory_order::seq_cst) const noexcept;

4 Mandates: T is a complete object type.

5 Effects: Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2.1).

6 Returns: Atomically, the value referenced by *ptr immediately before the effects.

7 Remarks: The result may be an undefined address, but the operations otherwise have no undefined behavior.

T* operator op=(difference_type operand) const noexcept;

7 Effects: Equivalent to: return fetch_key(operand) op operand;

31.7.5 Member operators common to integers and pointers to objects [atomics.ref.memop]

value_type operator++(int) const noexcept;

1 Effects: Equivalent to: return fetch_add(1);

value_type operator--(int) const noexcept;

2 Effects: Equivalent to: return fetch_sub(1);

value_type operator++() const noexcept;

3 Effects: Equivalent to: return fetch_add(1) + 1;

value_type operator--() const noexcept;

4 Effects: Equivalent to: return fetch_sub(1) - 1;

31.8 Class template atomic [atomics.types.generic]

namespace std {
    template<class T> struct atomic {
        using value_type = T;

        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;

        // 31.8.1, operations on atomic types
        constexpr atomic() noexcept(is_nothrow_default_constructible_v<T>);
        constexpr atomic(T) noexcept;
        atomic(const atomic&) = delete;
        atomic& operator=(const atomic&) = delete;
        atomic& operator=(const atomic&) volatile = delete;

        T load(memory_order = memory_order::seq_cst) const volatile noexcept;
        T load(memory_order = memory_order::seq_cst) const noexcept;
        operator T() const volatile noexcept;
        operator T() const noexcept;
        void store(T, memory_order = memory_order::seq_cst) volatile noexcept;
    };
}
void store(T, memory_order = memory_order::seq_cst) noexcept;
T operator=(T) volatile noexcept;
T operator=(T) noexcept;
T exchange(T, memory_order = memory_order::seq_cst) volatile noexcept;
T exchange(T, memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_weak(T&, T, memory_order, memory_order) volatile noexcept;
bool compare_exchange_weak(T&, T, memory_order, memory_order) noexcept;
bool compare_exchange_strong(T&, T, memory_order, memory_order) volatile noexcept;
bool compare_exchange_strong(T&, T, memory_order, memory_order) noexcept;
bool compare_exchange_weak(T&, T, memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_weak(T&, T, memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(T&, T, memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(T&, T, memory_order = memory_order::seq_cst) noexcept;
void wait(T, memory_order = memory_order::seq_cst) const volatile noexcept;
void wait(T, memory_order = memory_order::seq_cst) const noexcept;
void notify_one() volatile noexcept;
void notify_one() noexcept;
void notify_all() volatile noexcept;
void notify_all() noexcept;
}

1 The template argument for \( T \) shall meet the `Cpp17CopyConstructible` and `Cpp17CopyAssignable` requirements. The program is ill-formed if any of

- is_trivially_copyable_v<T>,
- is_copy_constructible_v<T>,
- is_move_constructible_v<T>,
- is_copyAssignable_v<T>, or
- is_moveAssignable_v<T>

is false. [Note: Type arguments that are not also statically initializable may be difficult to use. — end note]

2 The specialization `atomic<bool>` is a standard-layout struct.

3 [Note: The representation of an atomic specialization need not have the same size and alignment requirement as its corresponding argument type. — end note]

### 31.8.1 Operations on atomic types [atomics.types.operations]

```cpp
constexpr atomic() noexcept(is_nothrow_default_constructible_v<T>);
```

1 *Mandates:* `is_default_constructible_v<T>` is true.

2 *Effects:* Initializes the atomic object with the value of `T()`. Initialization is not an atomic operation (6.9.2).

```cpp
constexpr atomic(T desired) noexcept;
```

3 *Effects:* Initializes the atomic object with the value `desired`. Initialization is not an atomic operation (6.9.2). [Note: It is possible to have an access to an atomic object \( \hat{a} \) race with its construction, for example by communicating the address of the just-constructed object \( \hat{a} \) to another thread via `memory_order::relaxed` operations on a suitable atomic pointer variable, and then immediately accessing \( \hat{a} \) in the receiving thread. This results in undefined behavior. — end note]

```cpp
static constexpr bool is_always_lock_free = implementation-defined;
```

4 The static data member `is_always_lock_free` is true if the atomic type’s operations are always lock-free, and `false` otherwise. [Note: The value of `is_always_lock_free` is consistent with the value of the corresponding `ATOMIC...LOCK_FREE` macro, if defined. — end note]
bool is_lock_free() const noexcept;

Returns: true if the object’s operations are lock-free, false otherwise. [Note: The return value of the is_lock_free member function is consistent with the value of is_always_lock_free for the same type. — end note]

void store(T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
void store(T desired, memory_order order = memory_order::seq_cst) noexcept;

Constraints: For the volatile overload of this function, is_always_lock_free is true.

Preconditions: The order argument is neither memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically replaces the value pointed to by this with the value of desired. Memory is affected according to the value of order.

T operator=(T desired) volatile noexcept;
T operator=(T desired) noexcept;

Constraints: For the volatile overload of this function, is_always_lock_free is true.

Effects: Equivalent to store(desired).

Returns: desired.

T load(memory_order order = memory_order::seq_cst) const volatile noexcept;
T load(memory_order order = memory_order::seq_cst) const noexcept;

Constraints: For the volatile overload of this function, is_always_lock_free is true.

Preconditions: The order argument is neither memory_order::release nor memory_order::acq_rel.

Effects: Memory is affected according to the value of order.

Returns: Atomically returns the value pointed to by this.

T exchange(T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
T exchange(T desired, memory_order order = memory_order::seq_cst) noexcept;

Constraints: For the volatile overload of this function, is_always_lock_free is true.

Effects: Atomically replaces the value pointed to by this with desired. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2).

Returns: Atomically returns the value pointed to by this immediately before the effects.

bool compare_exchange_weak(Tk expected, T desired,
    memory_order success, memory_order failure) volatile noexcept;
bool compare_exchange_weak(Tk expected, T desired,
    memory_order success, memory_order failure) noexcept;

bool compare_exchange_strong(Tk expected, T desired,
    memory_order success, memory_order failure) volatile noexcept;
bool compare_exchange_strong(Tk expected, T desired,
    memory_order success, memory_order failure) noexcept;

bool compare_exchange_weak(Tk expected, T desired,
    memory_order order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_weak(Tk expected, T desired,
    memory_order order = memory_order::seq_cst) noexcept;

bool compare_exchange_strong(Tk expected, T desired,
    memory_order order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(Tk expected, T desired,
    memory_order order = memory_order::seq_cst) noexcept;

Constraints: For the volatile overload of this function, is_always_lock_free is true.

Preconditions: The failure argument is neither memory_order::release nor memory_order::acq_rel.
**Effects:** Retrieves the value in `expected`. It then atomically compares the value representation of the value pointed to by `this` for equality with that previously retrieved from `expected`, and if true, replaces the value pointed to by `this` with that in `desired`. If and only if the comparison is true, memory is affected according to the value of `success`, and if the comparison is false, memory is affected according to the value of `failure`. When only one `memory_order` argument is supplied, the value of `success` is order, and the value of `failure` is order except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`. If and only if the comparison is false then, after the atomic operation, the value in `expected` is replaced by the value pointed to by `this` during the atomic comparison. If the operation returns true, these operations are atomic read-modify-write operations (6.9.2) on the memory pointed to by `this`. Otherwise, these operations are atomic load operations on that memory.

**Returns:** The result of the comparison.

[Note: For example, the effect of `compare_exchange_strong` on objects without padding bits (6.8) is]

```cpp
if (memcmp(this, &expected, sizeof(*this)) == 0)
    memcpy(this, &desired, sizeof(*this));
else
    memcpy(&expected, this, sizeof(*this));
```

— end note]

**Example:** The expected use of the compare-and-exchange operations is as follows. The compare-and-exchange operations will update `expected` when another iteration of the loop is needed.

```cpp
expected = current.load();
do {
    desired = function(expected);
} while (!current.compare_exchange_weak(expected, desired));
```

— end example]

**Example:** Because the expected value is updated only on failure, code releasing the memory containing the expected value on success will work. For example, list head insertion will act atomically and would not introduce a data race in the following code:

```cpp
do {
    p->next = head;      // make new list node point to the current head
} while (!head.compare_exchange_weak(p->next, p)); // try to insert
```

— end example]

Implementations should ensure that weak compare-and-exchange operations do not consistently return `false` unless either the atomic object has value different from `expected` or there are concurrent modifications to the atomic object.

**Remarks:** A weak compare-and-exchange operation may fail spuriously. That is, even when the contents of memory referred to by `expected` and `this` are equal, it may return `false` and store back to `expected` the same memory contents that were originally there. [Note: This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop. When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. — end note]

[Note: Under cases where the `memcpy` and `memcmp` semantics of the compare-and-exchange operations apply, the outcome might be failed comparisons for values that compare equal with `operator==` if the value representation has trap bits or alternate representations of the same value. Notably, on implementations conforming to ISO/IEC/IEEE 60559, floating-point `-0.0` and `+0.0` will not compare equal with `memcpy` but will compare equal with `operator==`, and NaNs with the same payload will compare equal with `memcpy` but will not compare equal with `operator==`. — end note]

```cpp
struct padded {
    char clank = 0x42;
    // Padding here.
    unsigned biff = 0xCODEF0FE;
};
atomic<padded> pad = {};
```
bool zap() {
    padded expected, desired{0, 0};
    return pad.compare_exchange_strong(expected, desired);
}

— end note] [Note: For a union with bits that participate in the value representation of some members but not
others, compare-and-exchange might always fail. This is because such padding bits have an indeterminate
value when they do not participate in the value representation of the active member. As a consequence, the
following code is not guaranteed to ever succeed:

union pony {
    double celestia = 0.;
    short luna;       // padded
};
atomic<pony> princesses = {};

bool party(pony desired) {
    pony expected;
    return princesses.compare_exchange_strong(expected, desired);
}

— end note]

void wait(T old, memory_order order = memory_order::seq_cst) const volatile noexcept;
void wait(T old, memory_order order = memory_order::seq_cst) const noexcept;

29 Preconditions: order is neither memory_order::release nor memory_order::acq_rel.

30 Effects: Repeatedly performs the following steps, in order:

(30.1) — Evaluates load(order) and compares its value representation for equality against that of old.

(30.2) — If they compare unequal, returns.

(30.3) — Blocks until it is unblocked by an atomic notifying operation or is unblocked spuriously.

31 Remarks: This function is an atomic waiting operation (31.6).

void notify_one() volatile noexcept;
void notify_one() noexcept;

32 Effects: Unblocks the execution of at least one atomic waiting operation that is eligible to be unblocked (31.6)
by this call, if any such atomic waiting operations exist.

33 Remarks: This function is an atomic notifying operation (31.6).

void notify_all() volatile noexcept;
void notify_all() noexcept;

34 Effects: Unblocks the execution of all atomic waiting operations that are eligible to be unblocked (31.6) by this
call.

35 Remarks: This function is an atomic notifying operation (31.6).

31.8.2 Specializations for integers [atomics.types.int]

There are specializations of the atomic class template for the integral types char, signed char, unsigned char, short, unsigned short, int, unsigned int, long, unsigned long, long long, unsigned long long, char8_t, char16_t, char32_t, wchar_t, and any other types needed by the typedefs in the header <cstdint>
(17.4.1). For each such type integral, the specialization atomic<integral> provides additional atomic operations
appropriate to integral types. [Note: The specialization atomic<bool> uses the primary template (31.8). — end note]

namespace std {
    template<> struct atomic<integral> {
        using value_type = integral;
        using difference_type = value_type;

        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;

§ 31.8.2

1505
constexpr atomic() noexcept;
cconstexpr atomic(integral) noexcept;
antomic(const atomic&) = delete;
antomic operator=(const atomic&) = delete;

integral fetch_add(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_sub(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_sub(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_and(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_and(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_or(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_or(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_xor(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_xor(integral, memory_order = memory_order::seq_cst) noexcept;

integral operator++(int) volatile noexcept;
integral operator++(int) noexcept;
integral operator--(int) volatile noexcept;
integral operator--(int) noexcept;
integral operator[](int) volatile noexcept;
integral operator[](int) noexcept;
integral operator[](const integral&) volatile noexcept;
integral operator[](const integral&) noexcept;
integral operator[](integral) volatile noexcept;
integral operator[](integral) noexcept;
void wait(integral, memory_order = memory_order::seq_cst) const volatile noexcept;
void wait(integral, memory_order = memory_order::seq_cst) const noexcept;
void notify_one() volatile noexcept;
void notify_one() noexcept;
void notify_all() volatile noexcept;
void notify_all() noexcept;

The atomic integral specializations are standard-layout structs. They each have a trivial destructor.

Descriptions are provided below only for members that differ from the primary template.

The following operations perform arithmetic computations. The key, operator, and computation correspondence is:

<table>
<thead>
<tr>
<th>Key</th>
<th>Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>+</td>
<td>addition</td>
</tr>
<tr>
<td>or</td>
<td></td>
<td>bitwise inclusive or</td>
</tr>
<tr>
<td>and</td>
<td>&amp;</td>
<td>bitwise and</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Key</th>
<th>Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>sub</td>
<td>-</td>
<td>subtraction</td>
</tr>
<tr>
<td>xor</td>
<td>^</td>
<td>bitwise exclusive or</td>
</tr>
</tbody>
</table>

T fetch_key(T operand, memory_order order = memory_order::seq_cst) volatile noexcept;
T fetch_key(T operand, memory_order order = memory_order::seq_cst) noexcept;

**Constraints:** For the volatile overload of this function, is_always_lock_free is true.

**Effects:** Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2).

**Returns:** Atomically, the value pointed to by this immediately before the effects.

**Remarks:** For signed integer types, the result is as if the object value and parameters were converted to their corresponding unsigned types, the computation performed on those types, and the result converted back to the signed type. [Note: There are no undefined results arising from the computation. — end note]

T operator op=(T operand) volatile noexcept;
T operator op=(T operand) noexcept;

**Constraints:** For the volatile overload of this function, is_always_lock_free is true.

**Effects:** Equivalent to: return fetch_key(operand) op operand;

### 31.8.3 Specializations for floating-point types

There are specializations of the atomic class template for the floating-point types float, double, and long_double. For each such type floating-point, the specialization atomic<floating-point> provides additional atomic operations appropriate to floating-point types.

```cpp
namespace std {
    template<> struct atomic<floating-point> { 
        using value_type = floating-point;
        using difference_type = value_type;

        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;

        constexpr atomic() noexcept;
        constexpr atomic(floating-point) noexcept;
        atomic(const atomic&) = delete;
        atomic& operator=(const atomic&) = delete;
        atomic& operator=(const atomic&) volatile = delete;

        void store(floating-point, memory_order = memory_order::seq_cst) volatile noexcept;
        void store(floating-point, memory_order = memory_order::seq_cst) noexcept;
        floating-point operator=(floating-point) volatile noexcept;
    }
}
```
The atomic floating-point specializations are standard-layout structs. They each have a trivial destructor.

3 Descriptions are provided below only for members that differ from the primary template.

4 The following operations perform arithmetic addition and subtraction computations. The key, operator, and computation correspondence are identified in Table 144.

5 Constraints: For the volatile overload of this function, is_always_lock_free is true.

6 Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2).

7 Returns: Atomically, the value pointed to by this immediately before the effects.
Remarks: If the result is not a representable value for its type (7.1) the result is unspecified, but the operations otherwise have no undefined behavior. Atomic arithmetic operations on floating-point should conform to the std::numeric_limits-floating-point traits associated with the floating-point type (17.3.3). The floating-point environment (26.3) for atomic arithmetic operations on floating-point may be different than the calling thread’s floating-point environment.

T operator op=(T operand) volatile noexcept;
T operator op=(T operand) noexcept;

Constraints: For the volatile overload of this function, is_always_lock_free is true.

Effects: Equivalent to: return fetch_key(operand) op operand;

Remarks: If the result is not a representable value for its type (7.1) the result is unspecified, but the operations otherwise have no undefined behavior. Atomic arithmetic operations on floating-point should conform to the std::numeric_limits-floating-point traits associated with the floating-point type (17.3.3). The floating-point environment (26.3) for atomic arithmetic operations on floating-point may be different than the calling thread’s floating-point environment.

31.8.4 Partial specialization for pointers

namespace std {

    template<class T> struct atomic<T*> {
        using value_type = T*;
        using difference_type = ptrdiff_t;

        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;
        constexpr atomic() noexcept;
        constexpr atomic(T*) noexcept;
        atomic(const atomic&) = delete;
        atomic& operator=(const atomic&) = delete;
        atomic& operator=(const atomic&) volatile = delete;
        void store(T*, memory_order = memory_order::seq_cst) volatile noexcept;
        void store(T*, memory_order = memory_order::seq_cst) noexcept;
        T* operator=(T*) volatile noexcept;
        T* operator=(T*) noexcept;
        T* load(memory_order = memory_order::seq_cst) const volatile noexcept;
        T* load(memory_order = memory_order::seq_cst) const noexcept;
        operator T*() const volatile noexcept;
        operator T*() const noexcept;
        T* exchange(T*, memory_order = memory_order::seq_cst) volatile noexcept;
        T* exchange(T*, memory_order = memory_order::seq_cst) noexcept;
        bool compare_exchange_weak(T*&, T*, memory_order, memory_order) volatile noexcep;
        bool compare_exchange_weak(T*&, T*, memory_order, memory_order) noexcep;
        bool compare_exchange_strong(T*&, T*, memory_order, memory_order) volatile noexcep;
        bool compare_exchange_strong(T*&, T*, memory_order, memory_order) noexcep;
        bool compare_exchange_weak(T*&, T*, memory_order = memory_order::seq_cst) volatile noexcep;
        bool compare_exchange_weak(T*&, T*, memory_order = memory_order::seq_cst) noexcep;
        bool compare_exchange_strong(T*&, T*, memory_order = memory_order::seq_cst) volatile noexcep;
        bool compare_exchange_strong(T*&, T*, memory_order = memory_order::seq_cst) noexcep;
        T* fetch_add(ptrdiff_t, memory_order = memory_order::seq_cst) volatile noexcep;
        T* fetch_add(ptrdiff_t, memory_order = memory_order::seq_cst) noexcep;
        T* fetch_sub(ptrdiff_t, memory_order = memory_order::seq_cst) volatile noexcep;
        T* fetch_sub(ptrdiff_t, memory_order = memory_order::seq_cst) noexcep;
    }

}
T* operator++(int) volatile noexcept;
T* operator++(int) noexcept;
T* operator--(int) volatile noexcept;
T* operator--(int) noexcept;
T* operator++() volatile noexcept;
T* operator++() noexcept;
T* operator--() volatile noexcept;
T* operator--() noexcept;
T* operator+=(ptrdiff_t) volatile noexcept;
T* operator+=(ptrdiff_t) noexcept;
T* operator-=(ptrdiff_t) volatile noexcept;
T* operator-=(ptrdiff_t) noexcept;
void wait(T*, memory_order = memory_order::seq_cst) const volatile noexcept;
void wait(T*, memory_order = memory_order::seq_cst) const noexcept;
void notify_one() volatile noexcept;
void notify_one() noexcept;
void notify_all() volatile noexcept;
void notify_all() noexcept;
);

1 There is a partial specialization of the atomic class template for pointers. Specializations of this partial specialization are standard-layout structs. They each have a trivial destructor.

2 Descriptions are provided below only for members that differ from the primary template.

3 The following operations perform pointer arithmetic. The key, operator, and computation correspondence is:

Table 145: Atomic pointer computations  

<table>
<thead>
<tr>
<th>key</th>
<th>Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>+</td>
<td>addition</td>
</tr>
<tr>
<td>sub</td>
<td>-</td>
<td>subtraction</td>
</tr>
</tbody>
</table>

T* fetch_key(ptrdiff_t operand, memory_order order = memory_order::seq_cst) volatile noexcept;
T* fetch_key(ptrdiff_t operand, memory_order order = memory_order::seq_cst) noexcept;

4 Constraints: For the volatile overload of this function, is_always_lock_free is true.

5 Mandates: T is a complete object type. [Note: Pointer arithmetic on void* or function pointers is ill-formed. — end note]

6 Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2).

7 Returns: Atomically, the value pointed to by this immediately before the effects.

8 Remarks: The result may be an undefined address, but the operations otherwise have no undefined behavior.

T* operator op=(ptrdiff_t operand) volatile noexcept;
T* operator op=(ptrdiff_t operand) noexcept;

9 Constraints: For the volatile overload of this function, is_always_lock_free is true.

10 Effects: Equivalent to: return fetch_key (operand) op operand;

31.8.5 Member operators common to integers and pointers to objects  

value_type operator++(int) volatile noexcept;
value_type operator++(int) noexcept;

1 Constraints: For the volatile overload of this function, is_always_lock_free is true.

2 Effects: Equivalent to: return fetch_add(1);

value_type operator--(int) volatile noexcept;
value_type operator--(int) noexcept;

3 Constraints: For the volatile overload of this function, is_always_lock_free is true.
4  

   Effects: Equivalent to: return fetch_sub(1);

value_type operator++() volatile noexcept;
value_type operator++() noexcept;

5  

   Constraints: For the volatile overload of this function, is_always_lock_free is true.

6  

   Effects: Equivalent to: return fetch_add(1) + 1;

value_type operator--() volatile noexcept;
value_type operator--() noexcept;

7  

   Constraints: For the volatile overload of this function, is_always_lock_free is true.

8  

   Effects: Equivalent to: return fetch_sub(1) - 1;

### 31.8.6 Partial specializations for smart pointers

The library provides partial specializations of the `atomic` template for shared-ownership smart pointers (20.11). The behavior of all operations is as specified in 31.8, unless specified otherwise. The template parameter T of these partial specializations may be an incomplete type.

All changes to an atomic smart pointer in this subclause, and all associated `use_count` increments, are guaranteed to be performed atomically. Associated `use_count` decrements are sequenced after the atomic operation, but are not required to be part of it. Any associated deletion and deallocation are sequenced after the atomic update step and are not part of the atomic operation. [Note: If the atomic operation uses locks, locks acquired by the implementation will be held when any `use_count` adjustments are performed, and will not be held when any destruction or deallocation resulting from this is performed. — end note]

[Example:

```cpp
template<typename T> class atomic_list {
    struct node {
        T t;
        shared_ptr<node> next;
    };
    atomic<shared_ptr<node>> head;

    public:
    auto find(T t) const {
        auto p = head.load();
        while (p && p->t != t)
            p = p->next;

        return shared_ptr<node>(move(p));
    }

    void push_front(T t) {
        auto p = make_shared<node>();
        p->t = t;
        p->next = head;
        while (!head.compare_exchange_weak(p->next, p)) {}
    }
};
```

— end example]

### 31.8.6.1 Partial specialization for shared_ptr

```cpp
namespace std {
    template<class T> struct atomic<shared_ptr<T>> {
        using value_type = shared_ptr<T>;

        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const noexcept;

        constexpr atomic() noexcept;
        atomic(shared_ptr<T> desired) noexcept;
        atomic(const atomic&) = delete;
    }
}
```
void operator=(const atomic&) = delete;

shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
operator shared_ptr<T>() const noexcept;
void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
void operator=(shared_ptr<T> desired) noexcept;

shared_ptr<T> exchange(shared_ptr<T> desired,
memory_order order = memory_order::seq_cst) noexcept;
bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
memory_order success, memory_order failure) noexcept;
bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
memory_order success, memory_order failure) noexcept;
bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
memory_order order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
memory_order order = memory_order::seq_cst) noexcept;

void wait(shared_ptr<T> old, memory_order order = memory_order::seq_cst) const noexcept;
void notify_one() noexcept;
void notify_all() noexcept;

private:
shared_ptr<T> p;                  // exposition only
};

constexpr atomic() noexcept;
atomic(shared_ptr<T> desired) noexcept;
Effects: Initializes p{desired}.
atomic(shared_ptr<T> desired) noexcept;
Effects: Initializes the object with the value desired. Initialization is not an atomic operation (6.9.2). [Note: It is possible to have an access to an atomic object A race with its construction, for example, by communicating the address of the just-constructed object A to another thread via memory_order::relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. — end note]

void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
Preconditions: order is neither memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.
Effects: Atomically replaces the value pointed to by this with the value of desired as if by p.swap(desired). Memory is affected according to the value of order.

void operator=(shared_ptr<T> desired) noexcept;
Effects: Equivalent to store(desired).

shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
Preconditions: order is neither memory_order::release nor memory_order::acq_rel.
Effects: Memory is affected according to the value of order.
Returns: Atomically returns p.

operator shared_ptr<T>() const noexcept;
Effects: Equivalent to: return load();

shared_ptr<T> exchange(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
Effects: Atomically replaces p with desired as if by p.swap(desired). Memory is affected according to the value of order. This is an atomic read-modify-write operation (6.9.2.1).
Returns: Atomically returns the value of p immediately before the effects.
**bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired, memory_order success, memory_order failure) noexcept;**

**Preconditions:** failure is neither memory_order::release nor memory_order::acq_rel.

**Effects:** If p is equivalent to expected, assigns desired to p and has synchronization semantics corresponding to the value of success, otherwise assigns p to expected and has synchronization semantics corresponding to the value of failure.

**Returns:** true if p was equivalent to expected, false otherwise.

**Remarks:** Two shared_ptr objects are equivalent if they store the same pointer value and either share ownership or are both empty. The weak form may fail spuriously. See 31.8.1.

If the operation returns true, expected is not accessed after the atomic update and the operation is an atomic read-modify-write operation (6.9.2) on the memory pointed to by this. Otherwise, the operation is an atomic load operation on that memory, and expected is updated with the existing value read from the atomic object in the attempted atomic update. The use_count update corresponding to the write to expected is part of the atomic operation. The write to expected itself is not required to be part of the atomic operation.

**bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;**

**Effects:** Equivalent to:

```cpp
return compare_exchange_weak(expected, desired, order, fail_order);
```

where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

**bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;**

**Effects:** Equivalent to:

```cpp
return compare_exchange_strong(expected, desired, order, fail_order);
```

where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

**void wait(shared_ptr<T> old, memory_order order = memory_order::seq_cst) const noexcept;**

**Preconditions:** order is neither memory_order::release nor memory_order::acq_rel.

**Effects:** Repeatedly performs the following steps, in order:

1. Evaluates load(order) and compares it to old.
2. If the two are not equivalent, returns.
3. Blocks until it is unblocked by an atomic notifying operation or is unblocked spuriously.

**Remarks:** Two shared_ptr objects are equivalent if they store the same pointer and either share ownership or are both empty. This function is an atomic waiting operation (31.6).

**void notify_one() noexcept;**

**Effects:** Unblocks the execution of at least one atomic waiting operation that is eligible to be unblocked (31.6) by this call, if any such atomic waiting operations exist.

**Remarks:** This function is an atomic notifying operation (31.6).

**void notify_all() noexcept;**

**Effects:** Unblocks the execution of all atomic waiting operations that are eligible to be unblocked (31.6) by this call.

**Remarks:** This function is an atomic notifying operation (31.6).
### 31.8.6.2 Partial specialization for `weak_ptr`

```cpp
namespace std {
    template<class T> struct atomic<weak_ptr<T>> {
        using value_type = weak_ptr<T>;
        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const noexcept;
        constexpr atomic() noexcept;
        atomic(weak_ptr<T> desired) noexcept;
        atomic(const atomic&) = delete;
        void operator=(const atomic&) = delete;
        weak_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
        operator weak_ptr<T>() const noexcept;
        void store(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        void operator=(weak_ptr<T> desired) noexcept;
        weak_ptr<T> exchange(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;
        bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;
        void wait(weak_ptr<T> old, memory_order order = memory_order::seq_cst) const noexcept;
        void notify_one() noexcept;
        void notify_all() noexcept;
        private:
        weak_ptr<T> p;  // exposition only
    };
    constexpr atomic() noexcept;
}
```

1. **Effects:** Initializes `p`.
2. **Effects:** Initializes the object with the value `desired`. Initialization is not an atomic operation (6.9.2). [Note: It is possible to have an access to an atomic object `A` race with its construction, for example, by communicating the address of the just-constructed object `A` to another thread via `memory_order::relaxed` operations on a suitable atomic pointer variable, and then immediately accessing `A` in the receiving thread. This results in undefined behavior. — end note]
3. **Preconditions:** `order` is neither `memory_order::consume`, `memory_order::acquire`, nor `memory_order::acq_rel`.
4. **Effects:** Atomically replaces the value pointed to by `this` with the value of `desired` as if by `p.swap(desired)`. Memory is affected according to the value of `order`.
5. **Effects:** Equivalent to `store(desired)`.
6. **Preconditions:** `order` is neither `memory_order::release` nor `memory_order::acq_rel`.
7. **Effects:** Memory is affected according to the value of `order`.
Returns: Atomically returns p.

operator weak_ptr<T>() const noexcept;

Effects: Equivalent to: return load();

weak_ptr<T> exchange(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically replaces p with desired as if by p.swap(desired). Memory is affected according to the value of order. This is an atomic read-modify-write operation (6.9.2.1).

Returns: Atomically returns the value of p immediately before the effects.

bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;
bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;

Preconditions: failure is neither memory_order::release nor memory_order::acq_rel.

Effects: If p is equivalent to expected, assigns desired to p and has synchronization semantics corresponding to the value of success, otherwise assigns p to expected and has synchronization semantics corresponding to the value of failure.

Returns: true if p was equivalent to expected, false otherwise.

Remarks: Two weak_ptr objects are equivalent if they store the same pointer value and either share ownership or are both empty. The weak form may fail spuriously. See 31.8.1.

If the operation returns true, expected is not accessed after the atomic update and the operation is an atomic read-modify-write operation (6.9.2) on the memory pointed to by this. Otherwise, the operation is an atomic load operation on that memory, and expected is updated with the existing value read from the atomic object in the attempted atomic update. The use_count update corresponding to the write to expected is part of the atomic operation. The write to expected itself is not required to be part of the atomic operation.

bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Equivalent to:

    return compare_exchange_weak(expected, desired, order, fail_order);

where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Equivalent to:

    return compare_exchange_strong(expected, desired, order, fail_order);

where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

void wait(weak_ptr<T> old, memory_order order = memory_order::seq_cst) const noexcept;

Preconditions: order is neither memory_order::release nor memory_order::acq_rel.

Effects: Repeatedly performs the following steps, in order:

- Evaluates load(order) and compares it to old.
- If the two are not equivalent, returns.
- Blocks until it is unblocked by an atomic notifying operation or is unblocked spuriously.

Remarks: Two weak_ptr objects are equivalent if they store the same pointer and either share ownership or are both empty. This function is an atomic waiting operation (31.6).
void notify_one() noexcept;

Effects: Unblocks the execution of at least one atomic waiting operation that is eligible to be unblocked (31.6) by this call, if any such atomic waiting operations exist.

Remarks: This function is an atomic notifying operation (31.6).

void notify_all() noexcept;

Effects: Unblocks the execution of all atomic waiting operations that are eligible to be unblocked (31.6) by this call.

Remarks: This function is an atomic notifying operation (31.6).

31.9 Non-member functions

A non-member function template whose name matches the pattern atomic_f or the pattern atomic_f_explicit invokes the member function f, with the value of the first parameter as the object expression and the values of the remaining parameters (if any) as the arguments of the member function call, in order. An argument for a parameter of type atomic<T>::value_type* is dereferenced when passed to the member function call. If no such member function exists, the program is ill-formed.

[Note: The non-member functions enable programmers to write code that can be compiled as either C or C++, for example in a shared header file. — end note]

31.10 Flag type and operations

namespace std {

  struct atomic_flag {
    constexpr atomic_flag() noexcept;
    atomic_flag(const atomic_flag&) = delete;
    atomic_flag& operator=(const atomic_flag&) = delete;
    atomic_flag& operator=(const atomic_flag&) volatile = delete;

    bool test(memory_order = memory_order::seq_cst) const volatile noexcept;
    bool test(memory_order = memory_order::seq_cst) const noexcept;
    bool test_and_set(memory_order = memory_order::seq_cst) volatile noexcept;
    bool test_and_set(memory_order = memory_order::seq_cst) noexcept;
    void clear(memory_order = memory_order::seq_cst) volatile noexcept;
    void clear(memory_order = memory_order::seq_cst) noexcept;
    void wait(bool, memory_order = memory_order::seq_cst) const volatile noexcept;
    void wait(bool, memory_order = memory_order::seq_cst) const noexcept;
    void notify_one() volatile noexcept;
    void notify_one() noexcept;
    void notify_all() volatile noexcept;
    void notify_all() noexcept;
  };

1 The atomic_flag type provides the classic test-and-set functionality. It has two states, set and clear.

2 Operations on an object of type atomic_flag shall be lock-free. [Note: Hence the operations should also be address-free. — end note]

3 The atomic_flag type is a standard-layout struct. It has a trivial destructor.

    constexpr atomic_flag::atomic_flag() noexcept;

4 Effects: Initializes *this to the clear state.

    bool atomic_flag_test(const volatile atomic_flag* object) noexcept;
    bool atomic_flag_test(const atomic_flag* object) noexcept;
    bool atomic_flag_test_explicit(const volatile atomic_flag* object, memory_order order) noexcept;
    bool atomic_flag_test_explicit(const atomic_flag* object, memory_order order) noexcept;
    bool atomic_flag::test(memory_order order = memory_order::seq_cst) const volatile noexcept;

§ 31.10 1516
bool atomic_flag::test(memory_order order = memory_order::seq_cst) const noexcept;

For atomic_flag_test, let order be memory_order::seq_cst.

Preconditions: order is neither memory_order::release nor memory_order::acq_rel.

Effects: Memory is affected according to the value of order.

Returns: Atomically returns the value pointed to by object or this.

bool atomic_flag::test_and_set(memory_order order = memory_order::seq_cst) volatile noexcept;

For atomic_flag_test_and_set, let order be memory_order::seq_cst.

bool atomic_flag_test_and_set(volatile atomic_flag* object) noexcept;

bool atomic_flag_test_and_set(atomic_flag* object) noexcept;

bool atomic_flag_test_and_set_explicit(volatile atomic_flag* object, memory_order order) noexcept;

bool atomic_flag_test_and_set_explicit(atomic_flag* object, memory_order order) noexcept;

bool atomic_flag::test_and_set(memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically sets the value pointed to by object or by this to true. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.9.2).

Returns: Atomically, the value of the object immediately before the effects.

void atomic_flag_clear(volatile atomic_flag* object) noexcept;

void atomic_flag_clear(atomic_flag* object) noexcept;

void atomic_flag_clear_explicit(volatile atomic_flag* object, memory_order order) noexcept;

void atomic_flag_clear_explicit(atomic_flag* object, memory_order order) noexcept;

void atomic_flag::clear(memory_order order = memory_order::seq_cst) volatile noexcept;

void atomic_flag::clear(memory_order order = memory_order::seq_cst) noexcept;

Preconditions: The order argument is neither memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically sets the value pointed to by object or by this to false. Memory is affected according to the value of order.

void atomic_flag_wait(const volatile atomic_flag* object, bool old) noexcept;

void atomic_flag_wait(const atomic_flag* object, bool old) noexcept;

void atomic_flag_wait_explicit(const volatile atomic_flag* object, bool old, memory_order order) noexcept;

void atomic_flag_wait_explicit(const atomic_flag* object, bool old, memory_order order) noexcept;

void atomic_flag::wait(bool old, memory_order order = memory_order::seq_cst) const volatile noexcept;

void atomic_flag::wait(bool old, memory_order order = memory_order::seq_cst) const noexcept;

For atomic_flag_wait, let order be memory_order::seq_cst. Let flag be object for the non-member functions and this for the member functions.

Preconditions: order is neither memory_order::release nor memory_order::acq_rel.

Effects: Repeatedly performs the following steps, in order:

(15.1) Evaluates flag->test(order) != old.

(15.2) If the result of that evaluation is true, returns.

(15.3) Blocks until it is unblocked by an atomic notifying operation or is unblocked spuriously.

Remarks: This function is an atomic waiting operation (31.6).

void atomic_flag::notify_one() volatile noexcept;

void atomic_flag::notify_one() noexcept;

Effects: Unblocks the execution of at least one atomic waiting operation that is eligible to be unblocked (31.6) by this call, if any such atomic waiting operations exist.

Remarks: This function is an atomic notifying operation (31.6).
### 31.11 Fences

This subclause introduces synchronization primitives called fences. Fences can have acquire semantics, release semantics, or both. A fence with acquire semantics is called an *acquire fence*. A fence with release semantics is called a *release fence*.

1 A release fence $A$ synchronizes with an acquire fence $B$ if there exist atomic operations $X$ and $Y$, both operating on some atomic object $M$, such that $A$ is sequenced before $X$, $X$ modifies $M$, $Y$ is sequenced before $B$, and $Y$ reads the value written by $X$ or a value written by any side effect in the hypothetical release sequence $X$ would head if it were a release operation.

2 A release fence $A$ synchronizes with an atomic operation $B$ that performs an acquire operation on an atomic object $M$ if there exists an atomic operation $X$ such that $A$ is sequenced before $X$, $X$ modifies $M$, and $B$ reads the value written by $X$ or a value written by any side effect in the hypothetical release sequence $X$ would head if it were a release operation.

3 An atomic operation $A$ that is a release operation on an atomic object $M$ synchronizes with an acquire fence $B$ if there exists some atomic operation $X$ on $M$ such that $X$ is sequenced before $B$ and reads the value written by $A$ or a value written by any side effect in the release sequence headed by $A$.

*extern "C" void atomic_thread_fence(memory_order order) noexcept;*

5 **Effects:** Depending on the value of `order`, this operation:

5.1 - has no effects, if `order == memory_order::relaxed`;
5.2 - is an acquire fence, if `order == memory_order::acquire` or `order == memory_order::consume`;
5.3 - is a release fence, if `order == memory_order::release`;
5.4 - is both an acquire fence and a release fence, if `order == memory_order::acq_rel`;
5.5 - is a sequentially consistent acquire and release fence, if `order == memory_order::seq_cst`.

*extern "C" void atomic_signal_fence(memory_order order) noexcept;*

6 **Effects:** Equivalent to `atomic_thread_fence(order)`, except that the resulting ordering constraints are established only between a thread and a signal handler executed in the same thread.

7 [*Note:* `atomic_signal_fence` can be used to specify the order in which actions performed by the thread become visible to the signal handler. Compiler optimizations and reorderings of loads and stores are inhibited in the same way as with `atomic_thread_fence`, but the hardware fence instructions that `atomic_thread_fence` would have inserted are not emitted. — *end note*]
32 Thread support library

### 32.1 General

The following subclauses describe components to create and manage threads (6.9.2), perform mutual exclusion, and communicate conditions and values between threads, as summarized in Table 146.

</tbody>
</table>

### 32.2 Requirements

#### 32.2.1 Template parameter names

Throughout this Clause, the names of template parameters are used to express type requirements. If a template parameter is named `Predicate`, `operator()` applied to the template argument shall return a value that is convertible to `bool`. If a template parameter is named `Clock`, the corresponding template argument shall be a type `C` for which `is_clock_v<C>` is true; otherwise the program is ill-formed.

#### 32.2.2 Exceptions

Some functions described in this Clause are specified to throw exceptions of type `system_error` (19.5.7). Such exceptions are thrown if any of the function’s error conditions is detected or a call to an operating system or other underlying API results in an error that prevents the library function from meeting its specifications. Failure to allocate storage is reported as described in 16.5.5.13.

**Example:** Consider a function in this Clause that is specified to throw exceptions of type `system_error` and specifies error conditions that include `operation_not_permitted` for a thread that does not have the privilege to perform the operation. Assume that, during the execution of this function, an `errno` of `EPERM` is reported by a POSIX API call used by the implementation. Since POSIX specifies an `errno` of `EPERM` when “the caller does not have the privilege to perform the operation”, the implementation maps `EPERM` to an `error_condition` of `operation_not_permitted` (19.5) and an exception of type `system_error` is thrown.

#### 32.2.3 Native handles

Several classes described in this Clause have members `native_handle_type` and `native_handle`. The presence of these members and their semantics is implementation-defined. [Note: These members allow implementations to provide access to implementation details. Their names are specified to facilitate portable compile-time detection. Actual use of these members is inherently non-portable. — end note]

#### 32.2.4 Timing specifications

Several functions described in this Clause take an argument to specify a timeout. These timeouts are specified as either a `duration` or a `time_point` type as specified in Clause 27.

Implementations necessarily have some delay in returning from a timeout. Any overhead in interrupt response, function return, and scheduling induces a “quality of implementation” delay, expressed as duration $D_i$. Ideally, this delay would be zero. Further, any contention for processor and memory resources induces a “quality of management”
delay, expressed as duration \( D_n \). The delay durations may vary from timeout to timeout, but in all cases shorter is better.

3 The functions whose names end in \_for take an argument that specifies a duration. These functions produce relative timeouts. Implementations should use a steady clock to measure time for these functions.\(^{326}\) Given a duration argument \( D_t \), the real-time duration of the timeout is \( D_t + D_i + D_m \).

4 The functions whose names end in \_until take an argument that specifies a time point. These functions produce absolute timeouts. Implementations should use the clock specified in the time point to measure time for these functions. Given a clock time point argument \( C_t \), the clock time point of the return from timeout should be \( C_t + D_i + D_m \) when the clock is not adjusted during the timeout. If the clock is adjusted to the time \( C_n \) during the timeout, the behavior should be as follows:

\[
\begin{align*}
\text{(4.1)} & \quad \text{if } C_n > C_t, \text{ the waiting function should wake as soon as possible, i.e., } C_n + D_i + D_m, \text{ since the timeout is already satisfied. This specification may result in the total duration of the wait decreasing when measured against a steady clock.} \\
\text{(4.2)} & \quad \text{if } C_n \leq C_t, \text{ the waiting function should not time out until } \text{Clock::now()} \text{ returns a time } C_n \geq C_t, \text{ i.e., waking at } C_t + D_i + D_m. \text{ [Note: When the clock is adjusted backwards, this specification can result in the total duration of the wait increasing when measured against a steady clock. When the clock is adjusted forwards, this specification can result in the total duration of the wait decreasing when measured against a steady clock. — end note]} \\
\end{align*}
\]

An implementation returns from such a timeout at any point from the time specified above to the time it would return from a steady-clock relative timeout on the difference between \( C_t \) and the time point of the call to the \_until function. \([\text{Note: Implementations should decrease the duration of the wait when the clock is adjusted forwards. — end note}]\)

5 \([\text{Note: If the clock is not synchronized with a steady clock, e.g., a CPU time clock, these timeouts might not provide useful functionality. — end note}]\)

6 The resolution of timing provided by an implementation depends on both operating system and hardware. The finest resolution provided by an implementation is called the native resolution.

7 Implementation-provided clocks that are used for these functions meet the Cpp17TrivialClock requirements (27.3).

8 A function that takes an argument which specifies a timeout will throw if, during its execution, a clock, time point, or time duration throws an exception. Such exceptions are referred to as timeout-related exceptions. \([\text{Note: Instantiations of clock, time point and duration types supplied by the implementation as specified in 27.7 do not throw exceptions. — end note}]\)

### 32.2.5 Requirements for Cpp17Lockable types

#### 32.2.5.1 In general

1 An execution agent is an entity such as a thread that may perform work in parallel with other execution agents. \([\text{Note: Implementations or users can introduce other kinds of agents such as processes or thread-pool tasks. — end note}]\)

The calling agent is determined by context, e.g., the calling thread that contains the call, and so on.

2 \([\text{Note: Some lockable objects are “agent oblivious” in that they work for any execution agent model because they do not determine or store the agent’s ID (e.g., an ordinary spin lock). — end note}]\)

3 The standard library templates unique_lock (32.5.4.3), shared_lock (32.5.4.4), scoped_lock (32.5.4.2), lock_guard (32.5.4.1), lock, try_lock (32.5.5), and condition_variable_any (32.6.4) all operate on user-supplied lockable objects. The Cpp17BasicLockable requirements, the Cpp17Lockable requirements, and the Cpp17TimedLockable requirements list the requirements imposed by these library types in order to acquire or release ownership of a lock by a given execution agent. \([\text{Note: The nature of any lock ownership and any synchronization it entails are not part of these requirements. — end note}]\)

#### 32.2.5.2 Cpp17BasicLockable requirements

1 A type L meets the Cpp17BasicLockable requirements if the following expressions are well-formed and have the specified semantics (\( \& \) denotes a value of type L).

\[\begin{align*}
\text{§ 32.2.5.2} & \quad 1520
\end{align*}\]

---

\(^{326}\) All implementations for which standard time units are meaningful must necessarily have a steady clock within their hardware implementation.
m.lock()  
   Effects: Blocks until a lock can be acquired for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

m.unlock()  
   Preconditions: The current execution agent holds a lock on m.  
   Effects: Releases a lock on m held by the current execution agent.  
   Throws: Nothing.

32.2.5 Cpp17Lockable requirements  
A type L meets the Cpp17Lockable requirements if it meets the Cpp17BasicLockable requirements and the following expressions are well-formed and have the specified semantics (m denotes a value of type L).

m.try_lock()  
   Effects: Attempts to acquire a lock for the current execution agent without blocking. If an exception is thrown then a lock shall not have been acquired for the current execution agent.  
   Return type: bool.  
   Returns: true if the lock was acquired, false otherwise.

m.try_lock_for(rel_time)  
   Effects: Attempts to acquire a lock for the current execution agent within the relative timeout (32.2.4) specified by rel_time. The function will not return within the timeout specified by rel_time unless it has obtained a lock on m for the current execution agent. If an exception is thrown then a lock has not been acquired for the current execution agent.  
   Return type: bool.  
   Returns: true if the lock was acquired, false otherwise.

m.try_lock_until(abs_time)  
   Effects: Attempts to acquire a lock for the current execution agent before the absolute timeout (32.2.4) specified by abs_time. The function will not return before the timeout specified by abs_time unless it has obtained a lock on m for the current execution agent. If an exception is thrown then a lock has not been acquired for the current execution agent.  
   Return type: bool.  
   Returns: true if the lock was acquired, false otherwise.

32.3 Stop tokens  
32.3.1 Introduction  
Subclause 32.3 describes components that can be used to asynchronously request that an operation stops execution in a timely manner, typically because the result is no longer required. Such a request is called a stop request.

stop_source, stop_token, and stop_callback implement semantics of shared ownership of a stop state. Any stop_source, stop_token, or stop_callback that shares ownership of the same stop state is an associated stop_source, stop_token, or stop_callback, respectively. The last remaining owner of the stop state automatically releases the resources associated with the stop state.

A stop_token can be passed to an operation which can either
   — actively poll the token to check if there has been a stop request, or
   — register a callback using the stop_callback class template which will be called in the event that a stop request is made.
A stop request made via a stop_source will be visible to all associated stop_token and stop_source objects. Once a stop request has been made it cannot be withdrawn (a subsequent stop request has no effect).

4 Callbacks registered via a stop_callback object are called when a stop request is first made by any associated stop_source object.

5 Calls to the functions request_stop, stop_requested, and stop_possible do not introduce data races. A call to request_stop that returns true synchronizes with a call to stop_requested on an associated stop_token or stop_source object that returns true. Registration of a callback synchronizes with the invocation of that callback.

32.3.2 Header <stop_token> synopsis

namespace std {
    // 32.3.3, class stop_token
    class stop_token;

    // 32.3.4, class stop_source
    class stop_source;

    // no-shared-stop-state indicator
    struct nostopstate_t {
        explicit nostopstate_t() = default;
    };
    inline constexpr nostopstate_t nostopstate{};

    // 32.3.5, class stop_callback
    template<class Callback>
    class stop_callback;
}

32.3.3 Class stop_token

1 The class stop_token provides an interface for querying whether a stop request has been made (stop_requested) or can ever be made (stop_possible) using an associated stop_source object (32.3.4). A stop_token can also be passed to a stop_callback (32.3.5) constructor to register a callback to be called when a stop request has been made from an associated stop_source.

namespace std {
    class stop_token {
        public:
            // 32.3.3.1, constructors, copy, and assignment
            stop_token() noexcept;
            stop_token(const stop_token&) noexcept;
            stop_token(stop_token&&) noexcept;
            stop_token& operator=(const stop_token&) noexcept;
            stop_token& operator=(stop_token&&) noexcept;
            ~stop_token();
            void swap(stop_token&) noexcept;

            // 32.3.3.2, stop handling
            [[nodiscard]] bool stop_requested() const noexcept;
            [[nodiscard]] bool stop_possible() const noexcept;

            [[nodiscard]] friend bool operator==(const stop_token& lhs, const stop_token& rhs) noexcept;
            friend void swap(stop_token& lhs, stop_token& rhs) noexcept;
    };
}

32.3.3.1 Constructors, copy, and assignment

1 Postconditions: stop_possible() is false and stop_requested() is false. [Note: Because the created stop_token object can never receive a stop request, no resources are allocated for a stop state. — end note]
stop_token(const stop_token& rhs) noexcept;

Postconditions: *this == rhs is true. [Note: *this and rhs share the ownership of the same stop state, if any. — end note]

stop_token(stop_token&& rhs) noexcept;

Postconditions: *this contains the value of rhs prior to the start of construction and rhs.stop_possible() is false.

~stop_token();

Effects: Releases ownership of the stop state, if any.

stop_token& operator=(const stop_token& rhs) noexcept;

Effects: Equivalent to: stop_token(rhs).swap(*this).

Returns: *this.

stop_token& operator=(stop_token&& rhs) noexcept;

Effects: Equivalent to: stop_token(std::move(rhs)).swap(*this).

Returns: *this.

void swap(stop_token& rhs) noexcept;

Effects: Exchanges the values of *this and rhs.

32.3.3.2 Members

[[nodiscard]] bool stop_requested() const noexcept;

Returns: true if *this has ownership of a stop state that has received a stop request; otherwise, false.

[[nodiscard]] bool stop_possible() const noexcept;

Returns: false if:

— *this does not have ownership of a stop state, or

— a stop request was not made and there are no associated stop_source objects; otherwise, true.

32.3.3.3 Non-member functions

[[nodiscard]] bool operator==(const stop_token& lhs, const stop_token& rhs) noexcept;

Returns: true if lhs and rhs have ownership of the same stop state or if both lhs and rhs do not have ownership of a stop state; otherwise false.

friend void swap(stop_token& x, stop_token& y) noexcept;

Effects: Equivalent to: x.swap(y).

32.3.4 Class stop_source

The class stop_source implements the semantics of making a stop request. A stop request made on a stop_source object is visible to all associated stop_source and stop_token (32.3.3) objects. Once a stop request has been made it cannot be withdrawn (a subsequent stop request has no effect).

namespace std {

// no-shared-stop-state indicator
struct nostopstate_t {
    explicit nostopstate_t() = default;
};

inline constexpr nostopstate_t nostopstate{};

class stop_source {

public:

// 32.3.4.1, constructors, copy, and assignment
stop_source();

explicit stop_source(nostopstate_t) noexcept;

};
stop_source(const stop_source&) noexcept;
stop_source(stop_source&&) noexcept;
stop_source& operator=(const stop_source&) noexcept;
stop_source& operator=(stop_source&&) noexcept;
~stop_source();
void swap(stop_source&) noexcept;

// 32.3.4.2 stop handling
[[nodiscard]] stop_token get_token() const noexcept;
[[nodiscard]] bool stop_possible() const noexcept;
[[nodiscard]] bool stop_requested() const noexcept;
bool request_stop() noexcept;

[[nodiscard]] friend bool
operator==(const stop_source& lhs, const stop_source& rhs) noexcept;
friend void swap(stop_source& lhs, stop_source& rhs) noexcept;
};

32.3.4.1 Constructors, copy, and assignment

stop_source();

Effects: Initialises *this to have ownership of a new stop state.
Postconditions: stop_possible() is true and stop_requested() is false.
Throws: bad_alloc if memory could not be allocated for the stop state.

explicit stop_source(nostopstate_t) noexcept;

Postconditions: stop_possible() is false and stop_requested() is false. [Note: No resources are allocated for the state. —end note]

stop_source(const stop_source& rhs) noexcept;

Postconditions: *this == rhs is true. [Note: *this and rhs share the ownership of the same stop state, if any. —end note]

stop_source(stop_source&& rhs) noexcept;

Postconditions: *this contains the value of rhs prior to the start of construction and rhs.stop_possible() is false.

~stop_source();

Effects: Releases ownership of the stop state, if any.

stop_source& operator=(const stop_source& rhs) noexcept;

Effects: Equivalent to: stop_source(rhs).swap(*this).
Returns: *this.

stop_source& operator=(stop_source&& rhs) noexcept;

Effects: Equivalent to: stop_source(std::move(rhs)).swap(*this).
Returns: *this.

void swap(stop_source& rhs) noexcept;

Effects: Exchanges the values of *this and rhs.

32.3.4.2 Members

[[nodiscard]] stop_token get_token() const noexcept;

Returns: stop_token() if stop_possible() is false; otherwise a new associated stop_token object.

[[nodiscard]] bool stop_possible() const noexcept;

Returns: true if *this has ownership of a stop state; otherwise, false.
32.3.4.3 Non-member functions

[[nodiscard]] friend bool operator==(const stop_source& lhs, const stop_source& rhs) noexcept;

Returns: true if lhs and rhs have ownership of the same stop state or if both lhs and rhs do not have ownership of a stop state; otherwise false.

friend void swap(stop_source& x, stop_source& y) noexcept;

Effects: Equivalent to: x.swap(y).

32.3.5 Class template stop_callback

namespace std {
    template<class Callback>
    class stop_callback {
    public:
        using callback_type = Callback;

        // 32.3.5.1, constructors and destructor
        template<class C>
        explicit stop_callback(const stop_token& st, C&& cb)
            noexcept(is_nothrow_constructible_v<Callback, C>);
        template<class C>
        explicit stop_callback(stop_token&& st, C&& cb)
            noexcept(is_nothrow_constructible_v<Callback, C>);
    ~stop_callback();

    stop_callback(const stop_callback&) = delete;
    stop_callback(stop_callback&&) = delete;
    stop_callback& operator=(const stop_callback&) = delete;
    stop_callback& operator=(stop_callback&&) = delete;

    private:
        Callback callback; // exposition only
    };

    template<class Callback>
    stop_callback(stop_token, Callback) -> stop_callback<Callback>;
}

Mandates: stop_callback is instantiated with an argument for the template parameter Callback that satisfies both invocable and destructible.

Preconditions: stop_callback is instantiated with an argument for the template parameter Callback that models both invocable and destructible.
32.3.5.1 Constructors and destructor

```cpp
template<class C>
explicit stop_callback(const stop_token& st, C&& cb)
    noexcept(is_nothrow_constructible_v<Callback, C>);

template<class C>
explicit stop_callback(stop_token&& st, C&& cb)
    noexcept(is_nothrow_constructible_v<Callback, C>);
```

**Constraints:** Callback and C satisfy `constructible_from<Callback, C>`.

**Preconditions:** Callback and C model `constructible_from<Callback, C>`.

**Effects:** Initializes callback with `std::forward<C>(cb)`. If `st.stop_requested()` is true, then `std::forward<Callback>(callback)()` is evaluated in the current thread before the constructor returns. Otherwise, if st has ownership of a stop state, acquires shared ownership of that stop state and registers the callback with that stop state such that `std::forward<Callback>(callback)()` is evaluated by the first call to `request_stop()` on an associated `stop_source`.

**Throws:** Any exception thrown by the initialization of callback.

**Remarks:** If evaluating `std::forward<Callback>(callback)()` exits via an exception, then `terminate` is called (14.6.1).

```cpp
~stop_callback();
```

**Effects:** Unregisters the callback from the owned stop state, if any. The destructor does not block waiting for the execution of another callback registered by an associated `stop_callback`. If callback is concurrently executing on another thread, then the return from the invocation of `callback` strongly happens before (6.9.2.1) `callback` is destroyed. If `callback` is executing on the current thread, then the destructor does not block (3.6) waiting for the return from the invocation of `callback`. Releases ownership of the stop state, if any.

32.4 Threads

32.4 describes components that can be used to create and manage threads. [Note: These threads are intended to map one-to-one with operating system threads. — end note]

32.4.1 Header `<thread>` synopsis

```cpp
#include <compare> // see 17.11.1

namespace std {
    class thread;
    void swap(thread& x, thread& y) noexcept;
    // 32.4.3 class jthread
class jthread;

    namespace this_thread {
        thread::id get_id() noexcept;
        void yield() noexcept;
        template<class Clock, class Duration>
            void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
        template<class Rep, class Period>
            void sleep_for(const chrono::duration<Rep, Period>& rel_time);
    }
}
```

32.4.2 Class thread

The class `thread` provides a mechanism to create a new thread of execution, to join with a thread (i.e., wait for a thread to complete), and to perform other operations that manage and query the state of a thread. A `thread` object uniquely represents a particular thread of execution. That representation may be transferred to other `thread` objects in such a way that no two `thread` objects simultaneously represent the same thread of execution. A thread of execution is detached when no `thread` object represents that thread. Objects of class `thread` can be in a state
that does not represent a thread of execution.  

--- end note

namespace std {
    class thread {
    public:
        // types
        class id;
        using native_handle_type = implementation-defined;  // see 32.2.3

        // construct/copy/destroy
        thread() noexcept;
        template<class F, class... Args> explicit thread(F&& f, Args&&... args);
        ~thread();
        thread(const thread&) = delete;
        thread(thread&&) noexcept;
        thread& operator=(const thread&) = delete;
        thread& operator=(thread&&) noexcept;

        // members
        void swap(thread&) noexcept;
        bool joinable() const noexcept;
        void join();
        void detach();
        id get_id() const noexcept;
        native_handle_type native_handle();  // see 32.2.3

        // static members
        static unsigned int hardware_concurrency() noexcept;
    };
}

32.4.2.1 Class thread::id

namespace std {
    class thread::id {
    public:
        id() noexcept;
    };

    bool operator==(thread::id x, thread::id y) noexcept;
    strong_ordering operator<=>(thread::id x, thread::id y) noexcept;

    template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_istream<charT, traits>& in, thread::id id);

    // hash support
    template<class T> struct hash;
    template<> struct hash<thread::id>;
}

1 An object of type thread::id provides a unique identifier for each thread of execution and a single distinct value for all thread objects that do not represent a thread of execution (32.4.2). Each thread of execution has an associated thread::id object that is not equal to the thread::id object of any other thread of execution and that is not equal to the thread::id object of any thread object that does not represent threads of execution.

2 thread::id is a trivially copyable class (11.2). The library may reuse the value of a thread::id of a terminated thread that can no longer be joined.

3 [Note: Relational operators allow thread::id objects to be used as keys in associative containers. — end note]

    id() noexcept;

4 Postconditions: The constructed object does not represent a thread of execution.
bool operator==(thread::id x, thread::id y) noexcept;

Returns: true only if x and y represent the same thread of execution or neither x nor y represents a thread of execution.

strong_ordering operator<=>(thread::id x, thread::id y) noexcept;

Let P(x, y) be an unspecified total ordering over thread::id as described in 25.8.

Returns: strong_ordering::less if P(x, y) is true. Otherwise, strong_ordering::greater if P(y, x) is true. Otherwise, strong_ordering::equal.

template<class charT, class traits>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& out, thread::id id);

Effects: Inserts an unspecified text representation of id into out. For two objects of type thread::id x and y, if x == y the thread::id objects have the same text representation and if x != y the thread::id objects have distinct text representations.

Returns: out.

template<> struct hash<thread::id>;

The specialization is enabled (20.14.18).

32.4.2.2 Constructors

thread() noexcept;

Effects: The object does not represent a thread of execution.

Postconditions: get_id() == id().

template<class F, class... Args> explicit thread(F&& f, Args&&... args);

Constraints: remove_cvref_t<F> is not the same type as thread.

Mandates: The following are all true:

(4.1) is_constructible_v<decay_t<F>, F>,
(4.2) (is_constructible_v<decay_t<Args>, Args> && ...),
(4.3) is_move_constructible_v<decay_t<F>>,
(4.4) (is_move_constructible_v<decay_t<Args>> && ...), and
(4.5) is_invocable_v<decay_t<F>, decay_t<Args>...>.

Preconditions: decay_t<F> and each type in decay_t<Args> meet the Cpp17MoveConstructible requirements.

Effects: The new thread of execution executes

invoke(decay-copy(std::forward<F>(f)), decay-copy(std::forward<Args>(args))...)

with the calls to decay-copy being evaluated in the constructing thread. Any return value from this invocation is ignored. [Note: This implies that any exceptions not thrown from the invocation of the copy of f will be thrown in the constructing thread, not the new thread. — end note] If the invocation of invoke terminates with an uncaught exception, terminate is called.

Synchronization: The completion of the invocation of the constructor synchronizes with the beginning of the invocation of the copy of f.

Postconditions: get_id() != id(). *this represents the newly started thread.

Throws: system_error if unable to start the new thread.

Error conditions:

(10.1) resource_unavailable_try_again — the system lacked the necessary resources to create another thread, or the system-imposed limit on the number of threads in a process would be exceeded.

thread(thread&& x) noexcept;

Postconditions: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the start of construction.
32.4.2.3 Destructor
~thread();

Effects: If joinable(), calls terminate(). Otherwise, has no effects. [Note: Either implicitly detaching or joining a joinable() thread in its destructor could result in difficult to debug correctness (for detach) or performance (for join) bugs encountered only when an exception is thrown. Thus the programmer must ensure that the destructor is never executed while the thread is still joinable. — end note]

32.4.2.4 Assignment

thread& operator=(thread&& x) noexcept;

Effects: If joinable(), calls terminate(). Otherwise, assigns the state of x to *this and sets x to a default constructed state.

Postconditions: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the assignment.

Returns: *this.

32.4.2.5 Members

void swap(thread& x) noexcept;

Effects: Swaps the state of *this and x.

bool joinable() const noexcept;

Returns: get_id() != id().

void join();

Effects: Blocks until the thread represented by *this has completed.

Synchronization: The completion of the thread represented by *this synchronizes with (6.9.2) the corresponding successful join() return. [Note: Operations on *this are not synchronized. — end note]

Postconditions: The thread represented by *this has completed. get_id() == id().

Throws: system_error when an exception is required (32.2.2).

Error conditions:
- resource_deadlock_would_occur — if deadlock is detected or get_id() == this_thread::get_id().
- no_such_process — if the thread is not valid.
- invalid_argument — if the thread is not joinable.

void detach();

Effects: The thread represented by *this continues execution without the calling thread blocking. When detach() returns, *this no longer represents the possibly continuing thread of execution. When the thread previously represented by *this ends execution, the implementation releases any owned resources.

Postconditions: get_id() == id().

Throws: system_error when an exception is required (32.2.2).

Error conditions:
- no_such_process — if the thread is not valid.
- invalid_argument — if the thread is not joinable.

id get_id() const noexcept;

Returns: A default constructed id object if *this does not represent a thread, otherwise this_thread::get_id() for the thread of execution represented by *this.

32.4.2.6 Static members

unsigned hardware_concurrency() noexcept;

Returns: The number of hardware thread contexts. [Note: This value should only be considered to be a hint. — end note] If this value is not computable or well-defined, an implementation should return 0.
32.4.2.7 Specialized algorithms

32.4.3 Class jthread

The class jthread provides a mechanism to create a new thread of execution. The functionality is the same as for class thread (32.4.2) with the additional abilities to provide a stop_token (32.3) to the new thread of execution, make stop requests, and automatically join.

namespace std {
    class jthread {
        public:
            // types
            using id = thread::id;
            using native_handle_type = thread::native_handle_type;

            // 32.4.3.1, constructors, move, and assignment
            jthread() noexcept;
            template<class F, class... Args> explicit jthread(F&& f, Args&&... args);
            ~jthread();
            jthread(const jthread&) = delete;
            jthread(jthread&&) noexcept;
            jthread& operator=(const jthread&) = delete;
            jthread& operator=(jthread&&) noexcept;

            // 32.4.3.2, members
            void swap(jthread&) noexcept;
            [[nodiscard]] bool joinable() const noexcept;
            void join();
            void detach();
            [[nodiscard]] id get_id() const noexcept;
            [[nodiscard]] native_handle_type native_handle(); // see 32.2.3

            // 32.4.3.3, stop token handling
            [[nodiscard]] stop_source get_stop_source() noexcept;
            [[nodiscard]] stop_token get_stop_token() const noexcept;
            bool request_stop() noexcept;

            // 32.4.3.4, specialized algorithms
            friend void swap(jthread& lhs, jthread& rhs) noexcept;

            // 32.4.3.5, static members
            [[nodiscard]] static unsigned int hardware_concurrency() noexcept;

        private:
            stop_source ssource; // exposition only
        }
    }
}

32.4.3.1 Constructors, move, and assignment

jthread() noexcept;

Effects: Constructs a jthread object that does not represent a thread of execution.

Postconditions: get_id() == id() is true and ssource.stop_possible() is false.

template<class F, class... Args> explicit jthread(F&& f, Args&&... args);

Constraints: remove_cvref_t<F> is not the same type as jthread.

Mandates: The following are all true:

- is_constructible_v<decay_t<F>, F>,
- (is_constructible_v<decay_t<Args>, Args> && ...),
— is_move_constructible_v<decay_t<F>>,
— (is_move_constructible_v<decay_t<Args>> && ...), and
— is_invocable_v<decay_t<F>, decay_t<Args>...> ||
  is_invocable_v<decay_t<F>, stop_token, decay_t<Args>...>.

5 Preconditions: decay_t<F> and each type in decay_t<Args> meet the Cpp17MoveConstructible requirements.
6 Effects: Initializes ssoure. The new thread of execution executes
  
  ```
  invoke(decay-copy(std::forward<F>(f)), get_stop_token(),
  decay-copy(std::forward<Args>(args))...)
  ```

  if that expression is well-formed, otherwise
  ```
  invoke(decay-copy(std::forward<F>(f)), decay-copy(std::forward<Args>(args))...)
  ```

  with the calls to decay-copy being evaluated in the constructing thread. Any return value from this invocation is ignored. [Note: This implies that any exceptions not thrown from the invocation of the copy of f will be thrown in the constructing thread, not the new thread. — end note] If the invoke expression exits via an exception, terminate is called.
7 Synchronization: The completion of the invocation of the constructor synchronizes with the beginning of the invocation of the copy of f.
8 Postconditions: get_id() != id() is true and ssoure.stop_possible() is true and *this represents the newly started thread. [Note: The calling thread can make a stop request only once, because it cannot replace this stop token. — end note] If the invoke expression exits via an exception, terminate is called.
9 Throws: system_error if unable to start the new thread.
10 Error conditions:

10.1 — resource_unavailable_try_again — the system lacked the necessary resources to create another thread, or the system-imposed limit on the number of threads in a process would be exceeded.

jthread(jthread&& x) noexcept;

11 Postconditions: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the start of construction. ssoure has the value of x.ssoure prior to the start of construction and x.ssoure.stop_possible() is false.

~jthread();
12 Effects: If joinable() is true, calls request_stop() and then join(). [Note: Operations on *this are not synchronized. — end note]

jthread& operator=(jthread&& x) noexcept;
13 Effects: If joinable() is true, calls request_stop() and then join(). Assigns the state of x to *this and sets x to a default constructed state.
14 Postconditions: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the assignment. ssoure has the value of x.ssoure prior to the assignment and x.ssoure.stop_possible() is false.
15 Returns: *this.

32.4.3.2 Members

void swap(jthread& x) noexcept;
1 Effects: Exchanges the values of *this and x.

[[nodiscard]] bool joinable() const noexcept;
2 Returns: get_id() != id().

void join();
3 Effects: Blocks until the thread represented by *this has completed.

Synchronization: The completion of the thread represented by *this synchronizes with (6.9.2) the corresponding successful join() return. [Note: Operations on *this are not synchronized. — end note]

Postconditions: The thread represented by *this has completed. get_id() == id().
**§ 32.4.4** 1532

**32.4.3.3 Stop token handling**

```cpp
[[nodiscard]] stop_source get_stop_source() noexcept;
```

*Effects:* Equivalent to: `return ssource;`

```cpp
[[nodiscard]] stop_token get_stop_token() const noexcept;
```

*Effects:* Equivalent to: `return ssource.get_token();`

```cpp
bool request_stop() noexcept;
```

*Effects:* Equivalent to: `return ssource.request_stop();`

**32.4.3.4 Specialized algorithms**

```cpp
friend void swap(jthread& x, jthread& y) noexcept;
```

*Effects:* Equivalent to: `x.swap(y).`

**32.4.3.5 Static members**

```cpp
[[nodiscard]] static unsigned int hardware_concurrency() noexcept;
```

*Returns:* `thread::hardware_concurrency().`

**32.4.4 Namespace this_thread**

```cpp
namespace std::this_thread {
    thread::id get_id() noexcept;

    void yield() noexcept;

    template<class Clock, class Duration>
    void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);

    template<class Rep, class Period>
    void sleep_for(const chrono::duration<Rep, Period>& rel_time);
}
```

*Returns:* An object of type `thread::id` that uniquely identifies the current thread of execution. No other thread of execution has this id and this thread of execution always has this id. The object returned does not compare equal to a default constructed `thread::id`. 

§ 32.4.4 1532
void this_thread::yield() noexcept;

Effects: Offers the implementation the opportunity to reschedule.
Synchronization: None.

template<class Clock, class Duration>
void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);

Effects: Blocks the calling thread for the absolute timeout (32.2.4) specified by abs_time.
Synchronization: None.
Throws: Timeout-related exceptions (32.2.4).

template<class Rep, class Period>
void sleep_for(const chrono::duration<Rep, Period>& rel_time);

Effects: Blocks the calling thread for the relative timeout (32.2.4) specified by rel_time.
Synchronization: None.
Throws: Timeout-related exceptions (32.2.4).

32.5 Mutual exclusion [thread.mutex]

This subclause provides mechanisms for mutual exclusion: mutexes, locks, and call once. These mechanisms ease the production of race-free programs (6.9.2).

32.5.1 Header <mutex> synopsis [mutex.syn]

namespace std {
    class mutex;
    class recursive_mutex;
    class timed_mutex;
    class recursive_timed_mutex;

    struct defer_lock_t { explicit defer_lock_t() = default; };
    struct try_to_lock_t { explicit try_to_lock_t() = default; };
    struct adopt_lock_t { explicit adopt_lock_t() = default; };

    inline constexpr defer_lock_t defer_lock { };
    inline constexpr try_to_lock_t try_to_lock { };
    inline constexpr adopt_lock_t adopt_lock { };

    template<class Mutex> class lock_guard;
    template<class... MutexTypes> class scoped_lock;

32.5.2 Header <shared_mutex> synopsis [shared.mutex.syn]

namespace std {
    class shared_mutex;
    class shared_timed_mutex;
    template<class Mutex> class shared_lock;
    template<class Mutex>
    void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
}

§ 32.5.2
32.5.3 Mutex requirements

32.5.3.1 In general

A mutex object facilitates protection against data races and allows safe synchronization of data between execution agents (32.2.5). An execution agent owns a mutex from the time it successfully calls one of the lock functions until it calls unlock. Mutexes can be either recursive or non-recursive, and can grant simultaneous ownership to one or many execution agents. Both recursive and non-recursive mutexes are supplied.

32.5.3.2 Mutex types

The mutex types are the standard library types mutex, recursive_mutex, timed_mutex, recursive_timed_mutex, shared_mutex, and shared_timed_mutex. They meet the requirements set out in this subclause. In this description, m denotes an object of a mutex type.

The mutex types meet the Cpp17Lockable requirements (32.2.5.3).

The mutex types meet Cpp17DefaultConstructible and Cpp17Destructible. If initialization of an object of a mutex type fails, an exception of type system_error is thrown. The mutex types are neither copyable nor movable.

The error conditions for error codes, if any, reported by member functions of the mutex types are as follows:

- resource_unavailable_try_again — if any native handle type manipulated is not available.
- operation_not_permitted — if the thread does not have the privilege to perform the operation.
- invalid_argument — if any native handle type manipulated as part of mutex construction is incorrect.

The implementation provides lock and unlock operations, as described below. For purposes of determining the existence of a data race, these behave as atomic operations (6.9.2). The lock and unlock operations on a single mutex appears to occur in a single total order. [Note: This can be viewed as the modification order (6.9.2) of the mutex. — end note] [Note: Construction and destruction of an object of a mutex type need not be thread-safe; other synchronization should be used to ensure that mutex objects are initialized and visible to other threads. — end note]

The expression m.lock() is well-formed and has the following semantics:

**Preconditions:** If m is of type mutex, timed_mutex, shared_mutex, or shared_timed_mutex, the calling thread does not own the mutex.

**Effects:** Blocks the calling thread until ownership of the mutex can be obtained for the calling thread.

**Postconditions:** The calling thread owns the mutex.

**Return type:** void.

**Synchronization:** Prior unlock() operations on the same object synchronize with (6.9.2) this operation.

**Throws:** system_error when an exception is required (32.2.2).

**Error conditions:**

- operation_not_permitted — if the thread does not have the privilege to perform the operation.
- resource_deadlock_would_occur — if the implementation detects that a deadlock would occur.

The expression m.try_lock() is well-formed and has the following semantics:

**Preconditions:** If m is of type mutex, timed_mutex, shared_mutex, or shared_timed_mutex, the calling thread does not own the mutex.

**Effects:** Attempts to obtain ownership of the mutex for the calling thread without blocking. If ownership is not obtained, there is no effect and try_lock() immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread. [Note: This spurious failure is normally uncommon, but allows interesting implementations based on a simple compare and exchange (Clause 31). — end note] An implementation should ensure that try_lock() does not consistently return false in the absence of contending mutex acquisitions.

**Return type:** bool.

**Returns:** true if ownership of the mutex was obtained for the calling thread, otherwise false.

**Synchronization:** If try_lock() returns true, prior unlock() operations on the same object synchronize with (6.9.2) this operation. [Note: Since lock() does not synchronize with a failed subsequent try_lock(), the visibility rules are weak enough that little would be known about the state after a failure, even in the absence of spurious failures. — end note]

**Throws:** Nothing.
The expression `m.unlock()` is well-formed and has the following semantics:

**Preconditions:** The calling thread owns the mutex.

**Effects:** Releases the calling thread’s ownership of the mutex.

**Return type:** `void`.

**Synchronization:** This operation synchronizes with (6.9.2) subsequent lock operations that obtain ownership on the same object.

**Throws:** Nothing.

### 32.5.3.2.1 Class `mutex`

```cpp
class mutex {
public:
    constexpr mutex() noexcept;
    ~mutex();
    mutex(const mutex&) = delete;
    mutex& operator=(const mutex&) = delete;
    void lock();
    bool try_lock();
    void unlock();

    using native_handle_type = implementation-defined; // see 32.2.3
    native_handle_type native_handle(); // see 32.2.3
};
```

The class `mutex` provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a mutex object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`) until the owning thread has released ownership with a call to `unlock()`.

[Note: After a thread A has called `unlock()`, releasing a mutex, it is possible for another thread B to lock the same mutex, observe that it is no longer in use, unlock it, and destroy it, before thread A appears to have returned from its unlock call. Implementations are required to handle such scenarios correctly, as long as thread A doesn’t access the mutex after the unlock call returns. These cases typically occur when a reference-counted object contains a mutex that is used to protect the reference count. — end note]

The class `mutex` meets all of the mutex requirements (32.5.3). It is a standard-layout class (11.2).

[Note: A program can deadlock if the thread that owns a mutex object calls `lock()` on that object. If the implementation can detect the deadlock, a `resource_deadlock_would_occur` error condition might be observed. — end note]

The behavior of a program is undefined if it destroys a `mutex` object owned by any thread or a thread terminates while owning a `mutex` object.

### 32.5.3.2.2 Class `recursive_mutex`

```cpp
class recursive_mutex {
public:
    recursive_mutex();
    ~recursive_mutex();
    recursive_mutex(const recursive_mutex&) = delete;
    recursive_mutex& operator=(const recursive_mutex&) = delete;

    void lock();
    bool try_lock() noexcept;
    void unlock();

    using native_handle_type = implementation-defined; // see 32.2.3
    native_handle_type native_handle(); // see 32.2.3
};
```
The class `recursive_mutex` provides a recursive mutex with exclusive ownership semantics. If one thread owns a `recursive_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`) until the first thread has completely released ownership.

The class `recursive_mutex` meets all of the mutex requirements (32.5.3). It is a standard-layout class (11.2).

A thread that owns a `recursive_mutex` object may acquire additional levels of ownership by calling `lock()` or `try_lock()` on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a `recursive_mutex` object, additional calls to `try_lock()` fail, and additional calls to `lock()` throw an exception of type `system_error`. A thread shall call `unlock()` once for each level of ownership acquired by calls to `lock()` and `try_lock()`. Only when all levels of ownership have been released may ownership be acquired by another thread.

The behavior of a program is undefined if:

1. it destroys a `recursive_mutex` object owned by any thread or
2. a thread terminates while owning a `recursive_mutex` object.

### 32.5.3.3 Timed mutex types

The `timed_mutex` types are the standard library types `timed_mutex`, `recursive_timed_mutex`, and `shared_timed_mutex`. They meet the requirements set out below. In this description, `m` denotes an object of a mutex type, `rel_time` denotes an object of an instantiation of `duration` (27.5), and `abs_time` denotes an object of an instantiation of `time_point` (27.6).

The timed mutex types meet the `Cpp17TimedLockable` requirements (32.2.5.4).

The expression `m.try_lock_for(rel_time)` is well-formed and has the following semantics:

1. **Preconditions**: If `m` is of type `timed_mutex` or `shared_timed_mutex`, the calling thread does not own the mutex.
2. **Effects**: The function attempts to obtain ownership of the mutex within the relative timeout (32.2.4) specified by `rel_time`. If the time specified by `rel_time` is less than or equal to `rel_time.zero()`, the function attempts to obtain ownership without blocking (as if by calling `try_lock()`). The function returns within the timeout specified by `rel_time` only if it has obtained ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]
3. **Return type**: `bool`.
4. **Returns**: `true` if ownership was obtained, otherwise `false`.
5. **Synchronization**: If `try_lock_for()` returns `true`, prior `unlock()` operations on the same object synchronize with (6.9.2) this operation.
6. **Throws**: Timeout-related exceptions (32.2.4).

The expression `m.try_lock_until(abs_time)` is well-formed and has the following semantics:

1. **Preconditions**: If `m` is of type `timed_mutex` or `shared_timed_mutex`, the calling thread does not own the mutex.
2. **Effects**: The function attempts to obtain ownership of the mutex. If `abs_time` has already passed, the function attempts to obtain ownership without blocking (as if by calling `try_lock()`). The function returns before the absolute timeout (32.2.4) specified by `abs_time` only if it has obtained ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]
3. **Return type**: `bool`.
4. **Returns**: `true` if ownership was obtained, otherwise `false`.
5. **Synchronization**: If `try_lock_until()` returns `true`, prior `unlock()` operations on the same object synchronize with (6.9.2) this operation.
6. **Throws**: Timeout-related exceptions (32.2.4).

§ 32.5.3.3
32.5.3.3.1 Class timed_mutex

namespace std {
    class timed_mutex {
    public:
        timed_mutex();
        ~timed_mutex();

        timed_mutex(const timed_mutex&) = delete;
        timed_mutex& operator=(const timed_mutex&) = delete;

        void lock(); // blocking
        bool try_lock();
        template<class Rep, class Period>
            bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
        template<class Clock, class Duration>
            bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
        void unlock();

        using native_handle_type = implementation-defined; // see 32.2.3
        native_handle_type native_handle(); // see 32.2.3
    };}

The class timed_mutex provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a timed_mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock()) or block (for lock(), try_lock_for(), and try_lock_until()) until the owning thread has released ownership with a call to unlock() or the call to try_lock_for() or try_lock_until() times out (having failed to obtain ownership).

The class timed_mutex meets all of the timed mutex requirements (32.5.3.3). It is a standard-layout class (11.2).

The behavior of a program is undefined if:

- it destroys a timed_mutex object owned by any thread,
- a thread that owns a timed_mutex object calls lock(), try_lock(), try_lock_for(), or try_lock_until() on that object, or
- a thread terminates while owning a timed_mutex object.

32.5.3.3.2 Class recursive_timed_mutex

namespace std {
    class recursive_timed_mutex {
    public:
        recursive_timed_mutex();
        ~recursive_timed_mutex();

        recursive_timed_mutex(const recursive_timed_mutex&) = delete;
        recursive_timed_mutex& operator=(const recursive_timed_mutex&) = delete;

        void lock(); // blocking
        bool try_lock() noexcept;
        template<class Rep, class Period>
            bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
        template<class Clock, class Duration>
            bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
        void unlock();

        using native_handle_type = implementation-defined; // see 32.2.3
        native_handle_type native_handle(); // see 32.2.3
    };}

The class recursive_timed_mutex provides a recursive mutex with exclusive ownership semantics. If one thread owns a recursive_timed_mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock()) or block (for lock(), try_lock_for(), and try_lock_until()) until the owning thread has
completely released ownership or the call to try_lock_for() or try_lock_until() times out (having failed to obtain ownership).

2 The class `recursive_timed_mutex` meets all of the timed mutex requirements (32.5.3.3). It is a standard-layout class (11.2).

3 A thread that owns a `recursive_timed_mutex` object may acquire additional levels of ownership by calling lock(), try_lock(), try_lock_for(), or try_lock_until() on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a `recursive_timed_mutex` object, additional calls to try_lock(), try_lock_for(), or try_lock_until() fail, and additional calls to lock() throw an exception of type system_error. A thread shall call unlock() once for each level of ownership acquired by calls to lock(), try_lock(), try_lock_for(), and try_lock_until(). Only when all levels of ownership have been released may ownership of the object be acquired by another thread.

4 The behavior of a program is undefined if:

   (4.1) — it destroys a `recursive_timed_mutex` object owned by any thread, or

   (4.2) — a thread terminates while owning a `recursive_timed_mutex` object.

### 32.5.3.4 Shared mutex types

The standard library types `shared_mutex` and `shared_timed_mutex` are shared mutex types. Shared mutex types meet the requirements of mutex types (32.5.3.2) and additionally meet the requirements set out below. In this description, `m` denotes an object of a shared mutex type.

2 In addition to the exclusive lock ownership mode specified in 32.5.3.2, shared mutex types provide a shared lock ownership mode. Multiple execution agents can simultaneously hold a shared lock ownership of a shared mutex type. But no execution agent holds a shared lock while another execution agent holds an exclusive lock on the same shared mutex type, and vice-versa. The maximum number of execution agents which can share a shared lock on a single shared mutex type is unspecified, but is at least 10000. If more than the maximum number of execution agents attempt to obtain a shared lock, the excess execution agents block until the number of shared locks are reduced below the maximum amount by other execution agents releasing their shared lock.

3 The expression `m.lock_shared()` is well-formed and has the following semantics:

   **Preconditions:** The calling thread has no ownership of the mutex.

   **Effects:** Blocks the calling thread until shared ownership of the mutex can be obtained for the calling thread. If an exception is thrown then a shared lock has not been acquired for the current thread.

   **Postconditions:** The calling thread has a shared lock on the mutex.

   **Return type:** void.

   **Synchronization:** Prior unlock() operations on the same object synchronize with (6.9.2) this operation.

   **Throws:** system_error when an exception is required (32.2.2).

   **Error conditions:**

   - operation_not_permitted — if the thread does not have the privilege to perform the operation.
   - resource_deadlock_would_occur — if the implementation detects that a deadlock would occur.

10 The expression `m.unlock_shared()` is well-formed and has the following semantics:

   **Preconditions:** The calling thread holds a shared lock on the mutex.

   **Effects:** Releases a shared lock on the mutex held by the calling thread.

   **Return type:** void.

   **Synchronization:** This operation synchronizes with (6.9.2) subsequent lock() operations that obtain ownership on the same object.

   **Throws:** Nothing.

17 The expression `m.try_lock_shared()` is well-formed and has the following semantics:

   **Preconditions:** The calling thread has no ownership of the mutex.

   **Effects:** Attempts to obtain shared ownership of the mutex for the calling thread without blocking. If shared ownership is not obtained, there is no effect and try_lock_shared() immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread.

§ 32.5.3.4
Return type: bool.

Returns: true if the shared ownership lock was acquired, false otherwise.

Synchronization: If try_lock_shared() returns true, prior unlock() operations on the same object synchronize with (6.9.2) this operation.

Throws: Nothing.

32.5.3.4.1 Class shared_mutex

namespace std {
    class shared_mutex {
        public:
            shared_mutex();
            ~shared_mutex();
            shared_mutex(const shared_mutex&) = delete;
            shared_mutex& operator=(const shared_mutex&) = delete;
            // exclusive ownership
            void lock(); // blocking
            bool try_lock();
            void unlock();
            // shared ownership
            void lock_shared(); // blocking
            bool try_lock_shared();
            void unlock_shared();
            using native_handle_type = implementation-defined; // see 32.2.3
            native_handle_type native_handle(); // see 32.2.3
        }
    }
}

The class shared_mutex provides a non-recursive mutex with shared ownership semantics.

The class shared_mutex meets all of the shared mutex requirements (32.5.3.4). It is a standard-layout class (11.2).

The behavior of a program is undefined if:

1. it destroys a shared_mutex object owned by any thread,
2. a thread attempts to recursively gain any ownership of a shared_mutex, or
3. a thread terminates while possessing any ownership of a shared_mutex.

shared_mutex may be a synonym for shared_timed_mutex.

32.5.3.5 Shared timed mutex types

The standard library type shared_timed_mutex is a shared timed mutex type. Shared timed mutex types meet the requirements of timed mutex types (32.5.3.3), shared mutex types (32.5.3.4), and additionally meet the requirements set out below. In this description, m denotes an object of a shared timed mutex type, rel_type denotes an object of an instantiation of duration (27.5), and abs_time denotes an object of an instantiation of time_point (27.6).

The expression m.try_lock_shared_for(rel_time) is well-formed and has the following semantics:

Preconditions: The calling thread has no ownership of the mutex.

Effects: Attempts to obtain shared lock ownership for the calling thread within the relative timeout (32.2.4) specified by rel_time. If the time specified by rel_time is less than or equal to rel_time.zero(), the function attempts to obtain ownership without blocking (as if by calling try_lock_shared()). The function returns within the timeout specified by rel_time only if it has obtained shared ownership of the mutex object. [Note: As with try_lock(), there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note] If an exception is thrown then a shared lock has not been acquired for the current thread.

Return type: bool.

Returns: true if the shared lock was acquired, false otherwise.
Synchronization: If \( \text{try\_lock\_shared\_for}() \) returns true, prior unlock() operations on the same object synchronize with (6.9.2) this operation.

Throws: Timeout-related exceptions (32.2.4).

The expression \( m \text{.try\_lock\_shared\_until}(\text{abs\_time}) \) is well-formed and has the following semantics:

Preconditions: The calling thread has no ownership of the mutex.

Effects: The function attempts to obtain shared ownership of the mutex. If \( \text{abs\_time} \) has already passed, the function attempts to obtain shared ownership without blocking (as if by calling \( \text{try\_lock\_shared}() \)). The function returns before the absolute timeout (32.2.4) specified by \( \text{abs\_time} \) only if it has obtained shared ownership of the mutex object. [Note: As with \( \text{try\_lock}() \), there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note] If an exception is thrown then a shared lock has not been acquired for the current thread.

Return type: bool.

Returns: true if the shared lock was acquired, false otherwise.

Synchronization: If \( \text{try\_lock\_shared\_until}() \) returns true, prior unlock() operations on the same object synchronize with (6.9.2) this operation.

Throws: Timeout-related exceptions (32.2.4).

32.5.3.5.1 Class \texttt{shared\_timed\_mutex} [thread.sharedtimedmutex.class]

namespace std {
    class shared\_timed\_mutex {
        public:
            shared\_timed\_mutex();
            ′shared\_timed\_mutex();
            shared\_timed\_mutex(const shared\_timed\_mutex&) = delete;
            shared\_timed\_mutex& operator=(const shared\_timed\_mutex&) = delete;

            // exclusive ownership
            void lock(); // blocking
            bool try\_lock();
            template<class Rep, class Period>
                bool try\_lock\_for(const \text{chrono}\::\text{duration}<Rep, Period>& rel\_time);
            template<class Clock, class Duration>
                bool try\_lock\_until(const \text{chrono}\::\text{time\_point}<Clock, Duration>& abs\_time);
            void unlock();

            // shared ownership
            void lock\_shared(); // blocking
            bool try\_lock\_shared();
            template<class Rep, class Period>
                bool try\_lock\_shared\_for(const \text{chrono}\::\text{duration}<Rep, Period>& rel\_time);
            template<class Clock, class Duration>
                bool try\_lock\_shared\_until(const \text{chrono}\::\text{time\_point}<Clock, Duration>& abs\_time);
            void unlock\_shared();
    }
}

The class \texttt{shared\_timed\_mutex} provides a non-recursive mutex with shared ownership semantics.

The class \texttt{shared\_timed\_mutex} meets all of the shared timed mutex requirements (32.5.3.5). It is a standard-layout class (11.2).

The behavior of a program is undefined if:

- it destroys a \texttt{shared\_timed\_mutex} object owned by any thread,
- a thread attempts to recursively gain any ownership of a \texttt{shared\_timed\_mutex}, or
- a thread terminates while possessing any ownership of a \texttt{shared\_timed\_mutex}.
32.5.4 Locks

A lock is an object that holds a reference to a lockable object and may unlock the lockable object during the lock’s destruction (such as when leaving block scope). An execution agent may use a lock to aid in managing ownership of a lockable object in an exception safe manner. A lock is said to own a lockable object if it is currently managing the ownership of that lockable object for an execution agent. A lock does not manage the lifetime of the lockable object it references. [Note: Locks are intended to ease the burden of unlocking the lockable object under both normal and exceptional circumstances. — end note]

Some lock constructors take tag types which describe what should be done with the lockable object during the lock’s construction.

```cpp
namespace std {
    struct defer_lock_t {}; // do not acquire ownership of the mutex
    struct try_to_lock_t {}; // try to acquire ownership of the mutex
    // without blocking
    struct adopt_lock_t {}; // assume the calling thread has already
    // obtained mutex ownership and manage it

    inline constexpr defer_lock_t defer_lock { };
    inline constexpr try_to_lock_t try_to_lock { }; // try to lock
    inline constexpr adopt_lock_t adopt_lock { }; // adopt lock
}
```

32.5.4.1 Class template lock_guard

```cpp
namespace std {
    template<class Mutex>
    class lock_guard {
    public:
        using mutex_type = Mutex;

        explicit lock_guard(mutex_type& m);
        lock_guard(mutex_type& m, adopt_lock_t);
        ~lock_guard();

        lock_guard(const lock_guard&) = delete;
        lock_guard& operator=(const lock_guard&) = delete;

    private:
        mutex_type& pm; // exposition only
    };
}
```

An object of type lock_guard controls the ownership of a lockable object within a scope. A lock_guard object maintains ownership of a lockable object throughout the lock_guard object’s lifetime (6.7.3). The behavior of a program is undefined if the lockable object referenced by pm does not exist for the entire lifetime of the lock_guard object. The supplied Mutex type shall meet the Cpp17BasicLockable requirements (32.2.5.2).

```cpp
explicit lock_guard(mutex_type& m);
```

1 Preconditions: If mutex_type is not a recursive mutex, the calling thread does not own the mutex m.

2 Effects: Initializes pm with m. Calls m.lock().

```cpp
lock_guard(mutex_type& m, adopt_lock_t);
```

4 Preconditions: The calling thread owns the mutex m.

5 Effects: Initializes pm with m.

6 Throws: Nothing.

```cpp
~lock_guard();
```

7 Effects: As if by pm.unlock().
32.5.4.2 Class template `scoped_lock`  

```cpp
namespace std {
    template<class... MutexTypes>
    class scoped_lock {
    public:
        using mutex_type = Mutex;  // If MutexTypes... consists of the single type Mutex
        explicit scoped_lock(MutexTypes&... m);
        explicit scoped_lock(adopt_lock_t, MutexTypes&... m);
        ~scoped_lock();
        scoped_lock(const scoped_lock&) = delete;
        scoped_lock& operator=(const scoped_lock&) = delete;

    private:
        tuple<MutexTypes&...> pm;  // exposition only
    }
}
```

An object of type `scoped_lock` controls the ownership of lockable objects within a scope. A `scoped_lock` object maintains ownership of lockable objects throughout the `scoped_lock` object’s lifetime (6.7.3). The behavior of a program is undefined if the lockable objects referenced by `pm` do not exist for the entire lifetime of the `scoped_lock` object. When `sizeof...(MutexTypes)` is 1, the supplied `Mutex` type shall meet the `Cpp17BasicLockable` requirements (32.2.5.2). Otherwise, each of the mutex types shall meet the `Cpp17Lockable` requirements (32.2.5.3).

```cpp
explicit scoped_lock(MutexTypes&... m);
```

**Preconditions:** If a `MutexTypes` type is not a recursive mutex, the calling thread does not own the corresponding mutex element of `m`.

**Effects:** Initializes `pm` with `tie(m...)`. Then if `sizeof...(MutexTypes)` is 0, no effects. Otherwise if `sizeof...(MutexTypes)` is 1, then `m.lock()`. Otherwise, `lock(m...)`.

```cpp
explicit scoped_lock(adopt_lock_t, MutexTypes&... m);
```

**Preconditions:** The calling thread owns all the mutexes in `m`.

**Effects:** Initializes `pm` with `tie(m...)`.

**Throws:** Nothing.

```cpp
~scoped_lock();
```

**Effects:** For all `i` in `[0, sizeof...(MutexTypes))`, `get<i>(pm).unlock()`.

32.5.4.3 Class template `unique_lock`  

```cpp
namespace std {
    template<class Mutex>
    class unique_lock {
    public:
        using mutex_type = Mutex;

        // 32.5.4.3.1, construct/copy/destroy
        unique_lock() noexcept;
        explicit unique_lock(mutex_type& m);
        unique_lock(mutex_type& m, defer_lock_t) noexcept;
        unique_lock(mutex_type& m, try_to_lock_t);
        unique_lock(mutex_type& m, adopt_lock_t);
        template<class Clock, class Duration>
        unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
        template<class Rep, class Period>
        unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
        ~unique_lock();

        unique_lock(const unique_lock&) = delete;
        unique_lock& operator=(const unique_lock&) = delete;
    }
}
```
unique_lock(unique_lock&& u) noexcept;
unique_lock& operator=(unique_lock&& u);

// 32.5.4.3.2, locking
void lock();
bool try_lock();

template<class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

template<class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

void unlock();

// 32.5.4.3.3, modifiers
void swap(unique_lock& u) noexcept;
mutex_type* release() noexcept;

// 32.5.4.3.4, observers
bool owns_lock() const noexcept;
explicit operator bool () const noexcept;
mutex_type* mutex() const noexcept;

private:
mutex_type* pm;        // exposition only
bool owns;             // exposition only
};

template<class Mutex>
void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;

1 An object of type \texttt{unique\_lock} controls the ownership of a lockable object within a scope. Ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another \texttt{unique\_lock} object. Objects of type \texttt{unique\_lock} are not copyable but are movable. The behavior of a program is undefined if the contained pointer \texttt{pm} is not null and the lockable object pointed to by \texttt{pm} does not exist for the entire remaining lifetime (6.7.3) of the \texttt{unique\_lock} object. The supplied \texttt{Mutex} type shall meet the \texttt{Cpp17BasicLockable} requirements (32.2.5.2).

2 [Note: \texttt{unique\_lock<Mutex>} meets the \texttt{Cpp17BasicLockable} requirements. If \texttt{Mutex} meets the \texttt{Cpp17Lockable} requirements (32.2.5.3), \texttt{unique\_lock<Mutex>} also meets the \texttt{Cpp17Lockable} requirements; if \texttt{Mutex} meets the \texttt{Cpp17TimedLockable} requirements (32.2.5.4), \texttt{unique\_lock<Mutex>} also meets the \texttt{Cpp17TimedLockable} requirements. – end note]

32.5.4.3.1 Constructors, destructor, and assignment

unique_lock() noexcept;

1 Postconditions: \texttt{pm == 0} and \texttt{owns == false}.

explicit unique_lock(mutex_type& m);

2 Preconditions: If \texttt{mutex\_type} is not a recursive mutex the calling thread does not own the mutex.

3 Effects: Calls \texttt{m.lock()}.

4 Postconditions: \texttt{pm == addressof(m)} and \texttt{owns == true}.

unique_lock(mutex_type& m, defer_lock_t) noexcept;

5 Postconditions: \texttt{pm == addressof(m)} and \texttt{owns == false}.

unique_lock(mutex_type& m, try_to_lock_t);

6 Preconditions: The supplied \texttt{Mutex} type meets the \texttt{Cpp17Lockable} requirements (32.2.5.3). If \texttt{mutex\_type} is not a recursive mutex the calling thread does not own the mutex.

7 Effects: Calls \texttt{m.try\_lock()}.
8  Postconditions: \( \text{pm} == \text{addressof}(m) \) and \( \text{owns} == \text{res} \), where \( \text{res} \) is the value returned by the call to \( m.\text{try_lock()} \).

9  `unique_lock(mutex_type& m, adopt_lock_t);`

9  Preconditions: The calling thread owns the mutex.
10  Postconditions: \( \text{pm} == \text{addressof}(m) \) and \( \text{owns} == \text{true} \).
11  Throws: Nothing.

12  template<class Clock, class Duration>
13  `unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);`
14  Preconditions: If \( \text{mutex_type} \) is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type meets the \textit{Cpp17TimedLockable} requirements (32.2.5.4).
15  Effects: Calls \( m.\text{try_lock_until}(\text{abs_time}) \).
16  Postconditions: \( \text{pm} == \text{addressof}(m) \) and \( \text{owns} == \text{res} \), where \( \text{res} \) is the value returned by the call to \( m.\text{try_lock_until}(\text{abs_time}) \).

17  template<class Rep, class Period>
18  `unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);`
19  Preconditions: If \( \text{mutex_type} \) is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type meets the \textit{Cpp17TimedLockable} requirements (32.2.5.4).
20  Effects: Calls \( m.\text{try_lock_for}(\text{rel_time}) \).
21  Postconditions: \( \text{pm} == \text{addressof}(m) \) and \( \text{owns} == \text{res} \), where \( \text{res} \) is the value returned by the call to \( m.\text{try_lock_for}(\text{rel_time}) \).

22  `unique_lock(unique_lock&& u) noexcept;`
23  Postconditions: \( \text{pm} == \text{u_p.pm} \) and \( \text{owns} == \text{u_p.owns} \) (where \( \text{u_p} \) is the state of \( \text{u} \) just prior to this construction), \( \text{u.pm} == 0 \) and \( \text{u.owns} == \text{false} \).

24  `unique_lock& operator=(unique_lock&& u);`
25  Effects: If \( \text{owns} \) calls \( \text{pm->unlock()} \).
26  Postconditions: \( \text{pm} == \text{u_p.pm} \) and \( \text{owns} == \text{u_p.owns} \) (where \( \text{u_p} \) is the state of \( \text{u} \) just prior to this construction), \( \text{u.pm} == 0 \) and \( \text{u.owns} == \text{false} \).
27  [Note: With a recursive mutex it is possible for both \*this and \( \text{u} \) to own the same mutex before the assignment. In this case, \*this will own the mutex after the assignment and \( \text{u} \) will not. — end note]
28  Throws: Nothing.

29  ~`unique_lock();`
30  Effects: If \( \text{owns} \) calls \( \text{pm->unlock()} \).

### 32.5.4.3.2 Locking

32.5.4.3.2.1 [thread.lock.unique_locking]

33  `void lock();`
34  Effects: As if by \( \text{pm->lock()} \).
35  Postconditions: \( \text{owns} == \text{true} \).
36  Throws: Any exception thrown by \( \text{pm->lock()} \), \textit{system_error} when an exception is required (32.2.2).
37  Error conditions:
38    - `operation_not_permitted` — if \( \text{pm} \) is \textit{nullptr}.
39    - `resource_deadlock_would_occur` — if on entry \( \text{owns} \) is \text{true}.

39  `bool try_lock();`
40  Preconditions: The supplied Mutex meets the \textit{Cpp17Lockable} requirements (32.2.5.3).
41  Effects: As if by \( \text{pm->try_lock()} \).
42  Postconditions: \( \text{owns} == \text{res} \), where \( \text{res} \) is the value returned by the call to \( \text{try_lock()} \).
Returns: The value returned by the call to try_lock().

Throws: Any exception thrown by pm->try_lock(). system_error when an exception is required (32.2.2).

Error conditions:

(10.1) operation_not_permitted — if pm is nullptr.

(10.2) resource_deadlock_would_occur — if on entry owns is true.

template<class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

Preconditions: The supplied Mutex type meets the Cpp17TimedLockable requirements (32.2.5.4).

Effects: As if by pm->try_lock_until(abs_time).

Postconditions: owns == res, where res is the value returned by the call to try_lock_until(abs_time).

Returns: The value returned by the call to try_lock_until(abs_time).

Throws: Any exception thrown by pm->try_lock_until(). system_error when an exception is required (32.2.2).

Error conditions:

(16.1) operation_not_permitted — if pm is nullptr.

(16.2) resource_deadlock_would_occur — if on entry owns is true.

template<class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

Preconditions: The supplied Mutex type meets the Cpp17TimedLockable requirements (32.2.5.4).

Effects: As if by pm->try_lock_for(rel_time).

Postconditions: owns == res, where res is the value returned by the call to try_lock_for(rel_time).

Returns: The value returned by the call to try_lock_for(rel_time).

Throws: Any exception thrown by pm->try_lock_for(). system_error when an exception is required (32.2.2).

Error conditions:

(22.1) operation_not_permitted — if pm is nullptr.

(22.2) resource_deadlock_would_occur — if on entry owns is true.

void unlock();

Effects: As if by pm->unlock().

Postconditions: owns == false.

Throws: system_error when an exception is required (32.2.2).

Error conditions:

(26.1) operation_not_permitted — if on entry owns is false.

32.5.4.3.3 Modifiers

void swap(unique_lock& u) noexcept;

Effects: Swaps the data members of *this and u.

mutex_type* release() noexcept;

Postconditions: pm == 0 and owns == false.

Returns: The previous value of pm.

template<class Mutex>
void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;

Effects: As if by x.swap(y).
32.5.4.3.4 Observers

```cpp
bool owns_lock() const noexcept;

1 Returns: owns.
```

```cpp
explicit operator bool() const noexcept;

2 Returns: owns.
```

```cpp
mutex_type *mutex() const noexcept;

3 Returns: pm.
```

32.5.4.4 Class template shared_lock

```cpp
namespace std {

template<class Mutex>
class shared_lock {

public:

using mutex_type = Mutex;

23.5.4.4.1, construct/copy/destroy

shared_lock() noexcept;

explicit shared_lock(mutex_type& m);   // blocking

shared_lock(mutex_type& m, defer_lock_t) noexcept;

shared_lock(mutex_type& m, try_to_lock_t);

shared_lock(mutex_type& m, adopt_lock_t);

template<class Clock, class Duration>

shared_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);

template<class Rep, class Period>

shared_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);

~shared_lock();

shared_lock(const shared_lock&) = delete;

shared_lock& operator=(const shared_lock&) = delete;

shared_lock(shared_lock&& u) noexcept;

shared_lock& operator=(shared_lock&& u) noexcept;

23.5.4.4.2, locking

void lock();   // blocking

bool try_lock();

template<class Rep, class Period>

bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

template<class Clock, class Duration>

bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

void unlock();

23.5.4.4.3, modifiers

void swap(shared_lock& u) noexcept;

mutex_type* release() noexcept;

23.5.4.4.4, observers

bool owns_lock() const noexcept;

explicit operator bool () const noexcept;

mutex_type* mutex() const noexcept;

private:

mutex_type* pm;   // exposition only

bool owns;   // exposition only

};

template<class Mutex>

void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
}
```
An object of type `shared_lock` controls the shared ownership of a lockable object within a scope. Shared ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another `shared_lock` object. Objects of type `shared_lock` are not copyable but are movable. The behavior of a program is undefined if the contained pointer `pm` is not null and the lockable object pointed to by `pm` does not exist for the entire remaining lifetime (6.7.3) of the `shared_lock` object. The supplied `Mutex` type shall meet the shared mutex requirements (32.5.3.5).

[Note: `shared_lock<Mutex>` meets the Cpp17TimedLockable requirements (32.2.5.4). — end note]

### 32.5.4.4.1 Constructors, destructor, and assignment

#### [thread.lock.shared.cons]

```cpp
shared_lock() noexcept;
Postconditions: pm == nullptr and owns == false.

explicit shared_lock(mutex_type& m);
Preconditions: The calling thread does not own the mutex for any ownership mode.
Effects: Calls m.lock_shared().
Postconditions: pm == addressof(m) and owns == true.

shared_lock(mutex_type& m, defer_lock_t) noexcept;
Postconditions: pm == addressof(m) and owns == false.

shared_lock(mutex_type& m, try_to_lock_t);
Preconditions: The calling thread does not own the mutex for any ownership mode.
Effects: Calls m.try_lock_shared().
Postconditions: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared().

shared_lock(mutex_type& m, adopt_lock_t);
Preconditions: The calling thread has shared ownership of the mutex.
Postconditions: pm == addressof(m) and owns == true.

template<class Clock, class Duration>
shared_lock(mutex_type& m,
const chrono::time_point<Clock, Duration>& abs_time);
Preconditions: The calling thread does not own the mutex for any ownership mode.
Effects: Calls m.try_lock_shared_until(abs_time).
Postconditions: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared_until(abs_time).

template<class Rep, class Period>
shared_lock(mutex_type& m,
const chrono::duration<Rep, Period>& rel_time);
Preconditions: The calling thread does not own the mutex for any ownership mode.
Effects: Calls m.try_lock_shared_for(rel_time).
Postconditions: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared_for(rel_time).

~shared_lock();
Effects: If owns calls pm->unlock_shared().

shared_lock(shared_lock&& sl) noexcept;
Postconditions: pm == sl.pm and owns == sl.owns (where sl is the state of sl just prior to this construction), sl.pm == nullptr and sl.owns == false.

shared_lock& operator=(shared_lock&& sl) noexcept;
Effects: If owns calls pm->unlock_shared().
```
Postconditions: \( pm == sl_p.pm \) and \( owns == sl_p.owns \) (where \( sl_p \) is the state of \( sl \) just prior to this assignment), \( sl.pm == \text{nullptr} \) and \( sl.owns == \text{false} \).

### 32.5.4.4.2 Locking

```
void lock();
```

**Effects:** As if by \( pm->\text{lock\_shared}() \).

**Postconditions:** \( owns == \text{true} \).

**Throws:** Any exception thrown by \( pm->\text{lock\_shared}() \). \( \text{system\_error} \) when an exception is required (32.2.2).

**Error conditions:**
- \( \text{operation\_not\_permitted} \) — if \( pm \) is \( \text{nullptr} \).
- \( \text{resource\_deadlock\_would\_occur} \) — if on entry \( owns \) is \( \text{true} \).

```
bool try_lock();
```

**Effects:** As if by \( pm->\text{try\_lock\_shared}() \).

**Postconditions:** \( owns == res \), where \( res \) is the value returned by the call to \( pm->\text{try\_lock\_shared}() \).

**Returns:** The value returned by the call to \( pm->\text{try\_lock\_shared}() \).

**Throws:** Any exception thrown by \( pm->\text{try\_lock\_shared}() \). \( \text{system\_error} \) when an exception is required (32.2.2).

**Error conditions:**
- \( \text{operation\_not\_permitted} \) — if \( pm \) is \( \text{nullptr} \).
- \( \text{resource\_deadlock\_would\_occur} \) — if on entry \( owns \) is \( \text{true} \).

```template<class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
```

**Effects:** As if by \( pm->\text{try\_lock\_shared\_until}(abs\_time) \).

**Postconditions:** \( owns == res \), where \( res \) is the value returned by the call to \( pm->\text{try\_lock\_shared\_until}(abs\_time) \).

**Returns:** The value returned by the call to \( pm->\text{try\_lock\_shared\_until}(abs\_time) \).

**Throws:** Any exception thrown by \( pm->\text{try\_lock\_shared\_until}(abs\_time) \). \( \text{system\_error} \) when an exception is required (32.2.2).

**Error conditions:**
- \( \text{operation\_not\_permitted} \) — if \( pm \) is \( \text{nullptr} \).
- \( \text{resource\_deadlock\_would\_occur} \) — if on entry \( owns \) is \( \text{true} \).

```template<class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
```

**Effects:** As if by \( pm->\text{try\_lock\_shared\_for}(rel\_time) \).

**Postconditions:** \( owns == res \), where \( res \) is the value returned by the call to \( pm->\text{try\_lock\_shared\_for}(rel\_time) \).

**Returns:** The value returned by the call to \( pm->\text{try\_lock\_shared\_for}(rel\_time) \).

**Throws:** Any exception thrown by \( pm->\text{try\_lock\_shared\_for}(rel\_time) \). \( \text{system\_error} \) when an exception is required (32.2.2).

**Error conditions:**
- \( \text{operation\_not\_permitted} \) — if \( pm \) is \( \text{nullptr} \).
- \( \text{resource\_deadlock\_would\_occur} \) — if on entry \( owns \) is \( \text{true} \).

```void unlock();
```

**Effects:** As if by \( pm->\text{unlock\_shared}() \).

**Postconditions:** \( owns == \text{false} \).
Throws: system_error when an exception is required (32.2.2).

Error conditions:
— operation_not_permitted — if on entry owns is false.

### 32.5.4.3 Modifiers

```cpp
void swap(shared_lock& sl) noexcept;
```

**Effects:** Swaps the data members of *this and sl.

```cpp
mutex_type* release() noexcept;
```

**Postconditions:** pm == nullptr and owns == false.

**Returns:** The previous value of pm.

```cpp
template<class Mutex>
void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
```

**Effects:** As if by x.swap(y).

### 32.5.4.4 Observers

```cpp
bool owns_lock() const noexcept;
```

**Returns:** owns.

```cpp
explicit operator bool() const noexcept;
```

**Returns:** owns.

```cpp
mutex_type* mutex() const noexcept;
```

**Returns:** pm.

### 32.5.5 Generic locking algorithms

```cpp
template<class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
```

**Preconditions:** Each template parameter type meets the Cpp17Lockable requirements. [Note: The unique_lock class template meets these requirements when suitably instantiated. — end note]

**Effects:** Calls try_lock() for each argument in order beginning with the first until all arguments have been processed or a call to try_lock() fails, either by returning false or by throwing an exception. If a call to try_lock() fails, unlock() is called for all prior arguments with no further calls to try_lock().

**Returns:** -1 if all calls to try_lock() returned true, otherwise a zero-based index value that indicates the argument for which try_lock() returned false.

```cpp
template<class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);
```

**Preconditions:** Each template parameter type meets the Cpp17Lockable requirements. [Note: The unique_lock class template meets these requirements when suitably instantiated. — end note]

**Effects:** All arguments are locked via a sequence of calls to lock(), try_lock(), or unlock() on each argument. The sequence of calls does not result in deadlock, but is otherwise unspecified. [Note: A deadlock avoidance algorithm such as try-and-back-off must be used, but the specific algorithm is not specified to avoid over-constraining implementations. — end note] If a call to lock() or try_lock() throws an exception, unlock() is called for any argument that had been locked by a call to lock() or try_lock().

### 32.5.6 Call once

### 32.5.6.1 Struct once_flag

```cpp
namespace std {
    struct once_flag {
        constexpr once_flag() noexcept;
        once_flag(const once_flag&) = delete;
        once_flag& operator=(const once_flag&) = delete;
    }
}
```

§ 32.5.6.1
The class `once_flag` is an opaque data structure that `call_once` uses to initialize data without causing a data race or deadlock.

```cpp
constexpr once_flag() noexcept;
```

**Synchronization:** The construction of a `once_flag` object is not synchronized.

**Postconditions:** The object’s internal state is set to indicate to an invocation of `call_once` with the object as its initial argument that no function has been called.

### 32.5.6.2 Function `call_once`

```cpp
template<class Callable, class... Args>
void call_once(once_flag& flag, Callable&& func, Args&&... args);
```

**Mandates:**

```cpp
is_invocable_v<Callable, Args...> is true.
```

**Effects:** An execution of `call_once` that does not call its `func` is a passive execution. An execution of `call_once` that calls its `func` is an active execution. An active execution calls `INVOKE(std::forward<Callable>(func), std::forward<Args>(arg)...).` If such a call to `func` throws an exception the execution is exceptional, otherwise it is returning. An exceptional execution propagates the exception to the caller of `call_once`. Among all executions of `call_once` for any given `once_flag`: at most one is a returning execution; if there is a returning execution, it is the last active execution; and there are passive executions only if there is a returning execution. [Note: Passive executions allow other threads to reliably observe the results produced by the earlier returning execution. — end note]

**Synchronization:** For any given `once_flag`: all active executions occur in a total order; completion of an active execution synchronizes with (6.9.2) the start of the next one in this total order; and the returning execution synchronizes with the return from all passive executions.

**Throws:** `system_error` when an exception is required (32.2.2), or any exception thrown by `func`.

### Example:

```cpp
// global flag, regular function
void init();
std::once_flag flag;

void f() {
    std::call_once(flag, init);
}

// function static flag, function object
struct initializer {
    void operator()();
};

void g() {
    static std::once_flag flag2;
    std::call_once(flag2, initializer());
}

// object flag, member function
class information {
    std::once_flag verified;
    void verifier();
    public:
        void verify() { std::call_once(verified, &information::verifier, *this); }
};
```

### 32.6 Condition variables

Condition variables provide synchronization primitives used to block a thread until notified by some other thread that some condition is met or until a system time is reached. Class `condition_variable` provides a condition variable that can only wait on an object of type `unique_lock<mutex>`, allowing the implementation to be more efficient. Class `condition_variable_any` provides a general condition variable that can wait on objects of user-supplied lock types.
Condition variables permit concurrent invocation of the `wait`, `wait_for`, `wait_until`, `notify_one` and `notify_all` member functions.

The executions of `notify_one` and `notify_all` are atomic. The executions of `wait`, `wait_for`, and `wait_until` are performed in three atomic parts:
1. the release of the mutex and entry into the waiting state;
2. the unblocking of the wait; and
3. the reacquisition of the lock.

The implementation behaves as if all executions of `notify_one`, `notify_all`, and each part of the `wait`, `wait_for`, and `wait_until` executions are executed in a single unspecified total order consistent with the "happens before" order.

Condition variable construction and destruction need not be synchronized.

32.6.1 Header `<condition_variable>` synopsis

```cpp
namespace std {
  class condition_variable;
  class condition_variable_any;

  void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);

  enum class cv_status { no_timeout, timeout };
}
```

32.6.2 Non-member functions

```cpp
void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);
```

1 Preconditions: `lk` is locked by the calling thread and either

1. no other thread is waiting on `cond`, or
2. `lk.mutex()` returns the same value for each of the lock arguments supplied by all concurrently waiting (via `wait`, `wait_for`, or `wait_until`) threads.

2 Effects: Transfers ownership of the lock associated with `lk` into internal storage and schedules `cond` to be notified when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed. This notification is equivalent to:

```cpp
  lk.unlock();
  cond.notify_all();
```

3 Synchronization: The implied `lk.unlock()` call is sequenced after the destruction of all objects with thread storage duration associated with the current thread.

4 [Note: The supplied lock will be held until the thread exits, and care should be taken to ensure that this does not cause deadlock due to lock ordering issues. After calling `notify_all_at_thread_exit` it is recommended that the thread should be exited as soon as possible, and that no blocking or time-consuming tasks are run on that thread. — end note]

5 [Note: It is the user’s responsibility to ensure that waiting threads do not erroneously assume that the thread has finished if they experience spurious wakeups. This typically requires that the condition being waited for is satisfied while holding the lock on `lk`, and that this lock is not released and reacquired prior to calling `notify_all_at_thread_exit`. — end note]

32.6.3 Class `condition_variable`

```cpp
namespace std {
  class condition_variable {
    public:
      condition_variable();
      ~condition_variable();

      condition_variable(const condition_variable&) = delete;
      condition_variable& operator=(const condition_variable&) = delete;
  }
```

void notify_one() noexcept;
void notify_all() noexcept;
void wait(unique_lock<mutex>& lock);

template<class Predicate>
void wait(unique_lock<mutex>& lock, Predicate pred);

template<class Clock, class Duration>
static_cv_status wait_until(unique_lock<mutex>& lock,
const chrono::time_point<Clock, Duration>& abs_time);

template<class Clock, class Duration, class Predicate>
bool wait_until(unique_lock<mutex>& lock,
const chrono::time_point<Clock, Duration>& abs_time,
Predicate pred);

template<class Rep, class Duration>
static_cv_status wait_for(unique_lock<mutex>& lock,
const chrono::duration<Rep, Duration>& rel_time);

template<class Rep, class Duration, class Predicate>
bool wait_for(unique_lock<mutex>& lock,
const chrono::duration<Rep, Duration>& rel_time,
Predicate pred);

using native_handle_type = implementation-defined; // see 32.2.3
native_handle_type native_handle(); // see 32.2.3

1 The class condition_variable is a standard-layout class (11.2).

condition_variable();

2 Throws: system_error when an exception is required (32.2.2).

3 Error conditions:

3.1 resource_unavailable_try_again — if some non-memory resource limitation prevents initialization.

~condition_variable();

4 Preconditions: There is no thread blocked on *this. [Note: That is, all threads have been notified; they could subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on *this once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of wait, wait_for, or wait_until that take a predicate. — end note]

void notify_one() noexcept;

5 Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

void notify_all() noexcept;

6 Effects: Unblocks all threads that are blocked waiting for *this.

void wait(unique_lock<mutex>& lock);

7 Preconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either

7.1 no other thread is waiting on this condition_variable object or

7.2 lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects:

8.1 Atomically calls lock.unlock() and blocks on *this.

8.2 When unblocked, calls lock.lock() (possibly blocking on the lock), then returns.

8.3 The function will unblock when signaled by a call to notify_one() or a call to notify_all(), or spuriously.

Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

Throws: Nothing.
Remarks: If the function fails to meet the postcondition, terminate() is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Predicate>
void wait(unique_lock<mutex>& lock, Predicate pred);

Preconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
  — no other thread is waiting on this condition_variable object or
  — lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects: Equivalent to:
  while (!pred())
    wait(lock);

Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

Throws: Any exception thrown by pred.

Remarks: If the function fails to meet the postcondition, terminate() is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Clock, class Duration>
cv_status wait_until(unique_lock<mutex>& lock, const chrono::time_point<Clock, Duration>& abs_time);

Preconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
  — no other thread is waiting on this condition_variable object or
  — lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects:
  — Atomically calls lock.unlock() and blocks on *this.
  — When unblocked, calls lock.lock() (possibly blocking on the lock), then returns.
  — The function will unblock when signaled by a call to notify_one(), a call to notify_all(), expiration of the absolute timeout (32.2.4) specified by abs_time, or spuriously.
  — If the function exits via an exception, lock.lock() is called prior to exiting the function.

Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

Returns: cv_status::timeout if the absolute timeout (32.2.4) specified by abs_time expired, otherwise cv_status::no_timeout.

Throws: Timeout-related exceptions (32.2.4).

Remarks: If the function fails to meet the postcondition, terminate() is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Rep, class Period>
cv_status wait_for(unique_lock<mutex>& lock, const chrono::duration<Rep, Period>& rel_time);

Preconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
  — no other thread is waiting on this condition_variable object or
  — lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects: Equivalent to:
  return wait_until(lock, chrono::steady_clock::now() + rel_time);

Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

Returns: cv_status::timeout if the relative timeout (32.2.4) specified by rel_time expired, otherwise cv_status::no_timeout.

Throws: Timeout-related exceptions (32.2.4).
Remarks: If the function fails to meet the postcondition, terminate() is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

```cpp
template<class Clock, class Duration, class Predicate>
bool wait_until(unique_lock<mutex>& lock,
const chrono::time_point<Clock, Duration>& abs_time,
Predicate pred);
```

Preconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
- no other thread is waiting on this condition_variable object or
- lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects: Equivalent to:
```cpp```
while (!pred())
  if (wait_until(lock, abs_time) == cv_status::timeout)
    return pred();
return true;
```

Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

[Note: The returned value indicates whether the predicate evaluated to true regardless of whether the timeout was triggered. — end note]

Throws: Timeout-related exceptions (32.2.4) or any exception thrown by pred.

Remarks: If the function fails to meet the postcondition, terminate() is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

```cpp
template<class Rep, class Period, class Predicate>
bool wait_for(unique_lock<mutex>& lock,
const chrono::duration<Rep, Period>& rel_time,
Predicate pred);
```

Preconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
- no other thread is waiting on this condition_variable object or
- lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects: Equivalent to:
```cpp```
return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));
```

[Note: There is no blocking if pred() is initially true, even if the timeout has already expired. — end note]

Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

[Note: The returned value indicates whether the predicate evaluates to true regardless of whether the timeout was triggered. — end note]

Throws: Timeout-related exceptions (32.2.4) or any exception thrown by pred.

Remarks: If the function fails to meet the postcondition, terminate() is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

### 32.6.4 Class condition_variable_any

A Lock type shall meet the Cpp17BasicLockable requirements (32.2.5.2). [Note: All of the standard mutex types meet this requirement. If a Lock type other than one of the standard mutex types or a unique_lock wrapper for a standard mutex type is used with condition_variable_any, the user should ensure that any necessary synchronization is in place with respect to the predicate associated with the condition_variable_any instance. — end note]

```cpp```
namespace std {
  class condition_variable_any {
    public:
      condition_variable_any();
      ~condition_variable_any();

      condition_variable_any(const condition_variable_any&) = delete;
      condition_variable_any& operator=(const condition_variable_any&) = delete;
  }
}
```

§ 32.6.4
void notify_one() noexcept;
void notify_all() noexcept;

// 32.6.4.1, noninterruptible waits
template<class Lock>
void wait(Lock& lock);
template<class Lock, class Predicate>
void wait(Lock& lock, Predicate pred);

template<class Lock, class Clock, class Duration>
  cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);
template<class Lock, class Clock, class Duration, class Predicate>
  bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);
template<class Lock, class Rep, class Period>
  cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
template<class Lock, class Rep, class Period, class Predicate>
  bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);

// 32.6.4.2, interruptible waits

template<class Lock, class Predicate>
  bool wait(Lock& lock, stop_token stoken, Predicate pred);
template<class Lock, class Clock, class Duration, class Predicate>
  bool wait_until(Lock& lock, stop_token stoken, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);
template<class Lock, class Rep, class Period, class Predicate>
  bool wait_for(Lock& lock, stop_token stoken, const chrono::duration<Rep, Period>& rel_time, Predicate pred);

condition_variable_any();

Throws: bad_alloc or system_error when an exception is required (32.2.2).

Error conditions:
(1) — resource_unavailable_try_again — if some non-memory resource limitation prevents initialization.
(2) — operation_not_permitted — if the thread does not have the privilege to perform the operation.

Preconditions: There is no thread blocked on *this. [Note: That is, all threads have been notified; they could
subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required
all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before
destruction. The user should take care to ensure that no threads wait on *this once the destructor has been
started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of
wait, wait_for, or wait_until that take a predicate. — end note]

void notify_one() noexcept;

Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

void notify_all() noexcept;

Effects: Unblocks all threads that are blocked waiting for *this.

32.6.4.1 Noninterruptible waits

template<class Lock>
void wait(Lock& lock);

Effects:
(1) — Atomically calls lock.unlock() and blocks on *this.
(2) — When unblocked, calls lock.lock() (possibly blocking on the lock) and returns.
The function will unblock when signaled by a call to `notify_one()`, a call to `notify_all()`, or spuriously.

Postconditions: `lock` is locked by the calling thread.

Throws: Nothing.

Remarks: If the function fails to meet the postcondition, `terminate()` is called ([14.6.1]). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Lock, class Predicate>
void wait(Lock& lock, Predicate pred);

Effects: Equivalent to:
while (!pred())
    wait(lock);

template<class Lock, class Clock, class Duration>
cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);

Effects:
- Atomically calls `lock.unlock()` and blocks on *this.
- When unblocked, calls `lock.lock()` (possibly blocking on the lock) and returns.
- The function will unblock when signaled by a call to `notify_one()`, a call to `notify_all()`, expiration of the absolute timeout ([32.2.4]) specified by `abs_time`, or spuriously.
- If the function exits via an exception, `lock.lock()` is called prior to exiting the function.

Postconditions: `lock` is locked by the calling thread.

Returns: `cv_status::timeout` if the absolute timeout ([32.2.4]) specified by `abs_time` expired, otherwise `cv_status::no_timeout`.

Throws: Timeout-related exceptions ([32.2.4]).

Remarks: If the function fails to meet the postcondition, `terminate()` is called ([14.6.1]). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Lock, class Rep, class Period>
cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);

Effects: Equivalent to:
return wait_until(lock, chrono::steady_clock::now() + rel_time);

Postconditions: `lock` is locked by the calling thread.

Returns: `cv_status::timeout` if the relative timeout ([32.2.4]) specified by `rel_time` expired, otherwise `cv_status::no_timeout`.

Throws: Timeout-related exceptions ([32.2.4]).

Remarks: If the function fails to meet the postcondition, `terminate()` is called ([14.6.1]). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Lock, class Clock, class Duration, class Predicate>
bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);

Effects: Equivalent to:
while (!pred())
    if (wait_until(lock, abs_time) == cv_status::timeout)
        return pred();
    return true;

[Note: There is no blocking if `pred()` is initially true, or if the timeout has already expired. — end note]

[Note: The returned value indicates whether the predicate evaluates to `true` regardless of whether the timeout was triggered. — end note]
bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);

Effects: Equivalent to:

\[
\text{return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));}
\]

32.6.4.2 Interruptible waits

The following wait functions will be notified when there is a stop request on the passed stop_token. In that case the functions return immediately, returning false if the predicate evaluates to false.

template<class Lock, class Predicate>
bool wait(Lock& lock, stop_token stoken, Predicate pred);

Effects: Registers for the duration of this call *this to get notified on a stop request on stoken during this call and then equivalent to:

\[
\begin{align*}
\text{while (!stoken.stop_requested())} & \quad \text{if (pred())} \\
\text{&} \quad \text{return true;} \\
\text{&} \quad \text{wait(lock);} \\
\text{&} \quad \text{return pred();}
\end{align*}
\]

[Note: The returned value indicates whether the predicate evaluated to true regardless of whether there was a stop request. — end note]

Postconditions: lock is locked by the calling thread.

Throws: Any exception thrown by pred.

Remarks: If the function fails to meet the postcondition, terminate is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Lock, class Clock, class Duration, class Predicate>
bool wait_until(Lock& lock, stop_token stoken, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);

Effects: Registers for the duration of this call *this to get notified on a stop request on stoken during this call and then equivalent to:

\[
\begin{align*}
\text{while (!stoken.stop_requested())} & \quad \text{if (pred())} \\
\text{&} \quad \text{return true;} \\
\text{&} \quad \text{if (wait_until(lock, abs_time) == cv_status::timeout)} \\
\text{&} \quad \text{return pred();}
\end{align*}
\]

[Note: There is no blocking if pred() is initially true, stoken.stop_requested() was already true or the timeout has already expired. — end note]

[Note: The returned value indicates whether the predicate evaluated to true regardless of whether the timeout was triggered or a stop request was made. — end note]

Postconditions: lock is locked by the calling thread.

Throws: Timeout-related exceptions (32.2.4), or any exception thrown by pred.

Remarks: If the function fails to meet the postcondition, terminate is called (14.6.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

template<class Lock, class Rep, class Period, class Predicate>
bool wait_for(Lock& lock, stop_token stoken, const chrono::duration<Rep, Period>& rel_time, Predicate pred);

Effects: Equivalent to:

\[
\text{return wait_until(lock, std::move(stoken), chrono::steady_clock::now() + rel_time, std::move(pred));}
\]
32.7 Semaphore

Semaphores are lightweight synchronization primitives used to constrain concurrent access to a shared resource. They are widely used to implement other synchronization primitives and, whenever both are applicable, can be more efficient than condition variables.

A counting semaphore is a semaphore object that models a non-negative resource count. A binary semaphore is a semaphore object that has only two states. A binary semaphore should be more efficient than the default implementation of a counting semaphore with a unit resource count.

32.7.1 Header <semaphore> synopsis

```
namespace std {
    template<ptrdiff_t least_max_value = implementation-defined>
    class counting_semaphore;

    using binary_semaphore = counting_semaphore<1>;
}
```

32.7.2 Class template counting_semaphore

```
namespace std {
    template<ptrdiff_t least_max_value = implementation-defined>
    class counting_semaphore {
public:
    static constexpr ptrdiff_t max() noexcept;
    constexpr explicit counting_semaphore(ptrdiff_t desired);
    ~counting_semaphore();
    counting_semaphore(const counting_semaphore&) = delete;
    counting_semaphore& operator=(const counting_semaphore&) = delete;
    void release(ptrdiff_t update = 1);
    void acquire();
    bool try_acquire() noexcept;
    template<class Rep, class Period>
    bool try_acquire_for(const chrono::duration<Rep, Period>& rel_time);
    template<class Clock, class Duration>
    bool try_acquire_until(const chrono::time_point<Clock, Duration>& abs_time);

private:
    ptrdiff_t counter;            // exposition only
};
```

Class template counting_semaphore maintains an internal counter that is initialized when the semaphore is created. The counter is decremented when a thread acquires the semaphore, and is incremented when a thread releases the semaphore. If a thread tries to acquire the semaphore when the counter is zero, the thread will block until another thread increments the counter by releasing the semaphore.

least_max_value shall be non-negative; otherwise the program is ill-formed.

Concurrent invocations of the member functions of counting_semaphore, other than its destructor, do not introduce data races.

```
static constexpr ptrdiff_t max() noexcept;
```

**Returns:** The maximum value of counter. This value is greater than or equal to least_max_value.

```
constexpr explicit counting_semaphore(ptrdiff_t desired);
```

**Preconditions:** desired \( \geq 0 \) is true, and desired \( \leq \) max() is true.

**Effects:** Initializes counter with desired.

**Throws:** Nothing.
void release(ptrdiff_t update = 1);

Preconditions: update >= 0 is true, and update <= max() - counter is true.

Effects: Atomically execute counter += update. Then, unblocks any threads that are waiting for counter to be greater than zero.

Synchronization: Strongly happens before invocations of try_acquire that observe the result of the effects.

Throws: system_error when an exception is required (32.2.2).

Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

bool try_acquire() noexcept;

Effects: Attempts to atomically decrement counter if it is positive, without blocking. If counter is not decremented, there is no effect and try_acquire immediately returns. An implementation may fail to decrement counter even if it is positive. [Note: This spurious failure is normally uncommon, but allows interesting implementations based on a simple compare and exchange (Clause 31). – end note] An implementation should ensure that try_acquire does not consistently return false in the absence of contending semaphore operations.

Returns: true if counter was decremented, otherwise false.

void acquire();

Effects: Repeatedly performs the following steps, in order:
— Evaluates try_acquire. If the result is true, returns.
— Blocks on *this until counter is greater than zero.

Throws: system_error when an exception is required (32.2.2).

Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

template<class Rep, class Period>
bool try_acquire_for(const chrono::duration<Rep, Period>& rel_time);
template<class Clock, class Duration>
bool try_acquire_until(const chrono::time_point<Clock, Duration>& abs_time);

Effects: Repeatedly performs the following steps, in order:
— Evaluates try_acquire(). If the result is true, returns true.
— Blocks on *this until counter is greater than zero or until the timeout expires. If it is unblocked by the timeout expiring, returns false.

The timeout expires (32.2.4) when the current time is after abs_time (for try_acquire_until) or when at least rel_time has passed from the start of the function (for try_acquire_for).

Throws: Timeout-related exceptions (32.2.4), or system_error when a non-timeout-related exception is required (32.2.2).

Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

32.8 Coordination types [thread.coord]

This subclause describes various concepts related to thread coordination, and defines the coordination types latch and barrier. These types facilitate concurrent computation performed by a number of threads.

32.8.1 Latches [thread.latch]

A latch is a thread coordination mechanism that allows any number of threads to block until an expected number of threads arrive at the latch (via the count_down function). The expected count is set when the latch is created. An individual latch is a single-use object; once the expected count has been reached, the latch cannot be reused.

32.8.1.1 Header <latch> synopsis [latch.syn]

namespace std {
    class latch;
};
namespace std {
  class latch {
    public:
      static constexpr ptrdiff_t max() noexcept;
      constexpr explicit latch(ptrdiff_t expected);
      ~latch();
      latch(const latch&) = delete;
      latch& operator=(const latch&) = delete;
      void count_down(ptrdiff_t update = 1);
      bool try_wait() const noexcept;
      void wait() const;
      void arrive_and_wait(ptrdiff_t update = 1);

    private:
      ptdiff_t counter;  // exposition only
  };
}

A latch maintains an internal counter that is initialized when the latch is created. Threads can block on the latch object, waiting for counter to be decremented to zero.

Concurrent invocations of the member functions of latch, other than its destructor, do not introduce data races.

static constexpr ptdiff_t max() noexcept;
Returns: The maximum value of counter that the implementation supports.

constexpr explicit latch(ptrdiff_t expected);
Preconditions: expected >= 0 is true and expected <= max() is true.
Effects: Initializes counter with expected.
Throws: Nothing.

void count_down(ptrdiff_t update = 1);
Preconditions: update >= 0 is true, and update <= counter is true.
Effects: Atomically decrements counter by update. If counter is equal to zero, unblocks all threads blocked on *this.
Synchronization: Strongly happens before the returns from all calls that are unblocked.
Throws: system_error when an exception is required (32.2.2).
Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

bool try_wait() const noexcept;
Returns: With very low probability false. Otherwise counter == 0.

void wait() const;
Effects: If counter equals zero, returns immediately. Otherwise, blocks on *this until a call to count_down that decrements counter to zero.
Throws: system_error when an exception is required (32.2.2).
Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

void arrive_and_wait(ptrdiff_t update = 1);
Effects: Equivalent to:
  count_down(update);
  wait();
A barrier is a thread coordination mechanism whose lifetime consists of a sequence of barrier phases, where each phase allows at most an expected number of threads to block until the expected number of threads arrive at the barrier. [Note: A barrier is useful for managing repeated tasks that are handled by multiple threads. — end note]

### 32.8.2.1 Header <barrier> synopsis
```cpp
namespace std {
    template<class CompletionFunction = see below>
    class barrier;
}
```

### 32.8.2.2 Class template barrier
```cpp
namespace std {
    template<class CompletionFunction = see below>
    class barrier {
    public:
        using arrival_token = see below;
        static constexpr ptrdiff_t max() noexcept;
        constexpr explicit barrier(ptrdiff_t expected,
                            CompletionFunction f = CompletionFunction());
        ~barrier();
        barrier(const barrier&) = delete;
        barrier& operator=(const barrier&) = delete;

        [[nodiscard]] arrival_token arrive(ptrdiff_t update = 1);
        void wait(arrival_token&& arrival) const;
        void arrive_and_wait();
        void arrive_and_drop();

    private:
        CompletionFunction completion; // exposition only
    };
```

1 Each barrier phase consists of the following steps:
   1. The expected count is decremented by each call to arrive or arrive_and_drop.
   2. When the expected count reaches zero, the phase completion step is run. For the specialization with the default value of the CompletionFunction template parameter, the completion step is run as part of the call to arrive or arrive_and_drop that caused the expected count to reach zero. For other specializations, the completion step is run on one of the threads that arrived at the barrier during the phase.
   3. When the completion step finishes, the expected count is reset to what was specified by the expected argument to the constructor, possibly adjusted by calls to arrive_and_drop, and the next phase starts.

2 Each phase defines a phase synchronization point. Threads that arrive at the barrier during the phase can block on the phase synchronization point by calling wait, and will remain blocked until the phase completion step is run.

3 The phase completion step that is executed at the end of each phase has the following effects:
   1. Invokes the completion function, equivalent to completion().
   2. Unblocks all threads that are blocked on the phase synchronization point.

The end of the completion step strongly happens before the returns from all calls that were unblocked by the completion step. For specializations that do not have the default value of the CompletionFunction template parameter, the behavior is undefined if any of the barrier object’s member functions other than wait are called while the completion step is in progress.

4 Concurrent invocations of the member functions of barrier, other than its destructor, do not introduce data races. The member functions arrive and arrive_and_drop execute atomically.
CompletionFunction shall meet the Cpp17MoveConstructible (Table 28) and Cpp17Destructible (Table 32) requirements. is_nothrow_invocable_v<CompletionFunction&> shall be true.

The default value of the CompletionFunction template parameter is an unspecified type, such that, in addition to satisfying the requirements of CompletionFunction, it meets the Cpp17DefaultConstructible requirements (Table 27) and completion() has no effects.

barrier::arrival_token is an unspecified type, such that it meets the Cpp17MoveConstructible (Table 28), Cpp17MoveAssignable (Table 30), and Cpp17Destructible (Table 32) requirements.

static constexpr ptrdiff_t max() noexcept;

Returns: The maximum expected count that the implementation supports.

constexpr explicit barrier(ptrdiff_t expected, 
CompletionFunction f = CompletionFunction());

Preconditions: expected >= 0 is true and expected <= max() is true.

Effects: Sets both the initial expected count for each barrier phase and the current expected count for the first phase to expected. Initializes completion with std::move(f). Starts the first phase. [Note: If expected is 0 this object can only be destroyed. — end note]

Throws: Any exception thrown by CompletionFunction’s move constructor.

[[nodiscard]] arrival_token arrive(ptrdiff_t update = 1);

Preconditions: update > 0 is true, and update is less than or equal to the expected count for the current barrier phase.

Effects: Constructs an object of type arrival_token that is associated with the phase synchronization point for the current phase. Then, decrements the expected count by update.

Synchronization: The call to arrive strongly happens before the start of the phase completion step for the current phase.

Returns: The constructed arrival_token object.

Throws: system_error when an exception is required (32.2.2).

Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

[Note: This call can cause the completion step for the current phase to start. — end note]

void wait(arrival_token&& arrival) const;

Preconditions: arrival is associated with the phase synchronization point for the current phase or the immediately preceding phase of the same barrier object.

Effects: Blocks at the synchronization point associated with std::move(arrival) until the phase completion step of the synchronization point’s phase is run. [Note: If arrival is associated with the synchronization point for a previous phase, the call returns immediately. — end note]

Throws: system_error when an exception is required (32.2.2).

Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

void arrive_and_wait();

Effects: Equivalent to: wait(arrive()).

void arrive_and_drop();

Preconditions: The expected count for the current barrier phase is greater than zero.

Effects: Decrement the initial expected count for all subsequent phases by one. Then decrements the expected count for the current phase by one.

Synchronization: The call to arrive_and_drop strongly happens before the start of the phase completion step for the current phase.

 Throws: system_error when an exception is required (32.2.2).

Error conditions: Any of the error conditions allowed for mutex types (32.5.3.2).

[Note: This call can cause the completion step for the current phase to start. — end note]
32.9 Futures

32.9.1 Overview

32.9 describes components that a C++ program can use to retrieve in one thread the result (value or exception) from a function that has run in the same thread or another thread. [Note: These components are not restricted to multi-threaded programs but can be useful in single-threaded programs as well. — end note]

32.9.2 Header <future> synopsis

namespace std {
    enum class future_errc {
        broken_promise = implementation-defined,
        future_already_retrieved = implementation-defined,
        promise_already_satisfied = implementation-defined,
        no_state = implementation-defined
    };

    enum class launch : unspecified {
        async = unspecified,
        deferred = unspecified,
        implementation-defined
    };

    enum class future_status {
        ready,
        timeout,
        deferred
    };

    template<> struct is_error_code_enum<future_errc> : public true_type { }; 

    error_code make_error_code(future_errc e) noexcept;
    error_condition make_error_condition(future_errc e) noexcept;

    const error_category& future_category() noexcept;

    class future_error;

    template<class R> class promise;
    template<class R> class promise<R&>;
    template<> class promise<void>;

    template<class R>
    void swap(promise<R>& x, promise<R>& y) noexcept;

    template<class R, class Alloc>
    struct uses_allocator<promise<R>, Alloc>;

    template<class R> class future;
    template<class R> class future<R&>;
    template<> class future<void>;

    template<class R> class shared_future;
    template<class R> class shared_future<R&>;
    template<> class shared_future<void>;

    template<class> class packaged_task;   // not defined
    template<class R, class... ArgTypes>
    class packaged_task<R(ArgTypes...)>;

    template<class R, class... ArgTypes>
    void swap(packaged_task<R(ArgTypes...)>&, packaged_task<R(ArgTypes...)>&) noexcept;

    template<class F, class... Args>
    [[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
        async(F&& f, Args&&... args);
}
template<class F, class... Args>
    [[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
    async(launch policy, F&& f, Args&&... args);

The enum type `launch` is a bitmask type (16.4.2.2.4) with elements `launch::async` and `launch::deferred`. [Note: Implementations can provide bitmasks to specify restrictions on task interaction by functions launched by `async()` applicable to a corresponding subset of available launch policies. Implementations can extend the behavior of the first overload of `async()` by adding their extensions to the launch policy under the “as if” rule. — end note]

The enum values of `future_errc` are distinct and not zero.

### 32.9.3 Error handling

```cpp
const error_category& future_category() noexcept;
```

Returns: A reference to an object of a type derived from class `error_category`.

```cpp
error_code make_error_code(future_errc e) noexcept;
```

Returns: `error_code(static_cast<int>(e), future_category())`.

```cpp
error_condition make_error_condition(future_errc e) noexcept;
```

Returns: `error_condition(static_cast<int>(e), future_category())`.

### 32.9.4 Class future_error

```cpp
namespace std {
    class future_error : public logic_error {
        explicit future_error(future_errc e);
        const error_code& code() const noexcept;
        const char* what() const noexcept;
    private:
        error_code ec_; // exposition only
    };
}
```

Explicit `future_error(future_errc e)`;

Effects: Initializes `ec_` with `make_error_code(e)`.

```cpp
const error_code& code() const noexcept;
```

Returns: `ec_`.

```cpp
const char* what() const noexcept;
```

Returns: An NTPS incorporating `code().message()`.

### 32.9.5 Shared state

Many of the classes introduced in subclause 32.9 use some state to communicate results. This *shared state* consists of some state information and some (possibly not yet evaluated) *result*, which can be a (possibly void) value or an exception. [Note: Futures, promises, and tasks defined in this Clause reference such shared state. — end note]

[Note: The result can be any kind of object including a function to compute that result, as used by `async` when policy is `launch::deferred`. — end note]

An *asynchronous return object* is an object that reads results from a shared state. A *waiting function* of an asynchronous return object is one that potentially blocks to wait for the shared state to be made ready. If a waiting function can return before the state is made ready because of a timeout (32.2.5), then it is a *timed waiting function*, otherwise it is a *non-timed waiting function*.

[Note: Such as promises or tasks. — end note] The means of
setting the result of a shared state is specified in the description of those classes and functions that create such a state object.

5 When an asynchronous return object or an asynchronous provider is said to release its shared state, it means:
   (5.1) if the return object or provider holds the last reference to its shared state, the shared state is destroyed; and
   (5.2) the return object or provider gives up its reference to its shared state; and
   (5.3) these actions will not block for the shared state to become ready, except that it may block if all of the following are true: the shared state was created by a call to `std::async`, the shared state is not yet ready, and this was the last reference to the shared state.

6 When an asynchronous provider is said to make its shared state ready, it means:
   (6.1) first, the provider marks its shared state as ready; and
   (6.2) second, the provider unblocks any execution agents waiting for its shared state to become ready.

7 When an asynchronous provider is said to abandon its shared state, it means:
   (7.1) first, if that state is not ready, the provider
       (7.1.1) stores an exception object of type `future_error` with an error condition of `broken_promise` within its shared state; and then
       (7.1.2) makes its shared state ready;
   (7.2) second, the provider releases its shared state.

8 A shared state is ready only if it holds a value or an exception ready for retrieval. Waiting for a shared state to become ready may invoke code to compute the result on the waiting thread if so specified in the description of the class or function that creates the state object.

9 Calls to functions that successfully set the stored result of a shared state synchronize with (6.9.2) calls to functions successfully detecting the ready state resulting from that setting. The storage of the result (whether normal or exceptional) into the shared state synchronizes with (6.9.2) the successful return from a call to a waiting function on the shared state.

10 Some functions (e.g., `promise::set_value_at_thread_exit`) delay making the shared state ready until the calling thread exits. The destruction of each of that thread's objects with thread storage duration (6.7.5.2) is sequenced before making that shared state ready.

11 Access to the result of the same shared state may conflict (6.9.2). [Note: This explicitly specifies that the result of the shared state is visible in the objects that reference this state in the sense of data race avoidance (16.5.5.10). For example, concurrent accesses through references returned by `shared_future::get()` (32.9.8) must either use read-only operations or provide additional synchronization. — end note]

### 32.9.6 Class template promise

```cpp
namespace std {
    template<class R>
    class promise {
        public:
            promise();
            template<class Allocator>
                promise(allocator_arg_t, const Allocator& a);
            promise(promise&& rhs) noexcept;
            promise(const promise&) = delete;
            ~promise();

            // assignment
            promise& operator=(promise&& rhs) noexcept;
            promise& operator=(const promise&) = delete;
            void swap(promise& other) noexcept;

            // retrieving the result
            future<R> get_future();

            // setting the result
            void set_value(see below);
            void set_exception(exception_ptr p);
}
```
// setting the result with deferred notification
void set_value_at_thread_exit(see below);
void set_exception_at_thread_exit(exception_ptr p);
};

template<class R>
void swap(promise<R>& x, promise<R>& y) noexcept;

template<class R, class Alloc>
struct uses_allocator<promise<R>, Alloc> {
    true_type {};

    Preconditions: Alloc meets the Cpp17Allocator requirements (Table 36).

    promise();
    template<class Allocator>
    promise(allocator_arg_t, const Allocator& a);

    Effects: Creates a shared state. The second constructor uses the allocator a to allocate memory for the shared state.

    promise(promise&& rhs) noexcept;

    Effects: Transfers ownership of the shared state of rhs (if any) to the newly-constructed object.

    Postconditions: rhs has no shared state.

    ~promise();

    Effects: Abandons any shared state (32.9.5).

    promise& operator=(promise&& rhs) noexcept;

    Effects: Abandons any shared state (32.9.5) and then as if promise(std::move(rhs)).swap(*this).

    Returns: *this.

    void swap(promise& other) noexcept;

    Effects: Exchanges the shared state of *this and other.

    Postconditions: *this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

    future<R> get_future();

    Returns: A future<R> object with the same shared state as *this.

    Synchronization: Calls to this function do not introduce data races (6.9.2) with calls to set_value, set_exception, set_value_at_thread_exit, or set_exception_at_thread_exit. [Note: Such calls need not synchronize with each other. — end note]

    Throws: future_error if *this has no shared state or if get_future has already been called on a promise with the same shared state as *this.

    Error conditions:
    — future_already_retrieved if get_future has already been called on a promise with the same shared state as *this.
    — no_state if *this has no shared state.
© ISO/IEC

```cpp
void promise::set_value(const R& r);
void promise::set_value(R&& r);
void promise<R&>::set_value(R& r);
void promise<void>::set_value();
```

**Effects:** Atomically stores the value r in the shared state and makes that state ready (32.9.5).

**Throws:**
- `future_error` if its shared state already has a stored value or exception, or
- for the first version, any exception thrown by the constructor selected to copy an object of R, or
- for the second version, any exception thrown by the constructor selected to move an object of R.

**Error conditions:**
- `promise_already_satisfied` if its shared state already has a stored value or exception.
- `no_state` if *this has no shared state.

```cpp
void set_exception(exception_ptr p);
```

**Preconditions:** p is not null.

**Effects:** Atomically stores the exception pointer p in the shared state and makes that state ready (32.9.5).

**Throws:** `future_error` if its shared state already has a stored value or exception.

**Error conditions:**
- `promise_already_satisfied` if its shared state already has a stored value or exception.
- `no_state` if *this has no shared state.

```cpp
void promise::set_value_at_thread_exit(const R& r);
void promise::set_value_at_thread_exit(R&& r);
void promise<R&>::set_value_at_thread_exit(R& r);
void promise<void>::set_value_at_thread_exit();
```

**Effects:** Stores the value r in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

**Throws:**
- `future_error` if its shared state already has a stored value or exception, or
- for the first version, any exception thrown by the constructor selected to copy an object of R, or
- for the second version, any exception thrown by the constructor selected to move an object of R.

**Error conditions:**
- `promise_already_satisfied` if its shared state already has a stored value or exception.
- `no_state` if *this has no shared state.

```cpp
void set_exception_at_thread_exit(exception_ptr p);
```

**Preconditions:** p is not null.

**Effects:** Stores the exception pointer p in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

**Throws:** `future_error` if an error condition occurs.

**Error conditions:**
- `promise_already_satisfied` if its shared state already has a stored value or exception.
- `no_state` if *this has no shared state.

```cpp
template<class R>
void swap(promise<R>& x, promise<R>& y) noexcept;
```

**Effects:** As if by x.swap(y).
### 32.9.7 Class template future [futures.unique.future]

1. The class template `future` defines a type for asynchronous return objects which do not share their shared state with other asynchronous return objects. A default-constructed `future` object has no shared state. A `future` object with shared state can be created by functions on asynchronous providers (32.9.5) or by the move constructor and shares its shared state with the original asynchronous provider. The result (value or exception) of a `future` object can be set by calling a respective function on an object that shares the same shared state.

2. [Note: Member functions of `future` do not synchronize with themselves or with member functions of `shared_future`. — end note]

3. The effect of calling any member function other than the destructor, the move-assignment operator, `share`, or `valid` on a `future` object for which `valid()` == `false` is undefined. [Note: It is valid to move from a future object for which `valid()` == `false`. — end note] [Note: Implementations should detect this case and throw an object of type `future_error` with an error condition of `future_errc::no_state`. — end note]

```cpp
namespace std {
    template<class R>
    class future {
    public:
        future() noexcept;
        future(future&&) noexcept;
        future(const future&) = delete;
        ~future();
        future& operator=(const future&) = delete;
        future& operator=(future&&) noexcept;
        shared_future<R> share() noexcept;

        // retrieving the value
        see below get();

        // functions to check state
        bool valid() const noexcept;
        void wait() const;
        template<class Rep, class Period>
        future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
        template<class Clock, class Duration>
        future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
    };
}
```

4. The implementation provides the template `future` and two specializations, `future<R&>` and `future<void>`. These differ only in the return type and return value of the member function `get`, as set out in its description, below.

- `future()` noexcept;

  Effects: The object does not refer to a shared state.

  Postconditions: `valid()` == `false`.

- `future(future&& rhs)` noexcept;

  Effects: Move constructs a `future` object that refers to the shared state that was originally referred to by `rhs` (if any).

  Postconditions:

  (8.1) `valid()` returns the same value as `rhs.valid()` prior to the constructor invocation.

  (8.2) `rhs.valid()` == `false`.

- `~future();`

  Effects:

  (9.1) Releases any shared state (32.9.5);

  (9.2) destroys `*this`.

§ 32.9.7
future& operator=(future&& rhs) noexcept;

Effects:
— Releases any shared state (32.9.5).
— move assigns the contents of rhs to *this.

Postconditions:
— valid() returns the same value as rhs.valid() prior to the assignment.
— rhs.valid() == false.

shared_future<R> share() noexcept;

Postconditions: valid() == false.

Returns: shared_future<R>(std::move(*this)).

R future::get();
R& future<R&>::get();
void future<void>::get();

[Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function get. — end note]

Effects:
— waits until the shared state is ready, then retrieves the value stored in the shared state;
— releases any shared state (32.9.5).

Postconditions: valid() == false.

Returns:
— future::get() returns the value v stored in the object’s shared state as std::move(v).
— future<R&>::get() returns the reference stored as value in the object’s shared state.
— future<void>::get() returns nothing.

Throws: The stored exception, if an exception was stored in the shared state.

bool valid() const noexcept;

Returns: true only if *this refers to a shared state.

void wait() const;

Effects: Blocks until the shared state is ready.

template<class Rep, class Period>
future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;

Effects: None if the shared state contains a deferred function (32.9.9), otherwise blocks until the shared state is ready or until the relative timeout (32.2.4) specified by rel_time has expired.

Returns:
— future_status::deferred if the shared state contains a deferred function.
— future_status::ready if the shared state is ready.
— future_status::timeout if the function is returning because the relative timeout (32.2.4) specified by rel_time has expired.

Throws: timeout-related exceptions (32.2.4).

template<class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;

Effects: None if the shared state contains a deferred function (32.9.9), otherwise blocks until the shared state is ready or until the absolute timeout (32.2.4) specified by abs_time has expired.

Returns:
— future_status::deferred if the shared state contains a deferred function.
future_status::ready if the shared state is ready.

— future_status::timeout if the function is returning because the absolute timeout (32.2.4) specified by abs_time has expired.

26 Throws: timeout-related exceptions (32.2.4).

32.9.8 Class template shared_future [futures.shared.future]

The class template shared_future defines a type for asynchronous return objects which may share their shared state with other asynchronous return objects. A default-constructed shared_future object has no shared state. A shared_future object with shared state can be created by conversion from a future object and shares its shared state with the original asynchronous provider (32.9.5) of the shared state. The result (value or exception) of a shared_future object can be set by calling a respective function on an object that shares the same shared state.

[Note: Member functions of shared_future do not synchronize with themselves, but they synchronize with the shared state. — end note]

The effect of calling any member function other than the destructor, the move-assignment operator, the copy-assignment operator, or valid() on a shared_future object for which valid() == false is undefined. [Note: It is valid to copy or move from a shared_future object for which valid() is false. — end note] [Note: Implementations should detect this case and throw an object of type future_error with an error condition of future_errc::no_state. — end note]

namespace std {
    template<class R>
    class shared_future {
    public:
        shared_future() noexcept;
        shared_future(const shared_future& rhs) noexcept;
        shared_future(future<R>&& rhs) noexcept;
        shared_future(shared_future&& rhs) noexcept;
        ~shared_future();
        shared_future& operator=(const shared_future& rhs) noexcept;
        shared_future& operator=(shared_future&& rhs) noexcept;
        // retrieving the value
        see below get() const;
        // functions to check state
        bool valid() const noexcept;
        void wait() const;
        template<class Rep, class Period>
            future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
        template<class Clock, class Duration>
            future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
    };
}

4 The implementation provides the template shared_future and two specializations, shared_future<R&> and shared_future<void>. These differ only in the return type and return value of the member function get, as set out in its description, below.

shared_future() noexcept;

Effects: The object does not refer to a shared state.

Postconditions: valid() == false.

shared_future(const shared_future& rhs) noexcept;

Effects: The object refers to the same shared state as rhs (if any).

Postconditions: valid() returns the same value as rhs.valid().

shared_future(future<R>&& rhs) noexcept;
shared_future(shared_future&& rhs) noexcept;

Effects: Move constructs a shared_future object that refers to the shared state that was originally referred to by rhs (if any).

Postconditions:
(10.1) valid() returns the same value as rhs.valid() returned prior to the constructor invocation.
(10.2) rhs.valid() == false.

~shared_future();

Effects:
(11.1) Releases any shared state (32.9.5);
(11.2) destroys *this.

shared_future& operator=(shared_future&& rhs) noexcept;

Effects:
(12.1) Releases any shared state (32.9.5);
(12.2) move assigns the contents of rhs to *this.

Postconditions:
(13.1) valid() returns the same value as rhs.valid() returned prior to the assignment.
(13.2) rhs.valid() == false.

shared_future& operator=(const shared_future& rhs) noexcept;

Effects:
(14.1) Releases any shared state (32.9.5);
(14.2) assigns the contents of rhs to *this. [Note: As a result, *this refers to the same shared state as rhs (if any). — end note]

Postconditions: valid() == rhs.valid().

const R& shared_future::get() const;
R& shared_future<R&>::get() const;
void shared_future<void>::get() const;

[Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function get. — end note]

[Note: Access to a value object stored in the shared state is unsynchronized, so programmers should apply only those operations on R that do not introduce a data race (6.9.2). — end note]

Effects: wait()s until the shared state is ready, then retrieves the value stored in the shared state.

Returns:
(19.1) shared_future::get() returns a const reference to the value stored in the object’s shared state. [Note: Access through that reference after the shared state has been destroyed produces undefined behavior; this can be avoided by not storing the reference in any storage with a greater lifetime than the shared_future object that returned the reference. — end note]
(19.2) shared_future<R&>::get() returns the reference stored as value in the object’s shared state.
(19.3) shared_future<void>::get() returns nothing.

Throws: The stored exception, if an exception was stored in the shared state.

bool valid() const noexcept;

Returns: true only if *this refers to a shared state.

void wait() const;

Effects: Blocks until the shared state is ready.
template<class Rep, class Period>
future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;

Effects: None if the shared state contains a deferred function (32.9.9), otherwise blocks until the shared state is ready or until the relative timeout (32.2.4) specified by rel_time has expired.

Returns:
(24.1) — future_status::deferred if the shared state contains a deferred function.
(24.2) — future_status::ready if the shared state is ready.
(24.3) — future_status::timeout if the function is returning because the relative timeout (32.2.4) specified by rel_time has expired.

Throws: timeout-related exceptions (32.2.4).

template<class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;

Effects: None if the shared state contains a deferred function (32.9.9), otherwise blocks until the shared state is ready or until the absolute timeout (32.2.4) specified by abs_time has expired.

Returns:
(27.1) — future_status::deferred if the shared state contains a deferred function.
(27.2) — future_status::ready if the shared state is ready.
(27.3) — future_status::timeout if the function is returning because the absolute timeout (32.2.4) specified by abs_time has expired.

Throws: timeout-related exceptions (32.2.4).

32.9.9 Function template async

The function template async provides a mechanism to launch a function potentially in a new thread and provides the result of the function in a future object with which it shares a shared state.

template<class F, class... Args>
[[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
async(F&& f, Args&&... args);

template<class F, class... Args>
[[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
async(launch policy, F&& f, Args&&... args);

Mandates: The following are all true:
(2.1) — is_constructible_v<decay_t<F>, F>,
(2.2) — (is_constructible_v<decay_t<Args>, Args> &&...),
(2.3) — is_move_constructible_v<decay_t<F>>,
(2.4) — (is_move_constructible_v<decay_t<Args>> &&...), and
(2.5) — is_invocable_v<decay_t<F>, decay_t<Args>...>.

Preconditions: decay_t<F> and each type in decay_t<Args> meet the Cpp17MoveConstructible requirements.

Effects: The first function behaves the same as a call to the second function with a policy argument of launch::async | launch::deferred and the same arguments for F and Args. The second function creates a shared state that is associated with the returned future object. The further behavior of the second function depends on the policy argument as follows (if more than one of these conditions applies, the implementation may choose any of the corresponding policies):
(4.1) — If launch::async is set in policy, calls invoke(decay-copy(std::forward<F>(f)), decay-copy(std::forward<Args>(args))) as if in a new thread of execution represented by a thread object with the calls to decay-copy being evaluated in the thread that called async. Any return value is stored as the result in the shared state. Any exception propagated from the execution of invoke(decay-copy(std::forward<F>(f)), decay-copy(std::forward<Args>(args)))... is stored as the exceptional result in the shared state. The thread object is stored in the shared state and affects the behavior of any asynchronous return objects that reference that state.
If `launch::deferred` is set in policy, stores `decay-copy(std::forward<F>(f))` and `decay-copy(std::forward<Args>(args))` in the shared state. These copies of `f` and `args` constitute a deferred function. Invocation of the deferred function evaluates `invoke(std::move(g), std::move(xyz))` where `g` is the stored value of `decay-copy(std::forward<F>(f))` and `xyz` is the stored copy of `decay-copy(std::forward<Args>(args))`. Any return value is stored as the result in the shared state. Any exception propagated from the execution of the deferred function is stored as the exceptional result in the shared state. The shared state is not made ready until the function has completed. The first call to a non-timed waiting function (32.9.5) on an asynchronous return object referring to this shared state invokes the deferred function in the thread that called the waiting function. Once evaluation of `invoke(std::move(g), std::move(xyz))` begins, the function is no longer considered deferred. [Note: If this policy is specified together with other policies, such as when using a policy value of `launch::async | launch::deferred`, implementations should defer invocation or the selection of the policy when no more concurrency can be effectively exploited. — end note]

If no value is set in the `launch` policy, or a value is set that is neither specified in this document nor by the implementation, the behavior is undefined.

Returns: An object of type `future<invoke_result_t<decay_t<F>, decay_t<Args>...>>` that refers to the shared state created by this call to `async`. [Note: If a future obtained from `async` is moved outside the local scope, other code that uses the future should be aware that the future’s destructor can block for the shared state to become ready. — end note]

Synchronization: Regardless of the provided policy argument,

- the invocation of `async` synchronizes with (6.9.2) the invocation of `f`. [Note: This statement applies even when the corresponding future object is moved to another thread. — end note] ; and
- the completion of the function `f` is sequenced before (6.9.2) the shared state is made ready. [Note: `f` might not be called at all, so its completion might never happen. — end note]

If the implementation chooses the `launch::async` policy,

- a call to a waiting function on an asynchronous return object that shares the shared state created by this `async` call shall block until the associated thread has completed, as if joined, or else time out (32.4.2.5);
- the associated thread completion synchronizes with (6.9.2) the return from the first function that successfully detects the ready status of the shared state or with the return from the last function that releases the shared state, whichever happens first.

Throws: `system_error` if `policy` == `launch::async` and the implementation is unable to start a new thread, or `std::bad_alloc` if memory for the internal data structures could not be allocated.

Error conditions:

- `resource_unavailable_try_again` — if `policy` == `launch::async` and the system is unable to start a new thread.

[Example:

```cpp
int work1(int value);
int work2(int value);
int work(int value) {
    auto handle = std::async([=]{ return work2(value); });
    int tmp = work1(value);
    return tmp + handle.get(); // #1
}
```
[Note: Line #1 might not result in concurrency because the `async` call uses the default policy, which may use `launch::deferred`, in which case the lambda might not be invoked until the `get()` call; in that case, `work1` and `work2` are called on the same thread and there is no concurrency. — end note] — end example]

### 32.9.10 Class template `packaged_task` [futures.task]

The class template `packaged_task` defines a type for wrapping a function or callable object so that the return value of the function or callable object is stored in a future when it is invoked.

When the `packaged_task` object is invoked, its stored task is invoked and the result (whether normal or exceptional) stored in the shared state. Any futures that share the shared state will then be able to access the stored result.
namespace std {
  template<class> class packaged_task; // not defined

  template<class R, class... ArgTypes>
  class packaged_task<R(ArgTypes...)> {
    public:
      // construction and destruction
      packaged_task() noexcept;
      template<class F>
        explicit packaged_task(F&& f);
      ~packaged_task();

      // no copy
      packaged_task(const packaged_task&) = delete;
      packaged_task& operator=(const packaged_task&) = delete;

      // move support
      packaged_task(packaged_task&& rhs) noexcept;
      packaged_task& operator=(packaged_task&& rhs) noexcept;
      void swap(packaged_task& other) noexcept;

      bool valid() const noexcept;

      // result retrieval
      future<R> get_future();

      // execution
      void operator()(ArgTypes...);
      void make_ready_at_thread_exit(ArgTypes...);
      void reset();
  };

  template<class R, class... ArgTypes>
  void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;
}

32.9.10.1 Member functions

packaged_task() noexcept;
  Effects: The object has no shared state and no stored task.

  template<class F>
    packaged_task(F&& f);
  Constraints: remove_cvref_t<F> is not the same type as packaged_task<R(ArgTypes...)>.
  Mandates: is_invocable_r_v<R, F&, ArgTypes...> is true.
  Preconditions: Invoking a copy of f behaves the same as invoking f.
  Effects: Constructs a new packaged_task object with a shared state and initializes the object's stored task
            with std::forward<F>(f).
  Throws: Any exceptions thrown by the copy or move constructor of f, or bad_alloc if memory for the internal
            data structures could not be allocated.

packaged_task(packaged_task&& rhs) noexcept;
  Effects: Transfers ownership of rhs's shared state to *this, leaving rhs with no shared state. Moves the stored
            task from rhs to *this.
  Postconditions: rhs has no shared state.

packaged_task& operator=(packaged_task&& rhs) noexcept;
  Effects:
    - Releases any shared state (32.9.5);
calls packaged_task(std::move(rhs)).swap(*this).

~packaged_task();

Effects: Abandons any shared state (32.9.5).

void swap(packaged_task& other) noexcept;

Effects: Exchanges the shared states and stored tasks of *this and other.

Postconditions: *this has the same shared state and stored task (if any) as other prior to the call to swap. other has the same shared state and stored task (if any) as *this prior to the call to swap.

bool valid() const noexcept;

Returns: true only if *this has a shared state.

future<R> get_future();

Returns: A future object that shares the same shared state as *this.

Synchronization: Calls to this function do not introduce data races (6.9.2) with calls to operator() or make_ready_at_thread_exit. [Note: Such calls need not synchronize with each other. — end note]

Throws: A future_error object if an error occurs.

Error conditions:
(17.1) — future_already_retrieved if get_future has already been called on a packaged_task object with the same shared state as *this.
(17.2) — no_state if *this has no shared state.

void operator()<ArgTypes...>(args...);

Effects: As if by 

INVOKE<R>(f, t1, t2, ..., tN) (20.14.3), where f is the stored task of *this and t1, t2, ..., tN are the values in args... If the task returns normally, the return value is stored as the asynchronous result in the shared state of *this, otherwise the exception thrown by the task is stored. The shared state of *this is made ready, and any threads blocked in a function waiting for the shared state of *this to become ready are unblocked.

Throws: A future_error exception object if there is no shared state or the stored task has already been invoked.

Error conditions:
(20.1) — promise_already_satisfied if the stored task has already been invoked.
(20.2) — no_state if *this has no shared state.

void make_ready_at_thread_exit(ArgTypes... args);

Effects: As if by 

INVOKE<R>(f, t1, t2, ..., tN) (20.14.3), where f is the stored task and t1, t2, ..., tN are the values in args... If the task returns normally, the return value is stored as the asynchronous result in the shared state of *this, otherwise the exception thrown by the task is stored. In either case, this is done without making that state ready (32.9.5) immediately. Schedules the shared state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws: future_error if an error condition occurs.

Error conditions:
(23.1) — promise_already_satisfied if the stored task has already been invoked.
(23.2) — no_state if *this has no shared state.

void reset();

Effects: As if *this = packaged_task(std::move(f)), where f is the task stored in *this. [Note: This constructs a new shared state for *this. The old state is abandoned (32.9.5). — end note]

Throws:
(25.1) — bad_alloc if memory for the new shared state could not be allocated.

§ 32.9.10.1
any exception thrown by the move constructor of the task stored in the shared state.

— future_error with an error condition of no_state if *this has no shared state.

32.9.10.2 Globals

```cpp
template<class R, class... ArgTypes>
void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;
```

1 Effects: As if by `x.swap(y)`. 
Annex A  (informative)
Grammar summary  [gram]

1 This summary of C++ grammar is intended to be an aid to comprehension. It is not an exact statement of the language. In particular, the grammar described here accepts a superset of valid C++ constructs. Disambiguation rules (8.9, 9.2, 11.8) must be applied to distinguish expressions from declarations. Further, access control, ambiguity, and type rules must be used to weed out syntactically valid but meaningless constructs.

A.1 Keywords  [gram.key]

New context-dependent keywords are introduced into a program by typedef (9.2.3), namespace (9.8.1), class (Clause 11), enumeration (9.7.1), and template (Clause 13) declarations.

typedef-name:
  identifier
  simple-template-id

namespace-name:
  identifier
  namespace-alias
	namespace-alias:

    export opt module pp-tokens opt ; new-line

pp-import:
    export opt import header-name pp-tokens opt ; new-line
    export opt import header-name-tokens pp-tokens opt ; new-line
    export opt import pp-tokens ; new-line

va-opt-replacement:
    __VA_OPT__ ( pp-tokens opt )
Annex B  (informative)

Implementation quantities [implimits]

1 Because computers are finite, C++ implementations are inevitably limited in the size of the programs they can successfully process. Every implementation shall document those limitations where known. This documentation may cite fixed limits where they exist, say how to compute variable limits as a function of available resources, or say that fixed limits do not exist or are unknown.

2 The limits may constrain quantities that include those described below or others. The bracketed number following each quantity is recommended as the minimum for that quantity. However, these quantities are only guidelines and do not determine compliance.

(2.1) Nesting levels of compound statements (8.4), iteration control structures (8.6), and selection control structures (8.5) [256].

(2.2) Nesting levels of conditional inclusion (15.2) [256].

(2.3) Pointer (9.3.3.1), array (9.3.3.4), and function (9.3.3.5) declarators (in any combination) modifying a class, arithmetic, or incomplete type in a declaration [256].

(2.4) Nesting levels of parenthesized expressions (7.5.3) within a full-expression [256].

(2.5) Number of characters in an internal identifier (5.10) or macro name (15.6) [1 024].

(2.6) Number of characters in an external identifier (5.10, 6.6) [1 024].

(2.7) External identifiers (6.6) in one translation unit [65 536].

(2.8) Identifiers with block scope declared in one block (6.4.3) [1 024].

(2.9) Structured bindings (9.6) introduced in one declaration [256].

(2.10) Macro identifiers (15.6) simultaneously defined in one translation unit [65 536].

(2.11) Parameters in one function definition (9.5.1) [256].

(2.12) Arguments in one function call (7.6.1.2) [256].

(2.13) Parameters in one macro definition (15.6) [256].

(2.14) Arguments in one macro invocation (15.6) [256].

(2.15) Characters in one logical source line (5.2) [65 536].

(2.16) Characters in a string-literal (5.13.5) (after concatenation (5.2)) [65 536].

(2.17) Size of an object (6.7.2) [262 144].

(2.18) Nesting levels for #include files (15.3) [256].

(2.19) Case labels for a switch statement (8.5.2) (excluding those for any nested switch statements) [16 384].

(2.20) Non-static data members (including inherited ones) in a single class (11.4) [16 384].

(2.21) Lambda-captures in one lambda-expression (7.5.5.2) [256].

(2.22) Enumeration constants in a single enumeration (9.7.1) [4 096].

(2.23) Levels of nested class definitions (11.4.10) in a single member-specification [256].

(2.24) Functions registered by atexit() (17.5) [32].

(2.25) Functions registered by at_quick_exit() (17.5) [32].

(2.26) Direct and indirect base classes (11.7) [16 384].

(2.27) Direct base classes for a single class (11.7) [1 024].

(2.28) Class members declared in a single member-specification (including member functions) (11.4) [4 096].

(2.29) Final overriding virtual functions in a class, accessible or not (11.7.2) [16 384].

(2.30) Direct and indirect virtual bases of a class (11.7.1) [1 024].

(2.31) Static data members of a class (11.4.8.2) [1 024].
— Friend declarations in a class (11.9.3) [4 096].
— Access control declarations in a class (11.9.1) [4 096].
— Member initializers in a constructor definition (11.10.2) [6 144].
— `initializer-clauses` in one `braced-init-list` (9.4) [16 384].
— Scope qualifications of one identifier (7.5.4.2) [256].
— Nested `linkage-specifications` (9.11) [1 024].
— Recursive `constexpr` function invocations (9.2.5) [512].
— Full-expressions evaluated within a core constant expression (7.7) [1 048 576].
— Template parameters in a template declaration (13.2) [1 024].
— Recursively nested template instantiations (13.9.1), including substitution during template argument deduction (13.10.2) [1 024].
— Handlers per try block (14.4) [256].
— Number of placeholders (20.14.14.4) [10].
Annex C  (informative)
Compatibility

C.1  C++ and ISO C++ 2017

This subclause lists the differences between C++ and ISO C++ 2017 (ISO/IEC 14882:2017, Programming Languages — C++), by the chapters of this document.

C.1.1  Clause 5: lexical conventions

1  Affected subclauses: 5.4, 10.1, 10.3, 15.1, 15.4, and 15.5
Change: New identifiers with special meaning.
Rationale: Required for new features.
Effect on original feature: Logical lines beginning with module or import may be interpreted differently in this International Standard. [Example:

```cpp
class module {}
module m1;        // was variable declaration; now module-declaration
module *m2;       // variable declaration

class import {}
import j1;        // was variable declaration; now import-declaration
::import j2;      // variable declaration
```
— end example]

2  Affected subclause: 5.8
Change: header-name tokens are formed in more contexts.
Rationale: Required for new features.
Effect on original feature: When the identifier import is followed by a < character, a header-name token may be formed. [Example:

```cpp
template<typename> class import {}; import<int> f(); // ill-formed; previously well-formed ::import<int> g(); // OK
```
— end example]

3  Affected subclause: 5.11
Change: New keywords.
Rationale: Required for new features.

(1) — The char8_t keyword is added to differentiate the types of ordinary and UTF-8 literals (5.13.5).
(1.2) — The concept keyword is added to enable the definition of concepts (13.7.8).
(1.3) — The consteval keyword is added to declare immediate functions (9.2.5).
(1.4) — The constinit keyword is added to prevent unintended dynamic initialization (9.2.6).
(1.5) — The co_await, co_yield, and co_return keywords are added to enable the definition of coroutines (9.5.4).
(1.6) — The requires keyword is added to introduce constraints through a requires-clause (13.1) or a requires-expression (7.5.7).
Effect on original feature: Valid C++ 2017 code using char8_t, concept, consteval, constinit, co_await, co_yield, co_return, or requires as an identifier is not valid in this International Standard.

4  Affected subclause: 5.12
Change: New operator <=>
Rationale: Necessary for new functionality.
Effect on original feature: Valid C++ 2017 code that contains a <= token immediately followed by a > token may be ill-formed or have different semantics in this International Standard:

```cpp
namespace N {
    struct X {};
```
bool operator<=(X, X);
    template<bool(X, X)> struct Y {}
    Y<operator<=> y;                                                                 // ill-formed; previously well-formed

5  Affected subclause: 5.13
Change: Type of UTF-8 string and character literals.
Rationale: Required for new features. The changed types enable function overloading, template specialization, and type deduction to distinguish ordinary and UTF-8 string and character literals.
Effect on original feature: Valid C++ 2017 code that depends on UTF-8 string literals having type “array of const char” and UTF-8 character literals having type “char” is not valid in this International Standard.

const auto *u8s = u8"text";                                                 // u8s previously deduced as const char*; now deduced as const char8_t*
const char *ps = u8s;                                                     // ill-formed; previously well-formed
auto u8c = u8'c';                                                        // u8c previously deduced as char; now deduced as char8_t
char *pc = &u8c;                                                         // ill-formed; previously well-formed
std::string s = u8"text";                                                // ill-formed; previously well-formed
void f(const char *s);
    f(u8"text");                                                        // ill-formed; previously well-formed

    template<typename> struct ct;
    template<> struct ct<char> {
        using type = char;
    };
    ct<decltype(u8'c')>::type x;                                            // ill-formed; previously well-formed.

C.1.2 Clause 6: basics [diff.cpp17.basic]

1  Affected subclause: 6.7.3
Change: A pseudo-destructor call ends the lifetime of the object to which it is applied.
Rationale: Increase consistency of the language model.
Effect on original feature: Valid ISO C++ 2017 code may be ill-formed or have undefined behavior in this International Standard. [Example:

```cpp
int f() {
    int a = 123;
    using T = int;
    a.~T();
    return a;                                                            // undefined behavior; previously returned 123
}

@end example]
```

2  Affected subclause: 6.9.2.1
Change: Except for the initial release operation, a release sequence consists solely of atomic read-modify-write operations.
Rationale: Removal of rarely used and confusing feature.
Effect on original feature: If a memory_order_release atomic store is followed by a memory_order_relaxed store to the same variable by the same thread, then reading the latter value with a memory_order_acquire load no longer provides any “happens before” guarantees, even in the absence of intervening stores by another thread.

C.1.3 Clause 7: expressions [diff.cpp17.expr]

1  Affected subclause: 7.5.5.2
Change: Implicit lambda capture may capture additional entities.
Rationale: Rule simplification, necessary to resolve interactions with constexpr if.
Effect on original feature: Lambdas with a capture-default may capture local entities that were not captured in C++ 2017 if those entities are only referenced in contexts that do not result in an odr-use.

C.1.4 Clause 9: declarations [diff.cpp17.dcl.dcl]

1  Affected subclause: 9.2.3
Change: Unnamed classes with a typedef name for linkage purposes can contain only C-compatible constructs.
Rationale: Necessary for implementability.
Effect on original feature: Valid C++ 2017 code may be ill-formed in this International Standard.

```c
typedef struct {
    void f() {}
} S;
```

2 Affected subclause: 9.3.3.6
Change: A function cannot have different default arguments in different translation units.
Rationale: Required for modules support.
Effect on original feature: Valid C++ 2017 code may be ill-formed in this International Standard, with no diagnostic required.

```c
// Translation unit 1
int f(int a = 42);
int g() { return f(); }

// Translation unit 2
int f(int a = 76) { return a; } // ill-formed, no diagnostic required; previously well-formed
int g();
int main() { return g(); } // used to return 42
```

3 Affected subclause: 9.4.1
Change: A class that has user-declared constructors is never an aggregate.
Rationale: Remove potentially error-prone aggregate initialization which may apply notwithstanding the declared constructors of a class.
Effect on original feature: Valid C++ 2017 code that aggregate-initializes a type with a user-declared constructor may be ill-formed or have different semantics in this International Standard.

```c
struct A {
    A() = delete;
};

struct B {
    B() = default;
    int i = 0;
};

struct C {
    C(C&&) = default;
    int a, b;
};

A a{}; // ill-formed; previously well-formed
B b = {1}; // ill-formed; previously well-formed
auto* c = new C{2, 3}; // ill-formed; previously well-formed

struct Y;

struct X {
    operator Y();
};

struct Y {
    Y(const Y&) = default;
    X x;
};

Y y{x{}}; // copy constructor call; previously aggregate-initialization
```

4 Affected subclause: 9.4.4
Change: Boolean conversion from a pointer or pointer-to-member type is now a narrowing conversion.
Rationale: Catches bugs.
Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard. For example:

```c
bool y[] = { "bc" }; // ill-formed; previously well-formed
```
C.1.5 Clause 11: classes

1 Affected subclauses: 11.4.4 and 11.4.7.2

Change: The class name can no longer be used parenthesized immediately after an explicit decl-specifier in a constructor declaration. The conversion-function-id can no longer be used parenthesized immediately after an explicit decl-specifier in a conversion function declaration.

Rationale: Necessary for new functionality.

Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard. For example:

```cpp
struct S {
    explicit (S)(const S&); // ill-formed; previously well-formed
    explicit (operator int)(); // ill-formed; previously well-formed
    explicit(true) (S)(int);    // OK
};
```

2 Affected subclauses: 11.4.4 and 11.4.6

Change: A simple-template-id is no longer valid as the declarator-id of a constructor or destructor.

Rationale: Remove potentially error-prone option for redundancy.

Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard. For example:

```cpp
template<class T>
struct A {
    A<T>();       // error: simple-template-id not allowed for constructor
    A<int>();     // OK, injected-class-name used
    "A<T>();";   // error: simple-template-id not allowed for destructor
};
```

3 Affected subclause: 11.10.5

Change: A function returning an implicitly movable entity may invoke a constructor taking an rvalue reference to a type different from that of the returned expression. Function and catch-clause parameters can be thrown using move constructors.

Rationale: Side effect of making it easier to write more efficient code that takes advantage of moves.

Effect on original feature: Valid C++ 2017 code may fail to compile or have different semantics in this International Standard. For example:

```cpp
struct base {
    base();
    base(base const &);
private:
    base(base &&);
};

struct derived : base {}

base f(base b) {
    throw b; // error: base(base &&) is private
derived d;
    return d; // error: base(base &&) is private
}

struct S {
    S(const char *s) : m(s) { }
    S(const S&) = default;
    S(S&& other) : m(other.m) { other.m = nullptr; }
    const char * m;
};

S consume(S&& s) { return s; }

void g() {
    S s("text");
    consume(static_cast<S&&>(s));
    char c = s.m;    // undefined behavior; previously ok
}
```
C.1.6 Clause 12: overloading

Affected subclause: 12.4.1.2

Change: Equality and inequality expressions can now find reversed and rewritten candidates.

Rationale: Improve consistency of equality with three-way comparison and make it easier to write the full complement of equality operations.

Effect on original feature: Equality and inequality expressions between two objects of different types, where one is convertible to the other, could invoke a different operator. Equality and inequality expressions between two objects of the same type could become ambiguous.

```cpp
struct A {
    operator int() const;
};

bool operator==(A, int);  // #1
// #2 is built-in candidate: bool operator==(int, int);
// #3 is built-in candidate: bool operator!=(int, int);

int check(A x, A y) {
    return (x == y) +  // ill-formed; previously well-formed
           (10 == x) +  // calls #1, previously selected #2
           (10 != x);  // calls #1, previously selected #3
}
```

C.1.7 Clause 13: templates

Affected subclause: 13.3

Change: An unqualified-id that is followed by a < and for which name lookup finds nothing or finds a function will be treated as a template-name in order to potentially cause argument dependent lookup to be performed.

Rationale: It was problematic to call a function template with an explicit template argument list via argument dependent lookup because of the need to have a template with the same name visible via normal lookup.

Effect on original feature: Previously valid code that uses a function name as the left operand of a < operator would become ill-formed.

```cpp
struct A {}
bool operator<(void (*fp)(), A);
void f() {}
int main() {
    A a;
    f < a;  // ill-formed; previously well-formed
    (f) < a;  // still well formed
}
```

C.1.8 Clause 14: exception handling

Affected subclause: 14.5

Change: Remove throw() exception specification.

Rationale: Removal of obsolete feature that has been replaced by noexcept.

Effect on original feature: A valid C++ 2017 function declaration, member function declaration, function pointer declaration, or function reference declaration that uses throw() for its exception specification will be rejected as ill-formed in this International Standard. It should simply be replaced with noexcept for no change of meaning since C++ 2017. [Note: There is no way to write a function declaration that is non-throwing in this International Standard and is also non-throwing in C++ 2003 except by using the preprocessor to generate a different token sequence in each case. — end note]

C.1.9 Clause 16: library introduction

Affected subclause: 16.5.1.2

Change: New headers.

Rationale: New functionality.

Effect on original feature: The following C++ headers are new: <barrier> (32.8.2.1), <bit> (26.5.2), <charconv> (20.19.1), <compare> (17.11.1), <concepts> (18.3), <coroutine> (17.12.1), <format> (20.20.1), <latch> (32.8.1.1), <numbers> (26.9.1), <ranges> (24.2), <semaphore> (32.7.1), <source_location> (17.8.1), <span> (22.7.2), <stop_token> (32.3.2), <syncstream> (29.10.1), and <version> (17.3.1). Valid C++ 2017 code that #includes headers with these names may be invalid in this International Standard.

§ C.1.9 1604
Affected subclause: 16.5.1.2
Change: Remove vacuous C++ header files.
Rationale: The empty headers implied a false requirement to achieve C compatibility with the C++ headers.
Effect on original feature: A valid C++ 2017 program that #includes any of the following headers may fail to compile: `<complex>`, `<ciso646>`, `<cstdalgin>`, `<cstdbool>`, and `<ctgmath>`. To retain the same behavior:

- a #include of `<complex>` can be replaced by a #include of `<complex>` (26.4.1),
- a #include of `<ctgmath>` can be replaced by a #include of `<cmath>` (26.8.1) and a #include of `<complex>`, and
- a #include of `<ciso646>`, `<cstdalgin>`, or `<cstdbool>` can simply be removed.

C.1.10 Clause 22: containers library

Affected subclauses: 22.3.9 and 22.3.10
Change: Return types of remove, remove_if, and unique changed from void to container::size_type.
Rationale: Improve efficiency and convenience of finding number of removed elements.
Effect on original feature: Code that depends on the return types might have different semantics in this International Standard. Translation units compiled against this version of C++ may be incompatible with translation units compiled against C++ 2017, either failing to link or having undefined behavior.

C.1.11 Clause 23: iterators library

Affected subclause: 23.3.2.3
Change: The specialization of iterator_traits for void* and for function pointer types no longer contains any nested typedefs.
Rationale: Corrects an issue misidentifying pointer types that are not incrementable as iterator types.
Effect on original feature: A valid C++ 2017 program that relies on the presence of the typedefs may fail to compile, or have different behavior.

C.1.12 Clause 25: algorithms library

Affected subclause: 25.2
Change: The number and order of deducible template parameters for algorithm declarations is now unspecified, instead of being as-declared.
Rationale: Increase implementor freedom and allow some function templates to be implemented as function objects with templated call operators.
Effect on original feature: A valid C++ 2017 program that passes explicit template arguments to algorithms not explicitly specified to allow such in this version of C++ may fail to compile or have undefined behavior.

C.1.13 Clause 29: input/output library

Affected subclause: 29.7.4.2.3
Change: Character array extraction only takes array types.
Rationale: Increase safety via preventing buffer overflow at compile time.
Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard:

```cpp
auto p = new char[100];
char q[100];
std::cin >> std::setw(20) >> p; // ill-formed; previously well-formed
std::cin >> std::setw(20) >> q; // OK
```

Affected subclause: 29.7.5.2.4
Change: Overload resolution for ostream inserters used with UTF-8 literals.
Rationale: Required for new features.
Effect on original feature: Valid C++ 2017 code that passes UTF-8 literals to basic_ostream<char, ...>::operator<< or basic_ostream<char16_t, ...>::operator<< is now ill-formed.

```cpp
std::cout << u8"text"; // previously called operator<<(const char*) and printed a string;
               // now ill-formed
std::cout << u8'X';  // previously called operator<<(char) and printed a character;
               // now ill-formed
```

Affected subclause: 29.7.5.2.4
Change: Overload resolution for ostream inserters used with wchar_t, char16_t, or char32_t types.
Rationale: Removal of surprising behavior.
Effect on original feature: Valid C++ 2017 code that passes wchar_t, char16_t, or char32_t characters or strings to basic_ostream<char, ...>::operator<< or that passes char16_t or char32_t characters or strings to basic_ostream<wchar_t, ...>::operator<< is now ill-formed.

```cpp
std::cout << u"text";  // previously formatted the string as a pointer value;
```

```cpp
std::cout << u'X';  // previously formatted the character as an integer value;
```

Affected subclause: 29.11.7

Change: Return type of filesystem path format observer member functions.

Rationale: Required for new features.

Effect on original feature: Valid C++ 2017 code that depends on the u8string() and generic_u8string() member functions of std::filesystem::path returning std::string is not valid in this International Standard.

```cpp
std::filesystem::path p;
std::string s1 = p.u8string(); // ill-formed; previously well-formed
```

```cpp
std::string s2 = p.generic_u8string(); // ill-formed; previously well-formed
```

C.1.14 Annex D: compatibility features

Change: Remove uncaught_exception.

Rationale: The function did not have a clear specification when multiple exceptions were active, and has been superseded by uncaught_exceptions.

Effect on original feature: A valid C++ 2017 program that calls std::uncaught_exception may fail to compile. It might be revised to use std::uncaught_exceptions instead, for clear and portable semantics.

Change: Remove support for adaptable function API.

Rationale: The deprecated support relied on a limited convention that could not be extended to support the general case or new language features. It has been superseded by direct language support with decltype, and by the std::bind and std::not_fn function templates.

Effect on original feature: A valid C++ 2017 program that relies on the presence of result_type, argument_type, first_argument_type, or second_argument_type in a standard library class may fail to compile. A valid C++ 2017 program that calls not1 or not2, or uses the class templates unary_negate or binary_negate, may fail to compile.

Change: Remove redundant members from std::allocator.

Rationale: std::allocator was overspecified, encouraging direct usage in user containers rather than relying on std::allocator_traits, leading to poor containers.

Effect on original feature: A valid C++ 2017 program that directly makes use of the pointer, const_pointer, reference, const_reference, rebind, address, construct, destroy, or max_size members of std::allocator, or that directly calls allocate with an additional hint argument, may fail to compile.

Change: Remove raw_storage_iterator.

Rationale: The iterator encouraged use of algorithms that might throw exceptions, but did not return the number of elements successfully constructed that might need to be destroyed in order to avoid leaks.

Effect on original feature: A valid C++ 2017 program that uses this iterator class may fail to compile.

Change: Remove temporary buffers API.

Rationale: The temporary buffer facility was intended to provide an efficient optimization for small memory requests, but there is little evidence this was achieved in practice, while requiring the user to provide their own exception-safe wrappers to guard use of the facility in many cases.

Effect on original feature: A valid C++ 2017 program that calls get_temporary_buffer or return_temporary_buffer may fail to compile.

Change: Remove shared_ptr::unique.

Rationale: The result of a call to this member function is not reliable in the presence of multiple threads and weak pointers. The member function use_count is similarly unreliable, but has a clearer contract in such cases, and remains available for well defined use in single-threaded cases.

Effect on original feature: A valid C++ 2017 program that calls unique on a shared_ptr object may fail to compile.

Change: Remove deprecated type traits.

Rationale: The traits had unreliable or awkward interfaces. The is_literal_type trait provided no way to detect which subset of constructors and member functions of a type were declared constexpr. The result_of trait had a surprising syntax that could not report the result of a regular function type. It has been superseded by the
C.2 C++ and ISO C++ 2014

This subclause lists the differences between C++ and ISO C++ 2014 (ISO/IEC 14882:2014, *Programming Languages — C++*), in addition to those listed above, by the chapters of this document.

C.2.1 Clause 5: lexical conventions

**Affected subclause:** 5.2

**Change:** Removal of trigraph support as a required feature.

**Rationale:** Prevents accidental uses of trigraphs in non-raw string literals and comments.

**Effect on original feature:** Valid C++ 2014 code that uses trigraphs may not be valid or may have different semantics in this International Standard. Implementations may choose to translate trigraphs as specified in C++ 2014 if they appear outside of a raw string literal, as part of the implementation-defined mapping from physical source file characters to the basic source character set.

C.2.2 Clause 7: expressions

**Affected subclauses:** 7.6.1.5 and 7.6.2.2

**Change:** Remove increment operator with `bool` operand.

**Rationale:** Obsolete feature with occasionally surprising semantics.

**Effect on original feature:** A valid C++ 2014 expression utilizing the increment operator on a `bool` lvalue is ill-formed in this International Standard. Note that this might occur when the lvalue has a type given by a template parameter.

C.2.3 Clause 9: declarations

**Affected subclause:** 9.2.1

**Change:** Removal of `register` storage-class-specifier.

**Rationale:** Enable repurposing of deprecated keyword in future revisions of this International Standard.

**Effect on original feature:** A valid C++ 2014 declaration utilizing the `register` storage-class-specifier is ill-formed in this International Standard. The specifier can simply be removed to retain the original meaning.

C.2.3.1 Clause 9.3: exceptions

**Affected subclause:** 9.3.3.5

**Change:** Make exception specifications be part of the type system.

**Rationale:** Improve type-safety.

```c
#define F(a) b ## a
int b0p = F(0p+0); // ill-formed; equivalent to "int b0p = b0p + 0;" in C++ 2014
```
Effect on original feature: Valid C++ 2014 code may fail to compile or change meaning in this International Standard. For example:

```cpp
void g1() noexcept;
void g2();
template<class T> int f(T *, T *);
int x = f(g1, g2);  // ill-formed; previously well-formed
```

Affected subclause: 9.4.1
Change: Definition of an aggregate is extended to apply to user-defined types with base classes.
Rationale: To increase convenience of aggregate initialization.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard. Initialization from an empty initializer list will perform aggregate initialization instead of invoking a default constructor for the affected types. For example:

```cpp
struct derived;
struct base {
    friend struct derived;
private:
    base();
};
struct derived : base {};
```

derived d1{};  // error; the code was well-formed in C++ 2014
derived d2;  // still OK

C.2.4 Clause 11: classes

Affected subclause: 11.10.3
Change: Inheriting a constructor no longer injects a constructor into the derived class.
Rationale: Better interaction with other language features.
Effect on original feature: Valid C++ 2014 code that uses inheriting constructors may not be valid or may have different semantics. A `using-declaration` that names a constructor now makes the corresponding base class constructors visible to initializations of the derived class rather than declaring additional derived class constructors.

```cpp
struct A {
    template<typename T> A(T, typename T::type = 0);
    A(int);
};
struct B : A {
    using A::A;
    B(int);
};
B b(42L);
// now calls B(int), used to call B<long>(long),
// which called A(int) due to substitution failure
// in A<long>(long).
```

C.2.5 Clause 13: templates

Affected subclause: 13.10.2.5
Change: Allowance to deduce from the type of a non-type template argument.
Rationale: In combination with the ability to declare non-type template arguments with placeholder types, allows partial specializations to decompose from the type deduced for the non-type template argument.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard. For example:

```cpp
template <int N> struct A;
template <typename T, T N> int foo(A<N> *) = delete;
void foo(void *);
void bar(A<0> *p) {
    foo(p);  // ill-formed; previously well-formed
}
```

C.2.6 Clause 14: exception handling

Affected subclause: 14.5
Change: Remove dynamic exception specifications.
Rationale: Dynamic exception specifications were a deprecated feature that was complex and brittle in use. They interacted badly with the type system, which became a more significant issue in this International Standard where (non-dynamic) exception specifications are part of the function type.

Effect on original feature: A valid C++ 2014 function declaration, member function declaration, function pointer declaration, or function reference declaration, if it has a potentially throwing dynamic exception specification, will be rejected as ill-formed in this International Standard. Violating a non-throwing dynamic exception specification will call terminate rather than unexpected and might not perform stack unwinding prior to such a call.

C.2.7 Clause 16: library introduction

1  Affected subclause: 16.5.1.2
   Change: New headers.
   Rationale: New functionality.
   Effect on original feature: The following C++ headers are new: <any> (20.8.1), <charconv> (20.19.1), <execution> (20.18.2), <filesystem> (29.11.5), <memory_resource> (20.12.1), <optional> (20.6.2), <string_view> (21.4.1), and <variant> (20.7.2). Valid C++ 2014 code that #includes headers with these names may be invalid in this International Standard.

2  Affected subclause: 16.5.4.2.3
   Change: New reserved namespaces.
   Rationale: Reserve namespaces for future revisions of the standard library that might otherwise be incompatible with existing programs.
   Effect on original feature: The global namespaces std followed by an arbitrary sequence of digits (5.10) are reserved for future standardization. Valid C++ 2014 code that uses such a top-level namespace, e.g., std2, may be invalid in this International Standard.

C.2.8 Clause 20: general utilities library

1  Affected subclause: 20.14.16
   Change: Constructors taking allocators removed.
   Rationale: No implementation consensus.
   Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. Specifically, constructing a std::function with an allocator is ill-formed and uses-allocator construction will not pass an allocator to std::function constructors in this International Standard.

2  Affected subclause: 20.11.3
   Change: Different constraint on conversions from unique_ptr.
   Rationale: Adding array support to shared_ptr, via the syntax shared_ptr<T[]> and shared_ptr<T[N]>. 
   Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. For example:
   ```c++
   #include <memory>
   std::unique_ptr<int[]> arr(new int[1]);
   std::shared_ptr<int> ptr(std::move(arr));  // error: int(*)[] is not compatible with int*
   ```

C.2.9 Clause 21: strings library

1  Affected subclause: 21.3.2
   Change: Non-const .data() member added.
   Rationale: The lack of a non-const .data() differed from the similar member of std::vector. This change regularizes behavior for this International Standard.
   Effect on original feature: Overloaded functions which have differing code paths for char* and const char* arguments will execute differently when called with a non-const string’s .data() member in this International Standard.
   ```c++
   int f(char *) = delete;
   int f(const char *);
   string s;
   int x = f(s.data());  // ill-formed; previously well-formed
   ```

C.2.10 Clause 22: containers library

1  Affected subclause: 22.2.6
   Change: Requirements change:
   Rationale: Increase portability, clarification of associative container requirements.
**Effect on original feature:** Valid C++ 2014 code that attempts to use associative containers having a comparison object with non-const function call operator may fail to compile in this International Standard:

```cpp
#include <set>

struct compare
{
    bool operator()(int a, int b)
    {
        return a < b;
    }
};

int main()
{
    const std::set<int, compare> s;
    s.find(0);
}
```

### C.2.11 Annex D: compatibility features

1. **Change:** The class templates `auto_ptr`, `unary_function`, and `binary_function`, the function templates `random_shuffle`, and the function templates (and their return types) `ptr_fun`, `mem_fun`, `mem_fun_ref`, `bind1st`, and `bind2nd` are not defined.
   **Rationale:** Superseded by new features.
   **Effect on original feature:** Valid C++ 2014 code that uses these class templates and function templates may fail to compile in this International Standard.

2. **Change:** Remove old iostreams members [depr.ios.members].
   **Rationale:** Redundant feature for compatibility with pre-standard code has served its time.
   **Effect on original feature:** A valid C++ 2014 program using these identifiers may be ill-formed in this International Standard.

### C.3 C++ and ISO C++ 2011

This subclause lists the differences between C++ and ISO C++ 2011 (ISO/IEC 14882:2011, *Programming Languages — C++*), in addition to those listed above, by the chapters of this document.

#### C.3.1 Clause 5: lexical conventions

1. **Affected subclause:** 5.9
   **Change:** `pp-number` can contain one or more single quotes.
   **Rationale:** Necessary to enable single quotes as digit separators.
   **Effect on original feature:** Valid C++ 2011 code may fail to compile or may change meaning in this International Standard. For example, the following code is valid both in C++ 2011 and in this International Standard, but the macro invocation produces different outcomes because the single quotes delimit a `character-literal` in C++ 2011, whereas they are digit separators in this International Standard:

   ```cpp
   #define M(x, ...) __VA_ARGS__
   // int x[2] = { 3'4, 5 }; — this International Standard
   ```

#### C.3.2 Clause 6: basics

1. **Affected subclause:** 6.7.5.4.2
   **Change:** New usual (non-placement) deallocator.
   **Rationale:** Required for sized deallocation.
   **Effect on original feature:** Valid C++ 2011 code could declare a global placement allocation function and deallocation function as follows:

   ```cpp
   void* operator new(std::size_t, std::size_t);
   void operator delete(void*, std::size_t) noexcept;
   ```

   In this International Standard, however, the declaration of `operator delete` might match a predefined usual (non-placement) `operator delete` (6.7.5.4). If so, the program is ill-formed, as it was for class member allocation functions and deallocation functions (7.6.2.7).

C.3.3
1

Clause 7: expressions

[diff.cpp11.expr]

Affected subclause: 7.6.16
Change: A conditional expression with a throw expression as its second or third operand keeps the type and value
category of the other operand.
Rationale: Formerly mandated conversions (lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer
(7.3.3) standard conversions), especially the creation of the temporary due to lvalue-to-rvalue conversion, were
considered gratuitous and surprising.
Effect on original feature: Valid C++ 2011 code that relies on the conversions may behave differently in this
International Standard:
struct S {
int x = 1;
void mf() { x = 2; }
};
int f(bool cond) {
S s;
(cond ? s : throw 0).mf();
return s.x;
}

In C++ 2011, f(true) returns 1. In this International Standard, it returns 2.
sizeof(true ? "" : throw 0)

In C++ 2011, the expression yields sizeof(const char*). In this International Standard, it yields sizeof(const
char[1]).

C.3.4
1

Clause 9: declarations

[diff.cpp11.dcl.dcl]

Affected subclause: 9.2.5
Change: constexpr non-static member functions are not implicitly const member functions.
Rationale: Necessary to allow constexpr member functions to mutate the object.
Effect on original feature: Valid C++ 2011 code may fail to compile in this International Standard. For example, the
following code is valid in C++ 2011 but invalid in this International Standard because it declares the same member
function twice with different return types:
struct S {
constexpr const int &f();
int &f();
};

2

Affected subclause: 9.4.1
Change: Classes with default member initializers can be aggregates.
Rationale: Necessary to allow default member initializers to be used by aggregate initialization.
Effect on original feature: Valid C++ 2011 code may fail to compile or may change meaning in this International
Standard. For example:
struct S {
int m = 1;
};
struct X {
operator int();
operator S();
};
X a{};
S b{a};

C.3.5
1

// Aggregate in C++ 2014 onwards.

// uses copy constructor in C++ 2011,
// performs aggregate initialization in this International Standard

Clause 16: library introduction

[diff.cpp11.library]

Affected subclause: 16.5.1.2
Change: New header.
Rationale: New functionality.
Effect on original feature: The C++ header <shared_mutex> (32.5.2) is new. Valid C++ 2011 code that #includes
a header with that name may be invalid in this International Standard.

§ C.3.5

1611


C.3.6 Clause 29: input/output library

Affected subclause: 29.12
Change: `gets` is not defined.
Rationale: Use of `gets` is considered dangerous.
Effect on original feature: Valid C++ 2011 code that uses the `gets` function may fail to compile in this International Standard.

C.4 C++ and ISO C++ 2003

This subclause lists the differences between C++ and ISO C++ 2003 (ISO/IEC 14882:2003, Programming Languages — C++), in addition to those listed above, by the chapters of this document.

C.4.1 Clause 5: lexical conventions

Affected subclause: 5.4
Change: New kinds of `string-literals`.
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. Specifically, macros named `R`, `u8`, `u8R`, `u`, `uR`, `U`, `UR`, or `LR` will not be expanded when adjacent to a `string-literal` but will be interpreted as part of the `string-literal`. For example:

```c++
#define u8 "abc"
const char* s = u8"def";
// Previously "abcdef", now "def"
```

Affected subclause: 5.4
Change: User-defined literal string support.
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:

```c++
#define _x "there"
"hello"_x
// #1
```

Previously, #1 would have consisted of two separate preprocessing tokens and the macro `_x` would have been expanded. In this International Standard, #1 consists of a single preprocessing token, so the macro is not expanded.

Affected subclause: 5.11
Change: New keywords.
Rationale: Required for new features.
Effect on original feature: Added to Table 5, the following identifiers are new keywords: `alignas`, `alignof`, `char16_t`, `char32_t`, `constexpr`, `decltype`, `noexcept`, `nullptr`, `static_assert`, and `thread_local`. Valid C++ 2003 code using these identifiers is invalid in this International Standard.

C.4.2 Clause 7: expressions

Affected subclause: 7.3.11
Change: Only literals are integer null pointer constants.
Rationale: Removing surprising interactions with templates and constant expressions.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:

```c++
void f(void *);  // #1
void f(...);    // #2
template<int N> void g() {
    f(0*N);      // calls #2; used to call #1
}
```

Affected subclause: 7.6.5
Change: Specify rounding for results of integer `/` and `%`.
Rationale: Increase portability, C99 compatibility.
Effect on original feature: Valid C++ 2003 code that uses integer division rounds the result toward 0 or toward negative infinity, whereas this International Standard always rounds the result toward 0.

Affected subclause: 7.6.14
Change: && is valid in a type-name.
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:

```c++
bool b1 = new int && false; // previously false, now ill-formed
struct S { operator int() { } };
bool b2 = &S::operator int && false; // previously false, now ill-formed
```

C.4.3 Clause 9: declarations

Affected subclause: 9.2
Change: Remove auto as a storage class specifier.
Rationale: New feature.
Effect on original feature: Valid C++ 2003 code that uses the keyword auto as a storage class specifier may be invalid in this International Standard. In this International Standard, auto indicates that the type of a variable is to be deduced from its initializer expression.

Affected subclause: 9.4.4
Change: Narrowing restrictions in aggregate initializers.
Rationale: Catches bugs.
Effect on original feature: Valid C++ 2003 code may fail to compile in this International Standard. For example, the following code is valid in C++ 2003 but invalid in this International Standard because double to int is a narrowing conversion:

```c++
int x[] = { 2.0 };
```

C.4.4 Clause 11: classes

Affected subclauses: 11.4.4.1, 11.4.6, 11.4.4.2, and 11.4.5
Change: Implicitly-declared special member functions are defined as deleted when the implicit definition would have been ill-formed.
Rationale: Improves template argument deduction failure.
Effect on original feature: A valid C++ 2003 program that uses one of these special member functions in a context where the definition is not required (e.g., in an expression that is not potentially evaluated) becomes ill-formed.

Affected subclause: 11.4.6
Change: User-declared destructors have an implicit exception specification.
Rationale: Clarification of destructor requirements.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. In particular, destructors that throw exceptions will call std::terminate (without calling std::unexpected) if their exception specification is non-throwing.

C.4.5 Clause 13: templates

Affected subclause: 13.2
Change: Remove export.
Rationale: No implementation consensus.
Effect on original feature: A valid C++ 2003 declaration containing export is ill-formed in this International Standard.

Affected subclause: 13.4
Change: Remove whitespace requirement for nested closing template right angle brackets.
Rationale: Considered a persistent but minor annoyance. Template aliases representing non-class types would exacerbate whitespace issues.
Effect on original feature: Change to semantics of well-defined expression. A valid C++ 2003 expression containing a right angle bracket (“>”) followed immediately by another right angle bracket may now be treated as closing two templates. For example, the following code is valid in C++ 2003 because “>>” is a right-shift operator, but invalid in this International Standard because “>>” closes two templates.

```c++
template <class T> struct X { };
template <int N> struct Y { };
```
Affected subclause: 13.8.4.2
Change: Allow dependent calls of functions with internal linkage.
Rationale: Overly constrained, simplify overload resolution rules.
Effect on original feature: A valid C++ 2003 program could get a different result than this International Standard.

C.4.6 Clause 16: library introduction [diff.cpp03.library]

Affected: Clause 16 – Clause 32
Change: New reserved identifiers.
Rationale: Required by new features.
Effect on original feature: Valid C++ 2003 code that uses any identifiers added to the C++ standard library by this International Standard may fail to compile or produce different results in this International Standard. A comprehensive list of identifiers used by the C++ standard library can be found in the Index of Library Names in this International Standard.

Affected subclause: 16.5.1.2
Change: New headers.
Rationale: New functionality.
Effect on original feature: The following C++ headers are new: <array> (22.3.2), <atomic> (31.2), <chrono> (27.2), <codecvt> (D.20.1), <condition_variable> (32.6.1), <forward_list> (22.3.4), <future> (32.9.2), <initializer_list> (17.10.1), <mutex> (32.5.1), <random> (26.6.1), <ratio> (20.16.2), <regex> (30.4), <scoped_allocator> (20.13.1), <system_error> (19.5.1), <thread> (32.4.1), <tuple> (20.5.2), <typeindex> (20.17.1), <type_traits> (20.15.2), <unordered_map> (22.5.2), and <unordered_set> (22.5.3). In addition the following C compatibility headers are new: <cfenv> (26.3.1), <cinttypes> (29.12.2), <cstdint> (17.4.1), and <cuchar> (21.5.5). Valid C++ 2003 code that #include s headers with these names may be invalid in this International Standard.

Affected subclause: 16.5.3.2
Effect on original feature: Function swap moved to a different header
Rationale: Remove dependency on <algorithm> (25.4) for swap.

Affected subclause: 16.5.4.2.2
Change: New reserved namespace.
Rationale: New functionality.
Effect on original feature: The global namespace posix is now reserved for standardization. Valid C++ 2003 code that uses a top-level namespace posix may be invalid in this International Standard.

Affected subclause: 16.5.5.3
Change: Additional restrictions on macro names.
Rationale: Avoid hard to diagnose or non-portable constructs.
Effect on original feature: Names of attribute identifiers may not be used as macro names. Valid C++ 2003 code that defines override, final, carries_dependency, or noreturn as macros is invalid in this International Standard.

C.4.7 Clause 17: language support library [diff.cpp03.language.support]

Affected subclause: 17.6.2.1
Change: operator new may throw exceptions other than std::bad_alloc.
Rationale: Consistent application of noexcept.
Effect on original feature: Valid C++ 2003 code that assumes that global operator new only throws std::bad_alloc may execute differently in this International Standard. Valid C++ 2003 code that replaces the global replaceable operator new is ill-formed in this International Standard, because the exception specification of throw(std::bad_alloc) was removed.

C.4.8 Clause 19: diagnostics library [diff.cpp03.diagnostics]

Affected subclause: 19.4
Change: Thread-local error numbers.
Rationale: Support for new thread facilities.
Effect on original feature: Valid but implementation-specific C++ 2003 code that relies on errno being the same across threads may change behavior in this International Standard.
C.4.9 Clause 20: general utilities library

Affected subclause: 20.10.5
Change: Minimal support for garbage-collected regions.
Rationale: Required by new feature.
Effect on original feature: Valid C++ 2003 code, compiled without traceable pointer support, that interacts with newer C++ code using regions declared reachable may have different runtime behavior.

Change: Standard function object types no longer derived from std::unary_function or std::binary_function.
Rationale: Superseded by new feature; unary_function and binary_function are no longer defined.
Effect on original feature: Valid C++ 2003 code that depends on function object types being derived from unary_function or binary_function may fail to compile in this International Standard.

C.4.10 Clause 21: strings library

Affected subclause: 21.3
Change: basic_string requirements no longer allow reference-counted strings.
Rationale: Invalidation is subtly different with reference-counted strings. This change regularizes behavior for this International Standard.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard.

Affected subclause: 21.3.2.1
Change: Loosen basic_string invalidation rules.
Rationale: Allow small-string optimization.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. Some const member functions, such as data and c_str, no longer invalidate iterators.

C.4.11 Clause 22: containers library

Affected subclause: 22.2
Change: Complexity of size() member functions now constant.
Rationale: Lack of specification of complexity of size() resulted in divergent implementations with inconsistent performance characteristics.
Effect on original feature: Some container implementations that conform to C++ 2003 may not conform to the specified size() requirements in this International Standard. Adjusting containers such as std::list to the stricter requirements may require incompatible changes.

Affected subclause: 22.2
Change: Requirements change: relaxation.
Rationale: Clarification.
Effect on original feature: Valid C++ 2003 code that attempts to meet the specified container requirements may now be over-specified. Code that attempted to be portable across containers may need to be adjusted as follows:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Adjustment</th>
</tr>
</thead>
</table>
| (2.1) Not all containers provide | Use empty() instead of size() == 0;
| size()                          |                                   |
| (2.2) Not all containers are    |                                    |
| empty after construction        |                                    |
| (2.3) Not all containers have   |                                    |
| constant complexity for swap()  |                                    |
| (array)                         |                                    |

Affected subclause: 22.2
Change: Requirements change: default constructible.
Rationale: Clarification of container requirements.
Effect on original feature: Valid C++ 2003 code that attempts to explicitly instantiate a container using a user-defined type with no default constructor may fail to compile.

Affected subclauses: 22.2.3 and 22.2.6
Change: Signature changes: from void return types.
Rationale: Old signature threw away useful information that may be expensive to recalculate.
Effect on original feature: The following member functions have changed:

<table>
<thead>
<tr>
<th>Function</th>
<th>Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>(4.1) erase(iter) for set,</td>
<td>Removed</td>
</tr>
<tr>
<td>multiset, map, multimap</td>
<td></td>
</tr>
<tr>
<td>(4.2) erase(begin, end) for set,</td>
<td>Removed</td>
</tr>
<tr>
<td>multiset, map, multimap</td>
<td></td>
</tr>
<tr>
<td>(4.3) insert(pos, num, val) for</td>
<td>Removed</td>
</tr>
<tr>
<td>vector, deque, list, forward_list</td>
<td></td>
</tr>
<tr>
<td>(4.4) insert(pos, beg, end) for</td>
<td>Removed</td>
</tr>
<tr>
<td>vector, deque, list, forward_list</td>
<td></td>
</tr>
</tbody>
</table>
Valid C++ 2003 code that relies on these functions returning `void` (e.g., code that creates a pointer to member function that points to one of these functions) will fail to compile with this International Standard.

5 **Affected subclauses:** 22.2.3 and 22.2.6  
**Change:** Signature changes: from `iterator` to `const_iterator` parameters.  
**Rationale:** Overspecification.  
**Effect on original feature:** The signatures of the following member functions changed from taking an `iterator` to taking a `const_iterator`:

- `insert(iter, val)` for `vector`, `deque`, `list`, `set`, `multiset`, `map`, `multimap`
- `insert(pos, beg, end)` for `vector`, `deque`, `list`, `forward_list`
- `erase(begin, end)` for `set`, `multiset`, `map`, `multimap`
- all forms of `list::splice`
- all forms of `list::merge`

Valid C++ 2003 code that uses these functions may fail to compile with this International Standard.

6 **Affected subclauses:** 22.2.3 and 22.2.6  
**Change:** Signature changes: `resize`.

**Rationale:** Performance, compatibility with move semantics.  
**Effect on original feature:** For `vector`, `deque`, and `list` the fill value passed to `resize` is now passed by reference instead of by value, and an additional overload of `resize` has been added. Valid C++ 2003 code that uses this function may fail to compile with this International Standard.

### C.4.12 Clause 25: algorithms library

1 **Affected subclause:** 25.1  
**Change:** Result state of inputs after application of some algorithms.  
**Rationale:** Required by new feature.  
**Effect on original feature:** A valid C++ 2003 program may detect that an object with a valid but unspecified state has a different valid but unspecified state with this International Standard. For example, `std::remove` and `std::remove_if` may leave the tail of the input sequence with a different set of values than previously.

### C.4.13 Clause 26: numerics library

1 **Affected subclause:** 26.4  
**Change:** Specified representation of complex numbers.  
**Rationale:** Compatibility with C99.  
**Effect on original feature:** Valid C++ 2003 code that uses implementation-specific knowledge about the binary representation of the required template specializations of `std::complex` may not be compatible with this International Standard.

### C.4.14 Clause 29: input/output library

1 **Affected subclauses:** 29.7.4.1.3, 29.7.5.1.3, and 29.5.5.4  
**Change:** Specify use of `explicit` in existing boolean conversion functions.  
**Rationale:** Clarify intentions, avoid workarounds.  
**Effect on original feature:** Valid C++ 2003 code that relies on implicit boolean conversions will fail to compile with this International Standard. Such conversions occur in the following conditions:

- passing a value to a function that takes an argument of type `bool`;
- using `operator==` to compare to `false` or `true`;
- returning a value from a function with a return type of `bool`;
- initializing members of type `bool` via aggregate initialization;
- initializing a `const bool&` which would bind to a temporary object.

2 **Affected subclause:** 29.5.3.1.1  
**Change:** Change base class of `std::ios_base::failure`.  
**Rationale:** More detailed error messages.  
**Effect on original feature:** `std::ios_base::failure` is no longer derived directly from `std::exception`, but is now derived from `std::system_error`, which in turn is derived from `std::runtime_error`. Valid C++ 2003 code
that assumes that `std::ios_base::failure` is derived directly from `std::exception` may execute differently in this International Standard.

3 Affected subclause: 29.5.3
Change: Flag types in `std::ios_base` are now bitmasks with values defined as constexpr static members.
Rationale: Required for new features.

Effect on original feature: Valid C++ 2003 code that relies on `std::ios_base` flag types being represented as `std::bitset` or as an integer type may fail to compile with this International Standard. For example:

```
#include <iostream>

int main() {
    int flag = std::ios_base::hex;
    std::cout.setf(flag);  // error: setf does not take argument of type int
}
```

C.5 C++ and ISO C

This subclause lists the differences between C++ and ISO C, in addition to those listed above, by the chapters of this document.

C.5.1 Clause 5: lexical conventions

1 Affected subclause: 5.11
Change: New Keywords
New keywords are added to C++; see 5.11.
Rationale: These keywords were added in order to implement the new semantics of C++.

Effect on original feature: Change to semantics of well-defined feature. Any ISO C programs that used any of these keywords as identifiers are not valid C++ programs.

Difficulty of converting: Syntactic transformation. Converting one specific program is easy. Converting a large collection of related programs takes more work.

How widely used: Common.

2 Affected subclause: 5.13.3
Change: Type of `character-literal` is changed from `int` to `char`.
Rationale: This is needed for improved overloaded function argument type matching. For example:

```
int function( int i );
int function( char c );
```

It is preferable that this call match the second version of function rather than the first.

Effect on original feature: Change to semantics of well-defined feature. ISO C programs which depend on `sizeof('x') == sizeof(int)` will not work the same as C++ programs.

Difficulty of converting: Simple.

How widely used: Programs which depend upon `sizeof('x')` are probably rare.

3 Affected subclause: 5.13.5
Change: String literals made const.
The type of a `string-literal` is changed from "array of char" to "array of const char". The type of a UTF-8 string literal is changed from "array of char" to "array of const char8_t". The type of a UTF-16 string literal is changed from "array of some-integer-type" to "array of const char16_t". The type of a UTF-32 string literal is changed from "array of some-integer-type" to "array of const char32_t". The type of a wide string literal is changed from "array of wchar_t" to "array of const wchar_t".
Rationale: This avoids calling an inappropriate overloaded function, which might expect to be able to modify its argument.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Syntactic transformation. The fix is to add a cast:

```
char* p = "abc";  // valid in C, invalid in C++
void f(char*) {  
    char* p = (char*)"abc";  // OK: cast added
    f(p);
}
```

§ C.5.1 1617
f((char*)"def"); // OK: cast added

How widely used: Programs that have a legitimate reason to treat string literal objects as potentially modifiable memory are probably rare.

C.5.2 Clause 6: basics

1  Affected subclause: 6.2
   Change: C++ does not have “tentative definitions” as in C.
   E.g., at file scope,
   ```c
   int i;
   int i;
   ```
   is valid in C, invalid in C++. This makes it impossible to define mutually referential file-local objects with static storage duration, if initializers are restricted to the syntactic forms of C. For example,
   ```c
   struct X { int i; struct X* next; };
   static struct X a;
   static struct X b = { 0, &a };
   static struct X a = { 1, &b };
   ```
   **Rationale:** This avoids having different initialization rules for fundamental types and user-defined types.
   **Effect on original feature:** Deletion of semantically well-defined feature.
   **Difficulty of converting:** Semantic transformation. In C++, the initializer for one of a set of mutually-referential file-local objects with static storage duration must invoke a function call to achieve the initialization.
   **How widely used:** Seldom.

2  Affected subclause: 6.4
   Change: A struct is a scope in C++, not in C.
   **Rationale:** Class scope is crucial to C++, and a struct is a class.
   **Effect on original feature:** Change to semantics of well-defined feature.
   **Difficulty of converting:** Semantic transformation.
   **How widely used:** C programs use struct extremely frequently, but the change is only noticeable when struct, enumeration, or enumerator names are referred to outside the struct. The latter is probably rare.

3  Affected subclause: 6.6 [also 9.2.8]
   Change: A name of file scope that is explicitly declared const, and not explicitly declared extern, has internal linkage, while in C it would have external linkage.
   **Rationale:** Because const objects may be used as values during translation in C++, this feature urges programmers to provide an explicit initializer for each const object. This feature allows the user to put const objects in source files that are included in more than one translation unit.
   **Effect on original feature:** Change to semantics of well-defined feature.
   **Difficulty of converting:** Semantic transformation.
   **How widely used:** Seldom.

4  Affected subclause: 6.9.3.1
   Change: The main function cannot be called recursively and cannot have its address taken.
   **Rationale:** The main function may require special actions.
   **Effect on original feature:** Deletion of semantically well-defined feature.
   **Difficulty of converting:** Trivial: create an intermediary function such as mymain(argc, argv).
   **How widely used:** Seldom.

5  Affected subclause: 6.8
   Change: C allows "compatible types" in several places, C++ does not.
   For example, otherwise-identical struct types with different tag names are “compatible” in C but are distinctly different types in C++.
   **Rationale:** Stricter type checking is essential for C++.
   **Effect on original feature:** Deletion of semantically well-defined feature.
   **Difficulty of converting:** Semantic transformation. The "typesafe linkage" mechanism will find many, but not all, of such problems. Those problems not found by typesafe linkage will continue to function properly, according to the
“layout compatibility rules” of this document.

How widely used: Common.

C.5.3 Clause 7: expressions

1 Affected subclause: 7.3.11
Change: Converting void* to a pointer-to-object type requires casting.

```c
char a[10];
void* b = a;
void foo() {
    char* c = b;
}
```

ISO C will accept this usage of pointer to void being assigned to a pointer to object type. C++ will not.

Rationale: C++ tries harder than C to enforce compile-time type safety.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Could be automated. Violations will be diagnosed by the C++ translator. The fix is to add a cast. For example:

```c
char* c = (char*) b;
```

How widely used: This is fairly widely used but it is good programming practice to add the cast when assigning pointer-to-void to pointer-to-object. Some ISO C translators will give a warning if the cast is not used.

2 Affected subclause: 7.6.1.2
Change: Implicit declaration of functions is not allowed.

Rationale: The type-safe nature of C++.

Effect on original feature: Deletion of semantically well-defined feature. Note: the original feature was labeled as "obsolescent" in ISO C.

Difficulty of converting: Syntactic transformation. Facilities for producing explicit function declarations are fairly widespread commercially.

How widely used: Common.

3 Affected subclauses: 7.6.1.5 and 7.6.2.2
Change: Decrement operator is not allowed with bool operand.

Rationale: Feature with surprising semantics.

Effect on original feature: A valid ISO C expression utilizing the decrement operator on a bool lvalue (for instance, via the C typedef in <stdbool.h> (D.9.4)) is ill-formed in this International Standard.

4 Affected subclauses: 7.6.2.4 and 7.6.3
Change: Types must be defined in declarations, not in expressions.

In C, a sizeof expression or cast expression may define a new type. For example,

```c
p = (void*)(struct x {int i;}) 0;
```

defines a new type, struct x.

Rationale: This prohibition helps to clarify the location of definitions in the source code.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

5 Affected subclauses: 7.6.16, 7.6.19, and 7.6.20
Change: The result of a conditional expression, an assignment expression, or a comma expression may be an lvalue.

Rationale: C++ is an object-oriented language, placing relatively more emphasis on lvalues. For example, function calls may yield lvalues.

Effect on original feature: Change to semantics of well-defined feature. Some C expressions that implicitly rely on lvalue-to-rvalue conversions will yield different results. For example,

```c
char arr[100];
sizeof(0, arr)
```

yields 100 in C++ and sizeof(char*) in C.

Difficulty of converting: Programs must add explicit casts to the appropriate rvalue.

How widely used: Rare.
C.5.4 Clause 8: statements

1 Affected subclauses: 8.5.2 and 8.7.5

Change: It is now invalid to jump past a declaration with explicit or implicit initializer (except across entire block not entered).

Rationale: Constructors used in initializers may allocate resources which need to be de-allocated upon leaving the block. Allowing jump past initializers would require complicated runtime determination of allocation. Furthermore, any use of the uninitialized object could be a disaster. With this simple compile-time rule, C++ assures that if an initialized variable is in scope, then it has assuredly been initialized.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Seldom.

2 Affected subclause: 8.7.3

Change: It is now invalid to return (explicitly or implicitly) from a function which is declared to return a value without actually returning a value.

Rationale: The caller and callee may assume fairly elaborate return-value mechanisms for the return of class objects. If some flow paths execute a return without specifying any value, the implementation must embody many more complications. Besides, promising to return a value of a given type, and then not returning such a value, has always been recognized to be a questionable practice, tolerated only because very-old C had no distinction between void functions and int functions.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. Add an appropriate return value to the source code, such as zero.

How widely used: Seldom. For several years, many existing C implementations have produced warnings in this case.

C.5.5 Clause 9: declarations

1 Affected subclause: 9.2.1

Change: In C++, the static or extern specifiers can only be applied to names of objects or functions. Using these specifiers with type declarations is illegal in C++. In C, these specifiers are ignored when used on type declarations.

Example:

static struct S { // valid C, invalid in C++
    int i;
};

Rationale: Storage class specifiers don’t have any meaning when associated with a type. In C++, class members can be declared with the static storage class specifier. Allowing storage class specifiers on type declarations could render the code confusing for users.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

2 Affected subclause: 9.2.1

Change: In C++, register is not a storage class specifier.

Rationale: The storage class specifier had no effect in C++.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Common.

3 Affected subclause: 9.2.3

Change: A C++ typedef name must be different from any class type name declared in the same scope (except if the typedef is a synonym of the class name with the same name). In C, a typedef name and a struct tag name declared in the same scope can have the same name (because they have different name spaces).

Example:

typedef struct name1 { /* ... */ } name1; // valid C and C++
struct name { /* ... */ }; // valid C and C++
typedef int name; // valid C, invalid C++
**Rationale:** For ease of use, C++ doesn’t require that a type name be prefixed with the keywords `class`, `struct` or `union` when used in object declarations or type casts.

Example:

```cpp
class name { /* ... */ }
name i; // i has type class name
```

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. One of the 2 types has to be renamed.

**How widely used:** Seldom.

4 **Affected subclause:** 9.2.8 [see also 6.6]

**Change:** Const objects must be initialized in C++ but can be left uninitialized in C.

**Rationale:** A const object cannot be assigned to so it must be initialized to hold a useful value.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation.

**How widely used:** Seldom.

5 **Affected subclause:** 9.2.8

**Change:** Banning implicit int.

In C++, a `decl-specifier-seq` must contain a `type-specifier`, unless it is followed by a declarator for a constructor, a destructor, or a conversion function. In the following example, the left-hand column presents valid C; the right-hand column presents equivalent C++:

```cpp
void f(const parm); void f(const int parm);
const n = 3; const int n = 3;
main() int main()
/* ... */ /* ... */
```

**Rationale:** In C++, implicit int creates several opportunities for ambiguity between expressions involving function-like casts and declarations. Explicit declaration is increasingly considered to be proper style. Liaison with WG14 (C) indicated support for (at least) deprecating implicit int in the next revision of C.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation. Could be automated.

**How widely used:** Common.

6 **Affected subclause:** 9.2.8.5

**Change:** The keyword `auto` cannot be used as a storage class specifier.

```cpp
void f()
{
    auto int x; // valid C, invalid C++
}
```

**Rationale:** Allowing the use of `auto` to deduce the type of a variable from its initializer results in undesired interpretations of `auto` as a storage class specifier in certain contexts.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Rare.

7 **Affected subclause:** 9.3.3.5

**Change:** In C++, a function declared with an empty parameter list takes no arguments. In C, an empty parameter list means that the number and type of the function arguments are unknown.

Example:

```cpp
int f(); // means int f(void) in C++
// int f( unknown ) in C
```

**Rationale:** This is to avoid erroneous function calls (i.e., function calls with the wrong number or type of arguments).

**Effect on original feature:** Change to semantics of well-defined feature. This feature was marked as “obsolete” in C.

**Difficulty of converting:** Syntactic transformation. The function declarations using C incomplete declaration style
must be completed to become full prototype declarations. A program may need to be updated further if different calls to the same (non-prototype) function have different numbers of arguments or if the type of corresponding arguments differed.

**How widely used:** Common.

**Affected subclause:** 9.3.3.5 [see 7.6.2.4]

**Change:** In C++, types may not be defined in return or parameter types. In C, these type definitions are allowed.

**Example:**
```c
void f( struct S { int a; } arg ) {} // valid C, invalid C++
enum E { A, B, C } f() {} // valid C, invalid C++
```

**Rationale:** When comparing types in different translation units, C++ relies on name equivalence when C relies on structural equivalence. Regarding parameter types: since the type defined in a parameter list would be in the scope of the function, the only legal calls in C++ would be from within the function itself.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. The type definitions must be moved to file scope, or in header files.

**How widely used:** Seldom. This style of type definition is seen as poor coding style.

---

**Affected subclause:** 9.5

**Change:** In C++, the syntax for function definition excludes the "old-style" C function. In C, "old-style" syntax is allowed, but deprecated as "obsolescent".

**Rationale:** Prototypes are essential to type safety.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Common in old programs, but already known to be obsolescent.

---

**Affected subclause:** 9.4.1

**Change:** In C++, designated initialization support is restricted compared to the corresponding functionality in C. In C++, designators for non-static data members must be specified in declaration order, designators for array elements and nested designators are not supported, and designated and non-designated initializers cannot be mixed in the same initializer list.

**Example:**
```c
struct A { int x, y; };
struct B { struct A a; };
struct A a = {.y = 1, .x = 2}; // valid C, invalid C++
int arr[3] = {{1}, 5}; // valid C, invalid C++
struct B b = {.a.x = 0}; // valid C, invalid C++
struct A c = {.x = 1, 2}; // valid C, invalid C++
```

**Rationale:** In C++, members are destroyed in reverse construction order and the elements of an initializer list are evaluated in lexical order, so field initializers must be specified in order. Array designators conflict with lambda-expression syntax. Nested designators are seldom used.

**Effect on original feature:** Deletion of feature that is incompatible with C++.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Out-of-order initializers are common. The other features are seldom used.

---

**Affected subclause:** 9.4.2

**Change:** In C++, when initializing an array of character with a string, the number of characters in the string (including the terminating '\0') must not exceed the number of elements in the array. In C, an array can be initialized with a string even if the array is not large enough to contain the string-terminating '\0'.

**Example:**
```c
char array[4] = "abcd"; // valid C, invalid C++
```

**Rationale:** When these non-terminated arrays are manipulated by standard string functions, there is potential for major catastrophe.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. The arrays must be declared one element bigger to contain the
string terminating ‘\0’.

**How widely used:** Seldom. This style of array initialization is seen as poor coding style.

**Affected subclause:** 9.7.1

**Change:** C++ objects of enumeration type can only be assigned values of the same enumeration type. In C, objects of enumeration type can be assigned values of any integral type.

Example:

```c
enum color { red, blue, green }
enum color c = 1;    // valid C, invalid C++
```

**Rationale:** The type-safe nature of C++.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation. (The type error produced by the assignment can be automatically corrected by applying an explicit cast.)

**How widely used:** Common.

---

**Affected subclause:** 9.7.1

**Change:** In C++, the type of an enumerator is its enumeration. In C, the type of an enumerator is int.

Example:

```c
enum e { A }
sizeof(A) == sizeof(int)    // in C
sizeof(A) == sizeof(e)     // in C++
/* and sizeof(int) is not necessarily equal to sizeof(e) */
```

**Rationale:** In C++, an enumeration is a distinct type.

**Effect on original feature:** Change to semantics of well-defined feature.

**Difficulty of converting:** Semantic transformation.

**How widely used:** Seldom. The only time this affects existing C code is when the size of an enumerator is taken. Taking the size of an enumerator is not a common C coding practice.

---

**C.5.6 Clause 11: classes**

**Affected subclause:** 11.3 [see also 9.2.3]

**Change:** In C++, a class declaration introduces the class name into the scope where it is declared and hides any object, function or other declaration of that name in an enclosing scope. In C, an inner scope declaration of a struct tag name never hides the name of an object or function in an outer scope.

Example:

```c
int x[99];
void f() {
    struct x { int a; }
    sizeof(x);    // size of the array in C
    /* size of the struct in C++ */
}
```

**Rationale:** This is one of the few incompatibilities between C and C++ that can be attributed to the new C++ name space definition where a name can be declared as a type and as a non-type in a single scope causing the non-type name to hide the type name and requiring that the keywords class, struct, union or enum be used to refer to the type name. This new name space definition provides important notational conveniences to C++ programmers and helps making the use of the user-defined types as similar as possible to the use of fundamental types. The advantages of the new name space definition were judged to outweigh by far the incompatibility with C described above.

**Effect on original feature:** Change to semantics of well-defined feature.

**Difficulty of converting:** Semantic transformation. If the hidden name that needs to be accessed is at global scope, the :: C++ operator can be used. If the hidden name is at block scope, either the type or the struct tag has to be renamed.

**How widely used:** Seldom.

---

**Affected subclause:** 11.4.4.2

**Change:** Copying volatile objects.
The implicitly-declared copy constructor and implicitly-declared copy assignment operator cannot make a copy of a volatile lvalue. For example, the following is valid in ISO C:

```c
struct X { int i; };
volatile struct X x1 = {0};
struct X x2 = x1; // invalid C++
struct X x3;
```

Rationale: Several alternatives were debated at length. Changing the parameter to `volatile const X&` would greatly complicate the generation of efficient code for class objects. Discussion of providing two alternative signatures for these implicitly-defined operations raised unanswered concerns about creating ambiguities and complicating the rules that specify the formation of these operators according to the bases and members.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. If volatile semantics are required for the copy, a user-declared constructor or assignment must be provided. If non-volatile semantics are required, an explicit `const_cast` can be used.

How widely used: Seldom.

Affected subclause: 11.4.9

Change: Bit-fields of type plain `int` are signed.

Rationale: Leaving the choice of signedness to implementations could lead to inconsistent definitions of template specializations. For consistency, the implementation freedom was eliminated for non-dependent types, too.

Effect on original feature: The choice is implementation-defined in C, but not so in C++.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

Affected subclause: 11.4.10

Change: In C++, the name of a nested class is local to its enclosing class. In C the name of the nested class belongs to the same scope as the name of the outermost enclosing class.

Example:

```c
struct X {
    struct Y { /* ... */ } y;
};
struct Y yy; // valid C, invalid C++
```

Rationale: C++ classes have member functions which require that classes establish scopes. The C rule would leave classes as an incomplete scope mechanism which would prevent C++ programmers from maintaining locality within a class. A coherent set of scope rules for C++ based on the C rule would be very complicated and C++ programmers would be unable to predict reliably the meanings of nontrivial examples involving nested or local functions.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation. To make the struct type name visible in the scope of the enclosing struct, the struct tag could be declared in the scope of the enclosing struct, before the enclosing struct is defined. Example:

```c
struct Y; // struct Y and struct X are at the same scope
struct X {
    struct Y { /* ... */ } y;
};
```

All the definitions of C struct types enclosed in other struct definitions and accessed outside the scope of the enclosing struct could be exported to the scope of the enclosing struct. Note: this is a consequence of the difference in scope rules, which is documented in 6.4.

How widely used: Seldom.

Affected subclause: 11.4.11

Change: In C++, a typedef name may not be redeclared in a class definition after being used in that definition.

Example:

```c
typedef int I;
struct S {
    I i;
}
```
Rationale: When classes become complicated, allowing such a redefinition after the type has been used can create confusion for C++ programmers as to what the meaning of I really is.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. Either the type or the struct member has to be renamed.

How widely used: Seldom.

C.5.7 Clause 15: preprocessing directives

Affected subclause: 15.11

Change: Whether __STDC__ is defined and if so, what its value is, are implementation-defined.

Rationale: C++ is not identical to ISO C. Mandating that __STDC__ be defined would require that translators make an incorrect claim. Each implementation must choose the behavior that will be most useful to its marketplace.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Programs and headers that reference __STDC__ are quite common.

C.6 C standard library

This subclause summarizes the explicit changes in headers, definitions, declarations, or behavior between the C standard library in the C standard and the parts of the C++ standard library that were included from the C standard library.

C.6.1 Modifications to headers

1. For compatibility with the C standard library, the C++ standard library provides the C headers enumerated in D.9, but their use is deprecated in C++.

2. There are no C++ headers for the C standard library's headers <stdatomic.h>, <stdnoreturn.h>, and <threads.h>, nor are these headers from the C standard library headers themselves part of C++.

3. The C headers <complex.h> and <tgmath.h> do not contain any of the content from the C standard library and instead merely include other headers from the C++ standard library.

C.6.2 Modifications to definitions

C.6.2.1 Types char16_t and char32_t

The types char16_t and char32_t are distinct types rather than typedefs to existing integral types. The tokens char16_t and char32_t are keywords in this International Standard (5.11). They do not appear as macro or type names defined in <uchar> (21.5.5).

C.6.2.2 Type wchar_t

The type wchar_t is a distinct type rather than a typedef to an existing integral type. The token wchar_t is a keyword in this International Standard (5.11). It does not appear as a macro or type name defined in any of <cassert> (19.3.1), <cstddef> (17.2.1), or <cwchar> (21.5.4).

C.6.2.3 Header <assert.h>

The token static_assert is a keyword in this International Standard (5.11). It does not appear as a macro name defined in <assert> (19.3.1).

C.6.2.4 Header <iso646.h>

The tokens and, and_eq, bitand, bitor, compl, not, not_eq, or, or_eq, xor, and xor_eq are keywords in this International Standard (5.11), and are not introduced as macros by <iso646.h> (D.9.2).

C.6.2.5 Header <stdalign.h>

The token alignas is a keyword in this International Standard (5.11), and is not introduced as a macro by <stdalign.h> (D.9.3).

C.6.2.6 Header <stdbool.h>

The tokens bool, true, and false are keywords in this International Standard (5.11), and are not introduced as macros by <stdbool.h> (D.9.4).

§ C.6.2.6
C.6.2.7 Macro NULL

1 The macro NULL, defined in any of <locale> (28.5.1), <cstdlib> (17.2.1), <stdio> (29.12.1), <stdlib> (17.2.2), <string> (21.5.3), <ctime> (27.14), or <wchar> (21.5.4), is an implementation-defined C++ null pointer constant in this International Standard (17.2).

C.6.3 Modifications to declarations

1 Header <cstring> (21.5.3): The following functions have different declarations:

(1.1) — strchr
(1.2) — strpbrk
(1.3) — strrchr
(1.4) — strstr
(1.5) — memchr

Subclause 21.5.3 describes the changes.

2 Header <cwchar> (21.5.4): The following functions have different declarations:

(2.1) — wcschr
(2.2) — wcspbrk
(2.3) — wcsrchr
(2.4) — wcsstr
(2.5) — wmemchr

Subclause 21.5.4 describes the changes.

3 Header <cstdlib> (17.2.1) declares the name nullptr_t in addition to the names declared in <stddef.h> (D.9) in the C standard library.

C.6.4 Modifications to behavior

1 Header <cstdlib> (17.2.2): The following functions have different behavior:

(1.1) — atexit
(1.2) — exit
(1.3) — abort

Subclause 17.5 describes the changes.

2 Header <csetjmp> (17.13.2): The following functions have different behavior:

(2.1) — longjmp

Subclause 17.13.2 describes the changes.

C.6.4.1 Macro offsetof(type, member-designator)

1 The macro offsetof, defined in <cstdlib> (17.2.1), accepts a restricted set of type arguments in this International Standard. Subclause 17.2.4 describes the change.

C.6.4.2 Memory allocation functions

1 The functions aligned_alloc, calloc, malloc, and realloc are restricted in this International Standard. Subclause 20.10.12 describes the changes.
Annex D  (normative)
Compatibility features  [depr]

1 This Clause describes features of the C++ Standard that are specified for compatibility with existing implementations.
2 These are deprecated features, where deprecated is defined as: Normative for the current edition of this International Standard, but having been identified as a candidate for removal from future revisions. An implementation may declare library names and entities described in this Clause with the deprecated attribute (9.12.4).

D.1 Arithmetic conversion on enumerations  [depr.arith.conv.enum]
1 The ability to apply the usual arithmetic conversions (7.4) on operands where one is of enumeration type and the other is of a different enumeration type or a floating-point type is deprecated. [Note: Three-way comparisons (7.6.8) between such operands are ill-formed. — end note]  [Example:

```cpp
enum E1 { e);
enum E2 { f ,};
bool b = e <= 3.7;  // deprecated
int k = f - e;  // deprecated
auto cmp = e <=> f;  // error
```
— end example]

D.2 Implicit capture of *this by reference  [depr.capture.this]
1 For compatibility with prior C++ International Standards, a lambda-expression with capture-default = (7.5.5.2) may implicitly capture *this by reference. [Example:

```cpp
struct X {
    int x ;
    void foo(int n) {
        auto f = [=]() { x = n; };  // deprecated: x means this->x, not a copy thereof
        auto g = [=, this] () { x = n; };  // recommended replacement
    }
};
```
— end example]

D.3 Comma operator in subscript expressions  [depr.comma.subscript]
1 A comma expression (7.6.20) appearing as the expr-or-braced-init-list of a subscripting expression (7.6.1.1) is deprecated. [Note: A parenthesized comma expression is not deprecated. — end note]  [Example:

```cpp
void f(int *a, int b, int c) {
    a[b,c];  // deprecated
    a[(b,c)];  // OK
}
```
— end example]

D.4 Array comparisons  [depr.array.comp]
1 Equality and relational comparisons (7.6.10, 7.6.9) between two operands of array type are deprecated. [Note: Three-way comparisons (7.6.8) between such operands are ill-formed. — end note]  [Example:

```cpp
int arr1[5];
int arr2[5];
bool same = arr1 == arr2;  // deprecated, same as &arr1[0] == &arr2[0],
// does not compare array contents
auto cmp = arr1 <=> arr2;  // error
```
— end example]
D.5 Deprecated volatile types

1 Postfix ++ and -- expressions (7.6.1.5) and prefix ++ and -- expressions (7.6.2.2) of volatile-qualified arithmetic and pointer types are deprecated.

[Example:
volatile int velociraptor;
++velociraptor;     // deprecated
— end example]

2 Certain assignments where the left operand is a volatile-qualified non-class type are deprecated; see 7.6.19.

[Example:
int neck, tail;
volatile int brachiosaur;
brachiosaur = neck;       // OK
tail = brachiosaur;       // OK
tail = brachiosaur = neck; // deprecated
brachiosaur += neck;      // deprecated
brachiosaur = brachiosaur + neck; // OK
— end example]

3 A function type (9.3.3.5) with a parameter with volatile-qualified type or with a volatile-qualified return type is deprecated.

[Example:
volatile struct amber jurassic();             // deprecated
void trex(volatile short left_arm, volatile short right_arm); // deprecated
void fly(volatile struct pterosaur* pteranodon);       // OK
— end example]

4 A structured binding (9.6) of a volatile-qualified type is deprecated.

[Example:
struct linhenykus { short forelimb; };
void park(linhenykus alvarezsauroid) {
    volatile auto [what_is_this] = alvarezsauroid;   // deprecated
    // ...
}
— end example]

D.6 Redefinition of static constexpr data members

1 For compatibility with prior C++ International Standards, a constexpr static data member may be redundantly redeclared outside the class with no initializer. This usage is deprecated. [Example:
struct A {
    static constexpr int n = 5;    // definition (declaration in C++ 2014)
};
constexpr int A::n;           // redundant declaration (definition in C++ 2014)
— end example]

D.7 Non-local use of TU-local entities

1 A declaration of a non-TU-local entity that is an exposure (6.6) is deprecated. [Note: Such a declaration in an importable module unit is ill-formed. — end note] [Example:
namespace {
    struct A {
        void f() {}
    };
}
A h();                        // deprecated: not internal linkage
inline void g() {A().f();}   // deprecated: inline and not internal linkage
— end example]
D.8 Implicit declaration of copy functions

The implicit definition of a copy constructor (11.4.4.2) as defaulted is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor (11.4.6). The implicit definition of a copy assignment operator (11.4.5) as defaulted is deprecated if the class has a user-declared copy constructor or a user-declared destructor. In a future revision of this International Standard, these implicit definitions could become deleted (9.5.3).

D.9 C headers

For compatibility with the C standard library, the C++ standard library provides the C headers shown in Table 147.

Table 147: C headers

| <assert.h> | <inttypes.h> | <signal.h> | <stdio.h> | <wchar.h> |
| <complex.h> | <iso646.h> | <stdalign.h> | <stdlib.h> | <wctype.h> |
| <ctype.h> | <limits.h> | <stdarg.h> | <string.h> | |
| <errno.h> | <locale.h> | <stdbool.h> | <time.h> | |
| <float.h> | <setjmp.h> | <stdint.h> | <uchar.h> | |

D.9.1 Header <complex.h> synopsis

#include <complex>

The header <complex.h> behaves as if it simply includes the header <complex> (26.4.1).

D.9.2 Header <iso646.h> synopsis

The C++ header <iso646.h> is empty. [Note: and, and_eq, bitand, bitor, compl, not_eq, not, or, or_eq, xor, and xor_eq are keywords in this International Standard (5.11). — end note]

D.9.3 Header <stdalign.h> synopsis

#define __alignas_is_defined 1

The contents of the C++ header <stdalign.h> are the same as the C standard library header <stdalign.h>, with the following changes: The header <stdalign.h> does not define a macro named alignas.

See also: ISO C 7.15

D.9.4 Header <stdbool.h> synopsis

#define __bool_true_false_are_defined 1

The contents of the C++ header <stdbool.h> are the same as the C standard library header <stdbool.h>, with the following changes: The header <stdbool.h> does not define macros named bool, true, or false.

See also: ISO C 7.18

D.9.5 Header <tgmath.h> synopsis

#include <cmath>
#include <complex>

The header <tgmath.h> behaves as if it simply includes the headers <cmath> (26.8.1) and <complex> (26.4.1).

[Note: The overloads provided in C by type-generic macros are already provided in <complex> and <cmath> by “sufficient” additional overloads. — end note]

[Note: Names introduced by <cmath> or <complex> in namespace std are not placed into the global namespace scope by <tgmath.h>. — end note]
D.9.6 Other C headers

1 Every C header other than `<complex.h>` (D.9.1), `<iso646.h>` (D.9.2), `<stdbool.h>` (D.9.4), and `<tgmath.h>` (D.9.5), each of which has a name of the form `<name>.h`, behaves as if each name placed in the standard library namespace by the corresponding `<name>` header is placed within the global namespace scope, except for the functions described in 26.8.6, the declaration of std::byte (17.2.1), and the functions and function templates described in 17.2.5. It is unspecified whether these names are first declared or defined within namespace scope (6.4.6) of the namespace std and are then injected into the global namespace scope by explicit using-declarations (9.9).

2 [Example: The header `<cstdlib>` assuredly provides its declarations and definitions within the namespace std. It may also provide these names within the global namespace. The header `<stdlib.h>` assuredly provides the same declarations and definitions within the global namespace, much as in the C Standard. It may also provide these names within the namespace std. — end example]

D.10 Requires paragraph

1 In addition to the elements specified in 16.4.1.4, descriptions of function semantics may also contain a Requires: element to denote the preconditions for calling a function.

2 Violation of any preconditions specified in a function’s Requires: element results in undefined behavior unless the function’s Throws: element specifies throwing an exception when the precondition is violated.

D.11 Relational operators

1 The header `<utility>` (20.2.1) has the following additions:

   namespace std::rel_ops {
      template<class T> bool operator!=(const T&, const T&);
      template<class T> bool operator> (const T&, const T&);
      template<class T> bool operator<=(const T&, const T&);
      template<class T> bool operator>=(const T&, const T&);
   }

2 To avoid redundant definitions of `operator!=` out of `operator==` and operators `>`, `<=` and `>=` out of `operator<`, the library provides the following:

   template<class T> bool operator!=(const T& x, const T& y);

3 Requires: Type T is Cpp17EqualityComparable (Table 25).

4 Returns: !(x == y).

   template<class T> bool operator>(const T& x, const T& y);

5 Requires: Type T is Cpp17LessThanComparable (Table 26).

6 Returns: y < x.

   template<class T> bool operator<=(const T& x, const T& y);

7 Requires: Type T is Cpp17LessThanComparable (Table 26).

8 Returns: !(y < x).

   template<class T> bool operator>=(const T& x, const T& y);

9 Requires: Type T is Cpp17LessThanComparable (Table 26).

10 Returns: !(x < y).

D.12 char* streams

D.12.1 Header `<strstream>` synopsis

1 The header `<strstream>` defines types that associate stream buffers with character array objects and assist reading and writing such objects.

   namespace std {
      class strstreambuf;
      class istrstream;
      class ostrstream;
      class strstream;
   }
The class `strstreambuf` associates the input sequence, and possibly the output sequence, with an object of some character array type, whose elements store arbitrary values. The array object has several attributes.

1 [Note: For the sake of exposition, these are represented as elements of a bitmask type (indicated here as T1) called `strstate`. The elements are:

   - allocated, set when a dynamic array object has been allocated, and hence should be freed by the destructor for the `strstreambuf` object;
   - constant, set when the array object has `const` elements, so the output sequence cannot be written;
   - dynamic, set when the array object is allocated (or reallocated) as necessary to hold a character sequence that can change in length;
   - frozen, set when the program has requested that the array object not be altered, reallocated, or freed.

   — end note]

2 [Note: For the sake of exposition, the maintained data is presented here as:

   - `strstate strmode`, the attributes of the array object associated with the `strstreambuf` object;]
— int alsize, the suggested minimum size for a dynamic array object;
— void* (*palloc)(size_t), points to the function to call to allocate a dynamic array object;
— void (*pfree)(void*), points to the function to call to free a dynamic array object.

— end note]

4 Each object of class strstreambuf has a seekable area, delimited by the pointers seeklow and seekhigh. If gnext is a null pointer, the seekable area is undefined. Otherwise, seeklow equals gbeg and seekhigh is either pend, if pend is not a null pointer, or gend.

D.12.2.1 strstreambuf constructors

[depr.strstreambuf.cons]
explicit strstreambuf(streamsize alsize_arg);

Effects: Initializes the base class with streambuf(). The postconditions of this function are indicated in

Table 148: strstreambuf(streamsize) effects [tab:depr.strstreambuf.cons.sz]

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>dynamic</td>
</tr>
<tr>
<td>alsize</td>
<td>alsize_arg</td>
</tr>
<tr>
<td>palloc</td>
<td>a null pointer</td>
</tr>
<tr>
<td>pfree</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));

Effects: Initializes the base class with streambuf(). The postconditions of this function are indicated in

Table 149: strstreambuf(void* (*)(size_t), void (*)(void*)) effects [tab:depr.strstreambuf.cons.alloc]

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>dynamic</td>
</tr>
<tr>
<td>alsize</td>
<td>an unspecified value</td>
</tr>
<tr>
<td>palloc</td>
<td>palloc_arg</td>
</tr>
<tr>
<td>pfree</td>
<td>pfree_arg</td>
</tr>
</tbody>
</table>

strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = nullptr);
strstreambuf(signed char* gnext_arg, streamsize n,
            signed char* pbeg_arg = nullptr);
strstreambuf(unsigned char* gnext_arg, streamsize n,
              unsigned char* pbeg_arg = nullptr);

Effects: Initializes the base class with streambuf(). The postconditions of this function are indicated in

Table 150: strstreambuf(charT*, streamsize, charT*) effects [tab:depr.strstreambuf.cons.ptr]

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>0</td>
</tr>
<tr>
<td>alsize</td>
<td>an unspecified value</td>
</tr>
<tr>
<td>palloc</td>
<td>a null pointer</td>
</tr>
<tr>
<td>pfree</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

4 gnext_arg shall point to the first element of an array object whose number of elements N is determined as follows:

— If n > 0, N is n.
— If n == 0, N is std::strlen(gnext_arg).
© ISO/IEC

Dxxxx

---

4.3

- If \( n < 0 \), \( N \) is INT_MAX.\(^{327}\)

5

If \( \text{pbeg}\_\text{arg} \) is a null pointer, the function executes:

\[
\text{setg} \left( \text{gnext}\_\text{arg}, \text{gnext}\_\text{arg}, \text{gnext}\_\text{arg} + N \right);
\]

Otherwise, the function executes:

\[
\text{setg} \left( \text{gnext}\_\text{arg}, \text{gnext}\_\text{arg}, \text{pbeg}\_\text{arg} \right);
\]

\[
\text{setp} \left( \text{pbeg}\_\text{arg}, \text{pbeg}\_\text{arg} + N \right);
\]

\[
\text{strstreambuf} \left( \text{const char}\* \text{gnext}\_\text{arg}, \text{streamsize} \ n \right);
\]

\[
\text{strstreambuf} \left( \text{const signed char}\* \text{gnext}\_\text{arg}, \text{streamsize} \ n \right);
\]

\[
\text{strstreambuf} \left( \text{const unsigned char}\* \text{gnext}\_\text{arg}, \text{streamsize} \ n \right);
\]

Effects: Behaves the same as \text{strstreambuf}((\text{char}* \text{gnext}\_\text{arg}, \text{n}), except that the constructor also sets constant in \text{strmode}.

virtual ~strstreambuf();

Effects: Destroys an object of class strstreambuf. The function frees the dynamically allocated array object only if (\text{strmode} & \text{allocated}) != 0 and (\text{strmode} & \text{frozen}) == 0. (D.12.2.3 describes how a dynamically allocated array object is freed.)

D.12.2.2 Member functions

[depr.strstreambuf.members]

void freeze(bool\ freezefl = true);

Effects: If \text{strmode} & \text{dynamic} is nonzero, alters the freeze status of the dynamic array object as follows:

\[\text{(1.1)} \quad \text{If freezefl is true, the function sets frozen in strmode.} \]

\[\text{(1.2)} \quad \text{Otherwise, it clears frozen in strmode.} \]

char* str();

Effects: Calls freeze(), then returns the beginning pointer for the input sequence, gbeg.

Remarks: The return value can be a null pointer.

int pcount() const;

Effects: If the next pointer for the output sequence, pnext, is a null pointer, returns zero. Otherwise, returns the current effective length of the array object as the next pointer minus the beginning pointer for the output sequence, pnext - pbeg.

D.12.2.3 strstreambuf overridden virtual functions

[depr.strstreambuf.virtuals]

int\_type\ overflow\(\text{int\_type} c = \text{EOF}\) override;

Effects: Appends the character designated by \( c \) to the output sequence, if possible, in one of two ways:

\[\text{(1.1)} \quad \text{If} \ c \text{ !=} \text{EOF} \text{and if either the output sequence has a write position available or the function makes a write position available (as described below), assigns} \ c \text{to } \ast\text{pnext++}. \]

\[\text{Returns}\ (\text{unsigned}\ \text{char})c. \]

\[\text{(1.2)} \quad \text{If} \ c \text{ ==}\ \text{EOF} \text{, there is no character to append.} \]

\[\text{Returns a value other than EOF.} \]

Remarks: The function can alter the number of write positions available as a result of any call.

To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements \( n \) to hold the current array object (if any), plus at least one additional write position. How many additional write positions are made available is otherwise unspecified.\(^{328}\) If \text{malloc} is not a null pointer, the function calls \((\text{*malloc})(n)\) to allocate the new dynamic array object. Otherwise, it evaluates the expression \text{new} char\_T[n]. In either case, if the allocation fails, the function returns EOF. Otherwise, it sets allocated in strmode.

---

\(^{327}\) The function signature \text{strlen(const char*)} is declared in \text{<cstring> (21.5.3). The macro INT_MAX is defined in <climits> (17.3.6).}

\(^{328}\) An implementation should consider \text{alsize} in making this decision.
To free a previously existing dynamic array object whose first element address is \( p \): If \( \text{pfree} \) is not a null pointer, the function calls \((\text{pfree})(p)\). Otherwise, it evaluates the expression \( \text{delete}[]p \).

If \((\text{strmode} \& \text{dynamic}) == 0\), or if \((\text{strmode} \& \text{frozen}) != 0\), the function cannot extend the array (reallocate it with greater length) to make a write position available.

\[
\text{int\_type \text{pbackfail}(int\_type c = EOF) override;}
\]

Puts back the character designated by \( c \) to the input sequence, if possible, in one of three ways:

- If \( c != \text{EOF} \), if the input sequence has a putback position available, and if \((\text{char})c == \text{gnext}[-1]\), assigns \( \text{gnext} - 1 \) to \( \text{gnext} \). Returns \( c \).
- If \( c != \text{EOF} \), if the input sequence has a putback position available, and if \( \text{strmode} \& \text{constant} \) is zero, assigns \( c \) to \( \ast \text{--gnext} \). Returns \( c \).
- If \( c == \text{EOF} \) and if the input sequence has a putback position available, assigns \( \text{gnext} - 1 \) to \( \text{gnext} \). Returns a value other than \( \text{EOF} \).

Returns \( \text{EOF} \) to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

\[
\text{int\_type \text{underflow}() override;}
\]

Effects: Reads a character from the input sequence, if possible, without moving the stream position past it, as follows:

- If the input sequence has a read position available, the function signals success by returning \((\text{unsigned char})\ast\text{gnext}\).
- Otherwise, if the current write next pointer \( \text{pnext} \) is not a null pointer and is greater than the current read end pointer \( \text{gend} \), makes a read position available by assigning to \( \text{gend} \) a value greater than \( \text{gnext} \) and no greater than \( \text{pnext} \). Returns \((\text{unsigned char})\ast\text{gnext}\).

Returns \( \text{EOF} \) to indicate failure.

Remarks: The function can alter the number of read positions available as a result of any call.

\[
\text{pos\_type \text{seekoff}(off\_type off, seekdir way, openmode which = in | out) override;}
\]

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 151.

Table 151: \text{seekoff} positioning

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>((\text{which} &amp; \text{ios::in}) != 0)</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>((\text{which} &amp; \text{ios::out}) != 0)</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>((\text{which} &amp; (\text{ios::in}</td>
<td>\text{ios::out})) == (\text{ios::in}</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines \( \text{newoff} \) as indicated in Table 152.

If \((\text{newoff} + \text{off}) < (\text{seeklow} - \text{xbeg})\) or \((\text{seekhigh} - \text{xbeg}) < (\text{newoff} + \text{off})\), the positioning operation fails. Otherwise, the function assigns \( \text{xbeg} + \text{newoff} + \text{off} \) to the next pointer \( \text{xnext} \).

Returns: \( \text{pos\_type}(\text{newoff}) \), constructed from the resultant offset \( \text{newoff} \) (of type \( \text{off\_type} \)), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is \( \text{pos\_type}(\text{off\_type}(-1)) \).
Table 152: newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios::end</td>
<td>seekhigh minus the beginning pointer (seekhigh - xbeg).</td>
</tr>
</tbody>
</table>

pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out) override;

Effects: Alters the stream position within one of the controlled sequences, if possible, to correspond to the stream position stored in sp (as described below).

(17.1) — If (which & ios::in) != 0, positions the input sequence.
(17.2) — If (which & ios::out) != 0, positions the output sequence.
(17.3) — If the function positions neither sequence, the positioning operation fails.

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines newoff from sp.offset():

(18.1) — If newoff is an invalid stream position, has a negative value, or has a value greater than (seekhigh - seeklow), the positioning operation fails.
(18.2) — Otherwise, the function adds newoff to the beginning pointer xbeg and stores the result in the next pointer xnext.

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

streambuf<char>* setbuf(char* s, streamsize n) override;

Effects: Behavior is implementation-defined, except that setbuf(0, 0) has no effect.

D.12.3 Class istrstream

namespace std {
    class istrstream : public basic_istream<char> {
        public:
            explicit istrstream(const char* s);
            explicit istrstream(char* s);
            istrstream(const char* s, streamsize n);
            istrstream(char* s, streamsize n);
            virtual ~istrstream();

            strstreambuf* rdbuf() const;
            char* str();

        private:
            strstreambuf sb; // exposition only
    };
}

The class istrstream supports the reading of objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

— sb, the strstreambuf object.

D.12.3.1 istrstream constructors

explicit istrstream(const char* s);
explicit istrstream(char* s);

Effects: Initializes the base class with istream(&sb) and sb with strstreambuf(s, 0). s shall designate the first element of an NTBS.
Effects: Initializes the base class with `istream(&sb)` and `sb` with `strstreambuf(s, n)`. `s` shall designate the first element of an array whose length is `n` elements, and `n` shall be greater than zero.

D.12.3.2 Member functions

```
strstreambuf* rdbuf() const;
```

1. *Returns:* `const_cast<strstreambuf*>(&sb)`.

```
char* str();
```

D.12.4 Class `ostrstream`

```
namespace std {
    class ostrstream : public basic_ostream<char> {
        public:
            ostrstream();
            ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
            virtual ~ostrstream();
            strstreambuf* rdbuf() const;
            void freeze(bool freezefl = true);
            char* str();
        private:
            strstreambuf sb;           // exposition only
        }
    }
```

1. The class `ostrstream` supports the writing of objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

   - `sb`, the `strstreambuf` object.

D.12.4.1 `ostrstream` constructors

```
ostrstream();
```

1. *Effects:* Initializes the base class with `ostream(&sb)` and `sb` with `strstreambuf()`.

```
ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
```

2. *Effects:* Initializes the base class with `ostream(&sb)`, and `sb` with one of two constructors:

   - If `(mode & app) == 0`, then `s` shall designate the first element of an array of `n` elements.
   
   The constructor is `strstreambuf(s, n, s)`.

   - If `(mode & app) != 0`, then `s` shall designate the first element of an array of `n` elements that contains an `NTBS` whose first element is designated by `s`. The constructor is `strstreambuf(s, n, s + std::strlen(s))`.329

D.12.4.2 Member functions

```
strstreambuf* rdbuf() const;
```

1. *Returns:* `(strstreambuf*)&sb`.

```
void freeze(bool freezefl = true);
```

2. *Effects:* Calls `rdbuf() -> freeze(freezefl)`.

```
char* str();
```

329 The function signature `strlen(const char*)` is declared in `<cstring>` (21.5.3).

§ D.12.4.2 1636
int pcount() const;

Returns: rdbuf() \rightarrow pcount().

D.12.5 Class `strstream`  

namespace std {
  class strstream
    : public basic_iostream<char> {
  public:
    // types
    using char_type = char;
    using int_type = char_traits<char>::int_type;
    using pos_type = char_traits<char>::pos_type;
    using off_type = char_traits<char>::off_type;

    // constructors/destructor
    strstream();
    strstream(char* s, int n,
              ios_base::openmode mode = ios_base::in|ios_base::out);
    virtual ~strstream();

    // members
    strstreambuf* rdbuf() const;
    void freeze(bool freezefl = true);
    int pcount() const;
    char* str();

  private:
    strstreambuf sb; // exposition only
  };
}

1 The class `strstream` supports reading and writing from objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

\[ \text{sb}, \text{the strstreambuf object.} \]

1.1 — sb, the `strstreambuf` object.

D.12.5.1 `strstream` constructors

strstream();

Effects: Initializes the base class with `iostream(&sb)`.

strstream(char* s, int n,
          ios_base::openmode mode = ios_base::in|ios_base::out);

Effects: Initializes the base class with `iostream(&sb)`, and `sb` with one of the two constructors:

1.1 — If `(mode & app) == 0`, then `s` shall designate the first element of an array of `n` elements. The constructor is `strstreambuf(s,n,s)`.

1.2 — If `(mode & app) != 0`, then `s` shall designate the first element of an array of `n` elements that contains an `NTBS` whose first element is designated by `s`. The constructor is `strstreambuf(s,n,s + std::strlen(s))`.

D.12.5.2 `strstream` destructor

virtual ~strstream();

Effects: Destroys an object of class `strstream`.

D.12.5.3 `strstream` operations

strstreambuf* rdbuf() const;

Returns: `const_cast<strstreambuf*>(&sb)`.

void freeze(bool freezefl = true);

Effects: Calls `rdbuf()->freeze(!!freezefl)`.
char* str();

Returns: rdbuf() ->str().

int pcount() const;

Returns: rdbuf() ->pcount().

D.13 Deprecated type traits

The header <type_traits> (20.15.2) has the following addition:

namespace std {
  template<class T> struct is_pod;
  template<class T> inline constexpr bool is_pod_v = is_pod<T>::value;
}

The behavior of a program that adds specializations for any of the templates defined in this subclause is undefined, unless explicitly permitted by the specification of the corresponding template.

template<class T> struct is_pod;

Requires: remove_all_extents_t<T> shall be a complete type or cv void.

is_pod<T> is a Cpp17UnaryTypeTrait (20.15.1) with a base characteristic of true_type if T is a POD type, and false_type otherwise. A POD class is a class that is both a trivial class and a standard-layout class, and has no non-static data members of type non-POD class (or array thereof). A POD type is a scalar type, a POD class, an array of such a type, or a cv-qualified version of one of these types.

[Note: It is unspecified whether a closure type (7.5.5.1) is a POD type. — end note]

D.14 Tuple

The header <tuple> (20.5.2) has the following additions:

namespace std {
  template<class T> class tuple_size<volatile T>;
  template<class T> class tuple_size<const volatile T>;
  template<size_t I, class T> class tuple_element<I, volatile T>;
  template<size_t I, class T> class tuple_element<I, const volatile T>;
}

template<class T> class tuple_size<volatile T>;

Let TS denote tuple_size<T> of the cv-unqualified type T. If the expression TS::value is well-formed when treated as an unevaluated operand, then specializations of each of the two templates meet the Cpp17TransformationTrait requirements with a base characteristic of integral_constant<size_t, TS::value>. Otherwise, they have no member value.

Access checking is performed as if in a context unrelated to TS and T. Only the validity of the immediate context of the expression is considered.

In addition to being available via inclusion of the <tuple> (20.5.2) header, the two templates are available when any of the headers <array> (22.3.2), <ranges> (24.2), or <utility> (20.2.1) are included.

template<size_t I, class T> class tuple_element<I, volatile T>;

Let TE denote tuple_element_t<I, T> of the cv-unqualified type T. Then specializations of each of the two templates meet the Cpp17TransformationTrait requirements with a member typedef type that names the following type:

(5.1) for the first specialization, add_volatile_t<TE>, and
(5.2) for the second specialization, add_cv_t<TE>.

In addition to being available via inclusion of the <tuple> (20.5.2) header, the two templates are available when any of the headers <array> (22.3.2), <ranges> (24.2), or <utility> (20.2.1) are included.
D.15 Variant

The header `<variant>` (20.7.2) has the following additions:

```cpp
namespace std {
    template<class T> struct variant_size<volatile T>;
    template<class T> struct variant_size<const volatile T>;

    template<size_t I, class T> struct variant_alternative<I, volatile T>;
    template<size_t I, class T> struct variant_alternative<I, const volatile T>;
}
```

Let `VS` denote `variant_size<T>` of the cv-unqualified type `T`. Then specializations of each of the two templates meet the `Cpp17UnaryTypeTrait` requirements with a base characteristic of `integral_constant<size_t, VS::value>`.

```cpp
template<size_t I, class T> class variant_alternative<I, volatile T>;
template<size_t I, class T> class variant_alternative<I, const volatile T>;
```

Let `VA` denote `variant_alternative<I, T>` of the cv-unqualified type `T`. Then specializations of each of the two templates meet the `Cpp17TransformationTrait` requirements with a member typedef `type` that names the following type:

1. For the first specialization, `add_volatile_t<VA::type>`, and
2. For the second specialization, `add_cv_t<VA::type>`.

D.16 Deprecated iterator primitives

D.16.1 Basic iterator

The header `<iterator>` (23.2) has the following addition:

```cpp
namespace std {
    template<class Category, class T, class Distance = ptrdiff_t,
        class Pointer = T*, class Reference = T&>
    struct iterator {
        using iterator_category = Category;
        using value_type = T;
        using difference_type = Distance;
        using pointer = Pointer;
        using reference = Reference;
    }
}
```

The iterator template may be used as a base class to ease the definition of required types for new iterators.

[Note: If the new iterator type is a class template, then these aliases will not be visible from within the iterator class’s template definition, but only to callers of that class. — end note]

[Example: If a C++ program wants to define a bidirectional iterator for some data structure containing `double` and such that it works on a large memory model of the implementation, it can do so with:

```cpp
class MyIterator :
    public iterator<bidirectional_iterator_tag, double, long, T*, T&> {
        // code implementing ++, etc.
    };
```

— end example]

D.17 Deprecated move_iterator access

The following member is declared in addition to those members specified in 23.5.3.5:

```cpp
namespace std {
    template<class Iterator>
    class move_iterator {
        public:
            constexpr pointer operator->() const;
    }
}
```
§ D.18 Deprecated shared_ptr atomic access  

The header `<memory>` (20.10.2) has the following additions:

```cpp
namespace std {
    template<class T>
    bool atomic_is_lock_free(const shared_ptr<T>* p);

template<class T>
    shared_ptr<T> atomic_load(const shared_ptr<T>* p);

template<class T>
    shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);

template<class T>
    void atomic_store(shared_ptr<T>* p, shared_ptr<T> r);

template<class T>
    void atomic_store_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

template<class T>
    shared_ptr<T> atomic_exchange(shared_ptr<T>* p, shared_ptr<T> r);

template<class T>
    shared_ptr<T> atomic_exchange_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

template<class T>
    bool atomic_compare_exchange_weak(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

template<class T>
    bool atomic_compare_exchange_strong(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

template<class T>
    bool atomic_compare_exchange_weak_explicit(
        shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
        memory_order success, memory_order failure);

template<class T>
    bool atomic_compare_exchange_strong_explicit(
        shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
        memory_order success, memory_order failure);
}
```

2 Concurrent access to a shared_ptr object from multiple threads does not introduce a data race if the access is done exclusively via the functions in this subclause and the instance is passed as their first argument.

3 The meaning of the arguments of type memory_order is explained in 31.4.

```
template<class T> bool atomic_is_lock_free(const shared_ptr<T>* p);
  
  Requires: p shall not be null.
  
  Returns: true if atomic access to *p is lock-free, false otherwise.
  
  Throws: Nothing.
```

```
template<class T> shared_ptr<T> atomic_load(const shared_ptr<T>* p);
  
  Requires: p shall not be null.
  
  Returns: atomic_load_explicit(p, memory_order::seq_cst).
  
  Throws: Nothing.
```

```
template<class T> shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);
  
  Requires: p shall not be null.
  
  Requires: mo shall not be memory_order::release or memory_order::acq_rel.
  
  Returns: *p.
```
template<class T> void atomic_store(shared_ptr<T>* p, shared_ptr<T> r);

requires: p shall not be null.
effects: As if by atomic_store_explicit(p, r, memory_order::seq_cst).
throws: Nothing.

template<class T> void atomic_store_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

requires: p shall not be null.
requires: mo shall not be memory_order::acquire or memory_order::acq_rel.
effects: As if by p->swap(r).
throws: Nothing.

template<class T> shared_ptr<T> atomic_exchange(shared_ptr<T>* p, shared_ptr<T> r);

requires: p shall not be null.
returns: atomic_exchange_explicit(p, r, memory_order::seq_cst).
throws: Nothing.

template<class T> shared_ptr<T> atomic_exchange_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

requires: p shall not be null.
effects: As if by p->swap(r).
returns: The previous value of *p.
throws: Nothing.

template<class T> bool atomic_compare_exchange_weak(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

requires: p shall not be null and v shall not be null.
returns: atomic_compare_exchange_weak_explicit(p, v, w, memory_order::seq_cst, memory_order::seq_cst)
throws: Nothing.

template<class T> bool atomic_compare_exchange_strong(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

returns: atomic_compare_exchange_strong_explicit(p, v, w, memory_order::seq_cst, memory_order::seq_cst)

template<class T>

bool atomic_compare_exchange_weak_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);

template<class T>

bool atomic_compare_exchange_strong_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);

requires: p shall not be null and v shall not be null. The failure argument shall not be memory_order::release
nor memory_order::acq_rel.
effects: If *p is equivalent to *v, assigns w to *p and has synchronization semantics corresponding to the value
of success, otherwise assigns *p to *v and has synchronization semantics corresponding to the value of
failure.
returns: true if *p was equivalent to *v, false otherwise.
throws: Nothing.
Remarks: Two shared_ptr objects are equivalent if they store the same pointer value and share ownership. The weak form may fail spuriously. See 31.8.1.

D.19 Deprecated basic_string capacity

The following member is declared in addition to those members specified in 21.3.2.4:

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_string {
        public:
            void reserve();
    };
}
```

Effects: After this call, capacity() has an unspecified value greater than or equal to size(). [Note: This is a non-binding shrink to fit request. — end note]

D.20 Deprecated standard code conversion facets

The header <codecvt> provides code conversion facets for various character encodings.

D.20.1 Header <codecvt> synopsis

```cpp
namespace std {
    enum codecvt_mode {
        consume_header = 4,
        generate_header = 2,
        little_endian = 1
    };

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf8 : public codecvt<Elem, char, mbstate_t> {
        public:
            explicit codecvt_utf8(size_t refs = 0);
            ~codecvt_utf8();
    };

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf16 : public codecvt<Elem, char, mbstate_t> {
        public:
            explicit codecvt_utf16(size_t refs = 0);
            ~codecvt_utf16();
    };

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf8_utf16 : public codecvt<Elem, char, mbstate_t> {
        public:
            explicit codecvt_utf8_utf16(size_t refs = 0);
            ~codecvt_utf8_utf16();
    }
}
```

D.20.2 Requirements

For each of the three code conversion facets codecvt_utf8, codecvt_utf16, and codecvt_utf8_utf16:

1. Elem is the wide-character type, such as wchar_t, char16_t, or char32_t.
2. Maxcode is the largest wide-character code that the facet will read or write without reporting a conversion error.
3. If (Mode & consume_header), the facet shall consume an initial header sequence, if present, when reading a multibyte sequence to determine the endianness of the subsequent multibyte sequence to be read.
If `(Mode & generate_header)`), the facet shall generate an initial header sequence when writing a multibyte sequence to advertise the endianness of the subsequent multibyte sequence to be written.

If `(Mode & little_endian)`), the facet shall generate a multibyte sequence in little-endian order, as opposed to the default big-endian order.

For the facet `codecvt_utf8`:

- The facet shall convert between UTF-8 multibyte sequences and UCS-2 or UTF-32 (depending on the size of `Elem`) within the program.
- Endianness shall not affect how multibyte sequences are read or written.
- The multibyte sequences may be written as either a text or a binary file.

For the facet `codecvt_utf16`:

- The facet shall convert between UTF-16 multibyte sequences and UCS-2 or UTF-32 (depending on the size of `Elem`) within the program.
- Multibyte sequences shall be read or written according to the `Mode` flag, as set out above.
- The multibyte sequences may be written only as a binary file. Attempting to write to a text file produces undefined behavior.

For the facet `codecvt_utf8_utf16`:

- The facet shall convert between UTF-8 multibyte sequences and UTF-16 (one or two 16-bit codes) within the program.
- Endianness shall not affect how multibyte sequences are read or written.
- The multibyte sequences may be written as either a text or a binary file.

The encoding forms UTF-8, UTF-16, and UTF-32 are specified in ISO/IEC 10646. The encoding form UCS-2 is specified in ISO/IEC 10646-1:1993.

D.21 Deprecated convenience conversion interfaces

The header `<locale>` (28.2) has the following additions:

```cpp
namespace std {
    template<class Codecvt, class Elem = wchar_t,
            class WideAlloc = allocator<Elem>,
            class ByteAlloc = allocator<char>>
    class wstring_convert;

    template<class Codecvt, class Elem = wchar_t,
             class Tr = char_traits<Elem>>
    class wbuffer_convert;
}
```

D.21.1 Class template wstring_convert

Class template `wstring_convert` performs conversions between a wide string and a byte string. It lets you specify a code conversion facet (like class template `codecvt`) to perform the conversions, without affecting any streams or locales. [Example: If you want to use the code conversion facet `codecvt_utf8` to output to `cout` a UTF-8 multibyte sequence corresponding to a wide string, but you don’t want to alter the locale for `cout`, you can write something like:

```cpp
wstring_convert<std::codecvt_utf8<wchar_t>> myconv;
std::string mbstring = myconv.to_bytes(L"Hello\n");
std::cout << mbstring;
```

end example]}

```cpp
namespace std {
    template<class Codecvt, class Elem = wchar_t,
             class WideAlloc = allocator<Elem>,
             class ByteAlloc = allocator<char>>
    class wstring_convert {
    public:
        using byte_string = basic_string<char, char_traits<char>, ByteAlloc>;
        using wide_string = basic_string<Elem, char_traits<Elem>, WideAlloc>;
    }
}
```
using state_type = typename Codecvt::state_type;
using int_type = typename wide_string::traits_type::int_type;

wstring_convert() : wstring_convert(new Codecvt) {}
explicit wstring_convert(Codecvt* pcvt);
wstring_convert(Codecvt* pcvt, state_type state);
explicit wstring_convert(const byte_string& byte_err, 
const wide_string& wide_err = wide_string());
~wstring_convert();

wstring_convert(const wstring_convert&) = delete;
wstring_convert& operator=(const wstring_convert&) = delete;

wide_string from_bytes(char byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);

byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);

size_t converted() const noexcept;
state_type state() const;

private:
  byte_string byte_err_string; // exposition only
  wide_string wide_err_string; // exposition only
  Codecvt* cvtptr; // exposition only
  state_type cvtstate; // exposition only
  size_t cvtcount; // exposition only
};

The class template describes an object that controls conversions between wide string objects of class basic_string<Elem, char_traits<Elem>, WideAlloc> and byte string objects of class basic_string<char, char_traits<char>, ByteAlloc>. The class template defines the types wide_string and byte_string as synonyms for these two types. Conversion between a sequence of Elem values (stored in a wide_string object) and multi-byte sequences (stored in a byte_string object) is performed by an object of class Codecvt, which meets the requirements of the standard code-conversion facet codecvt<Elem, char, mbstate_t>.

An object of this class template stores:

1. byte_err_string — a byte string to display on errors
2. wide_err_string — a wide string to display on errors
3. cvtptr — a pointer to the allocated conversion object (which is freed when the wstring_convert object is destroyed)
4. cvtstate — a conversion state object
5. cvtcount — a conversion count

using byte_string = basic_string<char, char_traits<char>, ByteAlloc>;

The type shall be a synonym for basic_string<char, char_traits<char>, ByteAlloc>.

size_t converted() const noexcept;

Returns: cvtcount.

wide_string from_bytes(char byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);

Effects: The first member function shall convert the single-element sequence byte to a wide string. The second member function shall convert the null-terminated sequence beginning at ptr to a wide string. The third member function shall convert the sequence stored in str to a wide string. The fourth member function shall convert the sequence defined by the range [first, last) to a wide string.

In all cases:

(7.1) If the cvtstate object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(7.2) The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted wide string. Otherwise, if the object was constructed with a wide-error string, the member function shall return the wide-error string. Otherwise, the member function throws an object of class range_error.

using int_type = typename wide_string::traits_type::int_type;

The type shall be a synonym for wide_string::traits_type::int_type.

state_type state() const;

Returns: cvtstate.

using state_type = typename Codecvt::state_type;

The type shall be a synonym for Codecvt::state_type.

byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);

Effects: The first member function shall convert the single-element sequence wchar to a byte string. The second member function shall convert the null-terminated sequence beginning at wptr to a byte string. The third member function shall convert the sequence stored in wstr to a byte string. The fourth member function shall convert the sequence defined by the range [first, last) to a byte string.

In all cases:

(13.1) If the cvtstate object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(13.2) The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted byte string. Otherwise, if the object was constructed with a byte-error string, the member function shall return the byte-error string. Otherwise, the member function shall throw an object of class range_error.

using wide_string = basic_string<Elem, char_traits<Elem>, WideAlloc>;

The type shall be a synonym for basic_string<Elem, char_traits<Elem>, WideAlloc>.

explicit wstring_convert(Codecvt* pcvt);
wstring_convert(Codecvt* pcvt, state_type state);
explicit wstring_convert(const byte_string& byte_err, const state_type& state, const wide_string& wide_err);
const wide_string& wide_err = wide_string();

Requires: For the first and second constructors, pcvt != nullptr.

Effects: The first constructor shall store pcvt in cvtptr and default values in cvtstate, byte_err_string, and wide_err_string. The second constructor shall store pcvt in cvtptr, state in cvtstate, and default values in byte_err_string and wide_err_string; moreover the stored state shall be retained between calls to from_bytes and to_bytes. The third constructor shall store new Codecvt in cvtptr, state_type() in cvtstate, byte_err in byte_err_string, and wide_err in wide_err_string.

Wstring_convert();

Effects: The destructor shall delete cvtptr.
D.21.2  Class template wbuffer_convert  [depr.conversions.buffer]

1 Class template wbuffer_convert looks like a wide stream buffer, but performs all its I/O through an underlying byte stream buffer that you specify when you construct it. Like class template wstring_convert, it lets you specify a code conversion facet to perform the conversions, without affecting any streams or locales.

namespace std {
    template<class Codecvt, class Elem = wchar_t, class Tr = char_traits<Elem>>
    class wbuffer_convert : public basic_streambuf<Elem, Tr> {
        public:
            using state_type = typename Codecvt::state_type;
            wbuffer_convert() : wbuffer_convert(nullptr) {}  
            explicit wbuffer_convert(streambuf* bytebuf,  
                Codecvt* pcvt = new Codecvt,  
                state_type state = state_type());
            ~wbuffer_convert();
            wbuffer_convert(const wbuffer_convert&) = delete;
            wbuffer_convert& operator=(const wbuffer_convert&) = delete;
            streambuf* rdbuf() const;
            streambuf* rdbuf(streambuf* bytebuf);
            state_type state() const;
        private:
            streambuf* bufptr;  // exposition only
            Codecvt* cvtptr;   // exposition only
            state_type cvtstate;  // exposition only
        }
    }

2 The class template describes a stream buffer that controls the transmission of elements of type Elem, whose character traits are described by the class Tr, to and from a byte stream buffer of type streambuf. Conversion between a sequence of Elem values and multibyte sequences is performed by an object of class Codecvt, which shall meet the requirements of the standard code-conversion facet codecvt<Elem, char, mbstate_t>.

3 An object of this class template stores:

(1.1) — bufptr — a pointer to its underlying byte stream buffer
(1.2) — cvtptr — a pointer to the allocated conversion object (which is freed when the wbuffer_convert object is destroyed)
(1.3) — cvtstate — a conversion state object

4 state_type state() const;
    Returns: cvtstate.

5 streambuf* rdbuf() const;
    Returns: bufptr.

6 streambuf* rdbuf(streambuf* bytebuf);
    Effects: Stores bytebuf in bufptr.
    Returns: The previous value of bufptr.

7 using state_type = typename Codecvt::state_type;
    The type shall be a synonym for Codecvt::state_type.

8 explicit wbuffer_convert(
    streambuf* bytebuf,  
    Codecvt* pcvt = new Codecvt,
state_type state = state_type();

Requires: pcvt != nullptr.
Effects: The constructor constructs a stream buffer object, initializes bufptr to bytebuf, initializes cvtptr to pcvt, and initializes cvtstate to state.

~wbuffer_convert();

Effects: The destructor shall delete cvtptr.

D.22 Deprecated locale category facets

The ctype locale category includes the following facets as if they were specified in Table 102 of 28.3.1.1.1.

codecvt<char16_t, char, mbstate_t>
codecvt<char32_t, char, mbstate_t>

The ctype locale category includes the following facets as if they were specified in Table 103 of 28.3.1.1.1.

codecvt_byname<char16_t, char, mbstate_t>
codecvt_byname<char32_t, char, mbstate_t>

The following class template specializations are required in addition to those specified in 28.4.1.4. The specialization codecvt<char16_t, char, mbstate_t> converts between the UTF-16 and UTF-8 encoding forms, and the specialization codecvt<char32_t, char, mbstate_t> converts between the UTF-32 and UTF-8 encoding forms.

D.23 Deprecated filesystem path factory functions

template<class Source>
path u8path(const Source& source);
template<class InputIterator>
path u8path(InputIterator first, InputIterator last);

Requires: The source and [first, last) sequences are UTF-8 encoded. The value type of Source and InputIterator is char or char8_t. Source meets the requirements specified in 29.11.7.3.

Returns:
(2.1) — If value_type is char and the current native narrow encoding (29.11.7.2.2) is UTF-8, return path(source) or path(first, last); otherwise,
(2.2) — if value_type is wchar_t and the native wide encoding is UTF-16, or if value_type is char16_t or char32_t, convert source or [first, last) to a temporary, tmp, of type string_type and return path(tmp); otherwise,
(2.3) — convert source or [first, last) to a temporary, tmp, of type u32string and return path(tmp).

Remarks: Argument format conversion (29.11.7.2.1) applies to the arguments for these functions. How Unicode encoding conversions are performed is unspecified.

[Example: A string is to be read from a database that is encoded in UTF-8, and used to create a directory using the native encoding for filenames:

namespace fs = std::filesystem;
std::string utf8_string = read_utf8_data();
fs::create_directory(fs::u8path(utf8_string));

For POSIX-based operating systems with the native narrow encoding set to UTF-8, no encoding or type conversion occurs.

For POSIX-based operating systems with the native narrow encoding not set to UTF-8, a conversion to UTF-32 occurs, followed by a conversion to the current native narrow encoding. Some Unicode characters may have no native character set representation.

For Windows-based operating systems a conversion from UTF-8 to UTF-16 occurs. — end example] [Note: The example above is representative of a historical use of filesystem::u8path. Passing a std::u8string to path’s constructor is preferred for an indication of UTF-8 encoding more consistent with path’s handling of other encodings. — end note]

D.24 Deprecated atomic operations

The header <atomic> (31.2) has the following additions.
namespace std {
    template<class T>
    void atomic_init(volatile atomic<T>*, typename atomic<T>::value_type) noexcept;
    template<class T>
    void atomic_init(atomic<T>*, typename atomic<T>::value_type) noexcept;

#define ATOMIC_VAR_INIT(value) see below

#define ATOMIC_FLAG_INIT see below
}

D.24.1 Volatile access  

If an atomic specialization has one of the following overloads, then that overload participates in overload resolution even if atomic<T>::is_always_lock_free is false:

- void store(T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
- T operator=(T desired) volatile noexcept;
- T load(memory_order order = memory_order::seq_cst) const volatile noexcept;
- operator T() const volatile noexcept;
- T exchange(T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
- bool compare_exchange_weak(T& expected, T desired, memory_order success, memory_order failure) volatile noexcept;
- bool compare_exchange_strong(T& expected, T desired, memory_order success, memory_order failure) volatile noexcept;
- bool compare_exchange_weak(T& expected, T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
- bool compare_exchange_strong(T& expected, T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
- T fetch_key(T operand, memory_order order = memory_order::seq_cst) volatile noexcept;
- T operator op=(T operand) volatile noexcept;
- T* fetch_key(ptrdiff_t operand, memory_order order = memory_order::seq_cst) volatile noexcept;

D.24.2 Non-member functions  

Effects: Equivalent to: atomic_store_explicit(object, desired, memory_order::relaxed);

D.24.3 Operations on atomic types  

The macro expands to a token sequence suitable for constant initialization of an atomic variable of static storage duration of a type that is initialization-compatible with value. [Note: This operation may need to initialize locks. — end note] Concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race. [Example:

    atomic<int> v = ATOMIC_VAR_INIT(5);

— end example]

D.24.4 Flag type and operations  

Remarks: The macro ATOMIC_FLAG_INIT is defined in such a way that it can be used to initialize an object of type atomic_flag to the clear state. The macro can be used in the form:

    atomic_flag guard = ATOMIC_FLAG_INIT;

It is unspecified whether the macro can be used in other initialization contexts. For a complete static-duration object, that initialization shall be static.
The following documents are cited informatively in this document.

- IANA Time Zone Database, available at https://www.iana.org/time-zones
- ISO 4217:2015, Codes for the representation of currencies

The arithmetic specification described in ISO/IEC 10967-1:2012 is called LIA-1 in this document.
### Cross references

This annex lists each clause or subclause label and the corresponding clause or subclause number and page number, in alphabetical order by label.

execution, 11
width, 67, 261, 708
worse conversion sequence, see conversion sequence,
worse

X
xor, 16
xor_eq, 16
xvalue, 83

Y
$Y^\ell_m$ (spherical associated Legendre functions), 1197
yield-expression, 132, 1585

Z
zero
division by undefined, 82
remainder undefined, 82
undefined division by, 126
zero-initialization, 182
zeta functions $\zeta$, 1197
Index of grammar productions

The first bold page number for each entry is the page in the general text where the grammar production is defined. The second bold page number is the corresponding page in the Grammar summary (Annex A). Other page numbers refer to pages where the grammar production is mentioned in the general text.

abstract-declarator, 169, 170, 176, 179, 1589
abstract-pack-declarator, 169, 1590
access-specifier, 266, 266, 278, 279, 1594

Index of library concepts 1787
1013–1016, 1020–1023, 1029, 1030,
1032–1034, 1054–1057, 1059, 1064,
1066–1069, 1080, 1081, 1084–1087
Index of implementation-defined behavior

The entries in this index are rough descriptions; exact specifications are at the indicated page in the general text.

#pragma, 439
additional execution policies supported by parallel algorithms, 700, 1004
additional file_type enumerators for file systems supporting additional types of file, 1429
additional formats for time_get::do_get_date, 1317
additional supported forms of preprocessing directive, 428
algorithms for producing the standard random number distributions, 1148
alignment, 62
alignment additional values, 62
alignment of bit-fields within a class object, 261
allocation of bit-fields within a class object, 261
any use of an invalid pointer other than to perform indirection or deallocate, 59
argument values to construct ios_base::failure, 1344
assignability of placeholder objects, 665
behavior of iostream classes when
traits::pos_type is not streampos or
when traits::off_type is not streamoff, 1328
behavior of non-standard attributes, 222
behavior of strstreambuf::setbuf, 1635
bits in a byte, 53
choice of larger or smaller value of floating-point-literal, 21
concatenation of some types of string-literals, 22
conversions between pointers and integers, 113
converting characters from source character set to execution character set, 10
converting function pointer to object pointer and vice versa, 114
default configuration of a pool, 644
default next_buffer_size for a monotonic_buffer_resource, 645
default number of buckets in unordered_map, 849
default number of buckets in unordered_multimap, 855
default number of buckets in unordered_multiset, 864
default number of buckets in unordered_set, 860
defining main in freestanding environment, 78
definition and meaning of __STDC__, 441, 1625
definition and meaning of __STDC_VERSION__, 441
definition of NULL, 475, 1626
derived type for typeid, 111
diagnostic message, 3
dynamic initialization of static inline variables before main, 81
dynamic initialization of static variables before main, 80, 81
dynamic initialization of thread-local variables before entry, 81
effect of calling associated Laguerre polynomials with n \geq 128 or n \geq 128, 1193
effect of calling associated Legendre polynomials with l \geq 128, 1193
effect of calling basic_filebuf::setbuf with nonzero arguments, 1396
effect of calling basic_filebuf::sync when a get area exists, 1397
effect of calling basic_streambuf::setbuf with nonzero arguments, 1384
effect of calling cylindrical Bessel functions of the first kind with nu \geq 128, 1194
effect of calling cylindrical Neumann functions with nu \geq 128, 1195
effect of calling Hermite polynomials with n \geq 128, 1196
effect of calling ios_base::sync_with_stdio after any input or output operation on standard streams, 1338
effect of calling irregular modified cylindrical Bessel functions with nu \geq 128, 1195
effect of calling Laguerre polynomials with n \geq 128, 1196
effect of calling Legendre polynomials with l \geq 128, 1196
effect of calling regular modified cylindrical Bessel functions with nu \geq 128, 1194
effect of calling spherical associated Legendre functions with l \geq 128, 1197
effect of calling spherical Bessel functions with n \geq 128, 1197
effect of calling spherical Neumann functions with nu \geq 128, 1198
effect of filesystem::copy, 1441
effect on C locale of calling locale::global, 1294
encoding of universal character name not in execution character set, 20
error_category for errors originating outside the operating system, 472
exception type when random_device constructor fails, 1145
exception type when random_device::operator() fails, 1146
Index of impl.-def. behavior 1789
exception type when `shared_ptr` constructor fails, 626

exceptions thrown by standard library functions that have a potentially-throwing exception specification, 471

execution character set and execution wide-character set, 11

exit status, 489

extended signed integer types, 67

file type of the file argument of `filesystem::status`, 1451

formatted character sequence generated by `time_put::do_put` in C locale, 1319

forward progress guarantees for implicit threads of parallel algorithms (if not defined for thread), 1003

growth factor for `monotonic_buffer_resource`, 645

headers for freestanding implementation, 455

how `random_device::operator()` generates values, 1145

how the set of importable headers is determined, 232

interactive device, 8

interpretation of the path character sequence with `format path::auto_format`, 1428

largest supported value to configure the largest allocation satisfied directly by a pool, 643

largest supported value to configure the maximum number of blocks to replenish a pool, 643

linkage of `main`, 79

linkage of names from C standard library, 456

linkage of objects between C++ and other languages, 221

locale names, 1293

lvalue-to-rvalue conversion of an invalid pointer value, 87

manner of search for included source file, 431

mapping from name to catalog when calling `messages::do_open`, 1325

mapping from physical source file characters to basic source character set, 11, 1607

mapping header name to header or external source file, 14

mapping of pointer to integer, 113

mapping physical source file characters to basic source character set, 10

mapping to message when calling `messages::do_get`, 1325

maximum depth of recursive template instantiations, 393

maximum size of an allocated object, 120, 494

meaning of ``, `\`, `/`, `*`, or `/` in a `q-char-sequence` or an `h-char-sequence`, 14

meaning of `asm` declaration, 218

meaning of attribute declaration, 151

meaning of dot-dot in `root-directory`, 1416

negative value of `character-literal` in preprocessor, 430

nesting limit for `#include` directives, 432

NTCTS in `basic_ostream<charT, traits>& operator<<(nullptr_t)`, 1371

number of placeholders for bind expressions, 651, 665

number of threads in a program under a freestanding implementation, 74

numeric values of `character-literals` in `#if` directives, 430

operating system on which implementation depends, 1408

parameters to `main`, 79

passing argument of class type through ellipsis, 108

physical source file characters, 10

presence and meaning of `native_handle_type` and `native_handle`, 1519

range defined for `character-literals`, 19

rank of extended signed integer type, 71

required alignment for `atomic_ref` type’s operations, 1495, 1498–1500

required libraries for freestanding implementation, 7

resource limits on a message catalog, 1325

result of `filesystem::file_size`, 1446

result of inexact floating-point conversion, 89

return value of `bad_alloc::what`, 494

return value of `bad_any_cast::what`, 589

return value of `bad_array_new_length::what`, 494

return value of `bad_cast::what`, 452

return value of `bad_exception::what`, 501

return value of `bad_function_call::what`, 666

return value of `bad_optional_access::what`, 575

return value of `bad_typeid::what`, 497

return value of `bad_variant_access::what`, 588

return value of `bad_weak_ptr::what`, 624

return value of `char_traits<char16_t>::eof`, 725

return value of `char_traits<char32_t>::eof`, 725

return value of `exception::what`, 457

return value of `type_info::name()`, 497

search locations for "" header, 432

search locations for `<` header, 431

semantics of an access through a volatile glvalue, 160

semantics of linkage specification on templates, 336

semantics of linkage specifiers, 218

semantics of non-standard escape sequences, 19

semantics of parallel algorithms invoked with implementation-defined execution policies, 1004

semantics of `token` parameter and default token value used by `random_device` constructors, 1145

sequence of places searched for a header, 431

set of character types that iostreams templates can be instantiated for, 1291, 1328

Index of impl.-def. behavior

1790
signedness of char, 161
sizeof applied to fundamental types other than
char, signed char, and unsigned char, 118
stack unwinding before call to std::terminate, 423,
426
startup and termination in freestanding environment,
78
strict total order over pointer values, 445
string resulting from __func__, 197
support for always lock-free integral atomic types in
freestanding environments, 455
support for extended alignments, 62
support for module#import-declarations with non-C++
language linkage, 219
supported multibyte character encoding rules, 723
supported root-names in addition to any operating
system dependent root-names, 1416
text of __DATE__ when date of translation is not
available, 440
text of __TIME__ when time of translation is not
available, 440
threads and program points at which deferred
dynamic initialization is performed, 80, 81
type aliases atomic_signed_lock_free and
atomic_unsigned_lock_free in
freestanding environments, 455
type of a directory-like file, 1435, 1437
type of array::const_iterator, 801
type of array::iterator, 801
type of basic_string::const_iterator, 729
type of basic_string::iterator, 729
type of basic_string_view::const_iterator,
753, 755
type of default_random_engine, 1145
type of deque::const_iterator, 804
type of deque::iterator, 804
type of forward_list::const_iterator, 807
type of forward_list::iterator, 807
type of list::const_iterator, 813
type of list::iterator, 813
type of map::const_iterator, 828
type of map::iterator, 828
type of multimap::const_iterator, 833
type of multimap::iterator, 833
type of multiset::const_iterator, 840
type of multiset::iterator, 840
type of ptdiff_t, 127, 476
type of regex_constants::error_type, 1463
type of regex_constants::match_flag_type,
1462
type of set::const_iterator, 837
type of set::iterator, 837
type of size_t, 476
type of span::iterator, 873, 878
type of syntax_option_type, 1461
type of unordered_map::const_iterator, 845
type of unordered_map::const_local_iterator,
845
type of unordered_map::iterator, 845
type of unordered_map::local_iterator, 845
type of unordered_multimap::const_iterator,
852
type of unordered_multimap::const_local_iterator,
852
type of unordered_multimap::iterator, 852
type of unordered_multimap::local_iterator,
852
type of unordered_multiset::const_iterator,
861
type of unordered_multiset::const_local_iterator,
861
type of unordered_multiset::iterator, 861
type of unordered_multiset::local_iterator,
861
type of unordered_set::const_iterator, 856
type of unordered_set::const_local_iterator,
856
type of unordered_set::iterator, 856
type of unordered_set::local_iterator, 856
type of vector::const_iterator, 819
type of vector::iterator, 819
type of vector<bool>::const_iterator,
823
type of vector<bool>::iterator, 823
underlying type for enumeration, 205
underlying type of bool, 68
underlying type of char, 68
underlying type of wchar_t, 68
unit suffix when Period::type is micro, 1221
value for least_max_value default template
argument of counting_semaphore, 1558
value of bit-field that cannot represent
assigned value, 134
incremented value, 109
initializer, 185
value of character-literal outside range of
corresponding type, 19
value of ctype<char>::table_size, 1299
value of has_attribute_expression for non-standard
attributes, 430
value of multicharacter literal, 19
value of pow(0,0), 1124
value of result of inexact integer to floating-point
conversion, 89
value of wide-character literal containing multiple
characters, 19
value of wide-character literal with single c-char that
is not in execution wide-character set, 19
value representation of floating-point types, 69
value representation of pointer types, 70
values of a trivially copyable type, 66
values of various \texttt{ATOMIC\_\ldots\_LOCK\_FREE} macros, 1494

whether \texttt{<cfenv>} functions can be used to manage floating-point status, 1117
whether a given atomic type’s operations are always lock free, 1501, 1502, 1505, 1507, 1509, 1511, 1514
whether a given \texttt{atomic\_ref} type’s operations are always lock free, 1495, 1498–1500
whether an implementation has relaxed or strict pointer safety, 62
whether functions from Annex K of the C standard library are declared when C++ headers are included, 454
whether \texttt{get\_pointer\_safety} returns \texttt{pointer\_safety::relaxed} or \texttt{preferred} if the implementation has relaxed pointer safety, 608
whether locale object is global or per-thread, 1291
whether \texttt{pragma FENV\_ACCESS} is supported, 1117
whether \texttt{rand} may introduce a data race, 1164
whether sequence pointers are copied by \texttt{basic\_filebuf} move constructor, 1393
whether sequence pointers are copied by \texttt{basic\_stringbuf} move constructor, 1380
whether sequence pointers are initialized to null pointers, 1379
whether source file inclusion of importable header is replaced with \texttt{import} directive, 432
whether source of translation units must be available to locate template definitions, 11
whether stack is unwound before calling the function \texttt{std::terminate} when a noexcept specification is violated, 426
whether the implementation is hosted or freestanding, 455
whether the lifetime of a parameter ends when the callee returns or at the end of the enclosing full-expression, 107
whether the sources for module units and header units on which the current translation unit has an interface dependency are required to be available during translation, 11
whether the thread that executes \texttt{main} and the threads created by \texttt{std::thread} or \texttt{std::jthread} provide concurrent forward progress guarantees, 78
whether \texttt{time\_get\_::do\_get\_year} accepts two-digit year numbers, 1317
whether values are rounded or truncated to the required precision when converting between \texttt{time\_t} values and \texttt{time\_point} objects, 1225
which functions in the C++ standard library may be recursively reentered, 470
which non-standard-layout objects containing no data are considered empty, 54
